PREFACE.

INDEX-LEARNING, which

‘turns no student pale,
Yet holds the eel of science by the tail,’

has long been held in contempt by scholars and in derision by wits; and the use of encyclopædias is sometimes thought, therefore, to be condemned. Nobody searches the files of *The Eutanswill Gazette* for that review on Chinese metaphysics by the young man who looked up metaphysics under M and China under C, and ‘combined his information.’ Some encyclopædias have aimed at superseding all other books. Jean de Magnon, dedicating his labour to the glory of God, gave up the writing of tragedy to compose such a one in French verse. ‘Death alone,’ he said, ‘will see the end of my undertaking, which is to give you in ten volumes of twenty thousand lines apiece, a complete body of knowledge, so well conceived and so well set forth, that libraries will be nothing more to you than a useless ornament.’ Thanks to an assassin who took him at his word, we have got off with some few thousands of lines, published in 1663. Even worse was the *Yung Lo Ta Tien*, which had lived half a millennium in eleven thousand volumes of Chinese manuscript before the Boxer incendiaries put an end to all danger of its going to press.

Other encyclopædias there are which give no help towards the making of superfluous books, or the making of books superfluous, save so far as their own superfluity goes. They achieve brevity by omitting all that the consultant is likely to wish to learn, all that he is not likely to know already.

Between these two extremes, *Chambers's Encyclopædia* has a character of its own. It strives to be at once comprehensive, compact, accurate, lucid, readable, and handy for reference. The larger themes are broken up into many articles; but provision is throughout made for securing a systematic conspectus of the whole subject. Thus the article GEOLOGY gives a history of the science, and plans out the whole field; while the reader in search of information on single items, such as Plesiosaurus, Boulder Clay, Denudation, Caves, Pitch-stone, Greensand, Mammoth, Coprolites, Dykes, Trilobites, Pterodactyl, the Antiquity of Man, will not have to hunt for these hidden in a trackless wilderness of continuous dissertation, but will find each under its several head. Nor are the articles all so very short as they are sometimes assumed to be. Many of them are equal to forty or fifty pages of a treatise; and the whole, as the increase of knowledge and the unfolding of history warrant, dwarfs Jean de Magnon's conception. We may claim that our assiduous readers will hold the eel of science a good way up the tail; and a glance at the bibliographies which end very many of the articles will prove that we indicate how to exchange that grip for a securer and more comprehensive. We do not desire to be to our readers what our predecessor and namesake Ephraim Chambers was to Doctor Morosophos, whose own book turned out to be but

‘CHAMBERS ABRIDG'D! In sooth 'twas all he read
From fruitful A to unproductive Zed.’

ARCHPRIEST.....	T. G. LAW, LL.D.	BEAST FABLES... ..	THOMAS DAVIDSON.
ARCTIC OCEAN.....	Sir JOHN MURRAY, K.C.B.		
ARGON.....	LEONARD DOBBIN, Ph.D.		

A great many of the articles named above are new; others written for earlier issues of this Encyclopædia have been so thoroughly revised by their authors as to be virtually new. In addition to these, many other revisers have taken part, including Professor J. A. S. WATSON (on Agriculture), Mr CHARLES MORRIS (America), Mr C. INGLIS CLARK and Mr WILLIAM MORISON (Chemistry), Sheriff IRVINE and Sir THOMAS RALEIGH (Law), Professor WILLIAM PEDDIE (Mathematics and Physics), Mr R. C. MOSSMAN (Meteorology), Dr JOHN D. COMRIE (Medicine), Captain H. M. JOHNSTONE, R.E. (Military Subjects), Admiral Sir REGINALD TUPPER, K.C.B. (Naval Subjects).

CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

the first letter of our alphabet, represents historically the first letter of the western Semitic alphabet of twenty-two consonants. Its original sound, still preserved in Arabic, was the 'glottal catch' or 'gasp,' which, though not unknown in European languages (in German it is prefixed to all stressed initial vowels), is not recognised by non-Semitic ears as an articulate sound at all. Hence in popular transcriptions of Semitic words it is left unwritten, as in the Bible names Adam, Enosh, Ichabod, Onan, Uriah, all which in Hebrew begin with this letter. In more scientific transcription this consonant is often represented by (').

The name of the letter, in Hebrew *'ālef*, in Syriac *'oluf*, in Arabic *'alif*, and in some early Semitic dialect *'alpa* (whence the Greek *alpha*), appears to be identical with the word for ox (Assyrian *'alpu*, Hebrew *'elef*). Its earliest known form was , which looks like a rude outline of an ox's head. Whether this was the origin of the form cannot now be determined. In later Semitic writing the shape of the letter was gradually altered in various directions; in late Hebrew it is , and in Arabic .

Unlike the Semitic tongues, the Greek language did not admit of being intelligibly written without vowels. Hence, when the Greeks adopted the Semitic alphabet, they used the first letter for the vowel-sound with which, in their pronunciation, its name *alpha* began—viz. the vowel which occurs long in the English *calm*, *father*, and short in the Scottish pronunciation of *man*. In early Greek inscriptions the letter had some varieties of shape, but the form *A* ultimately became general.

The Romans adopted the Greek *A* without change of form or phonetic value, but for the name *alpha* they substituted *ā*. In late Latin *ae*, *au* were pronounced as simple long vowels, like our *e*, *o* in *there*, *form*; otherwise the sound of the letter remained unchanged.

In those European languages that use the Roman alphabet, English only excepted, *A* still normally has nearly or exactly its Latin sound. In English since the 14th century the pronunciation has changed more quickly than the spelling, so that now the letter represents several distinct sounds (name, *care*, *father*, *all*, *hat*, *amend*). It also occurs as a component of the digraphs *ae*, *ai*, *ay*, *au*, *aw*, *ea*, *oa*, which represent simple vowels, and all (except *aw*) have more than one phonetic value. Our so-called 'long *a*'—the sound which serves as the name of the letter—is the diphthong which the Romans wrote *ei*.

In most of the modern languages in which *A* usually has its Latin sound, it has also other values in particular collocations. In French the letter has two normal sounds (*âge*, *rage*), and *ai*, *au* represent simple vowels. In German *ae* (commonly written *a*, formerly *ä*) is pronounced like *e* (but sometimes more open); so also *æ* in Danish and *a* in Swedish; the Icelandic *æ* resembles our *i* in *time*. The Danish *aa* and Swedish *å* are sounded nearly like *a* in *all*. In Icelandic *a* has the sound of *ou* in *house*, and *au* that of *oy* in *boy*.

The Roman *A* had an easier form *Δ*, which in medieval MSS. was rounded to *α*, *ɑ*, whence our italic and script *a*. In some hands a curve was substituted for the right-hand stroke, yielding the forms imitated in print as *ā*, *ɑ*; in others the letter was written *ɑ*, and this form, with the prefixed flourish distinctive of capitals, developed into the German printed *A*.

The medieval practice of rendering *ae*, when occurring in the same syllable, by a ligature (*Æ*, *æ*; in 16th-century print sometimes *ə*) prevailed in this country in written and printed Latin until quite recently, but is now discarded. In English the ligature is still very commonly used in those words of classical origin (e.g. *æsthetic*) in the spelling of which the *ae* has not given place to *e*, but many of our printers have ceased to use it.

Fuller information about *A* and the other letters will

be found in the articles ALPHABET, HIEROGLYPHICS, RUNES, WRITING. A is naturally used in many ways as a symbol for the first of a series, as in music (see MUSIC, PITCH, SCALE); as one of the Numerals (q.v.); in algebraic and geometric reasoning; in logic; as one of the Domical Letters (q.v.). It appears in many Abbreviations (q.v.); A1 is explained at LLOYD'S.

Aa, the name of a number of small rivers in Europe. For its etymology, see AACHEN.

Aa, a Hawaiian word adopted by geologists to denote a rugged lava, in which the surface has rapidly consolidated, and has been broken up into clinkers, and tumbled about by the flow of the stream.

Aabenraa (Ger. *Apenrade*), a town in Danish Sleswick (till 1920 Prussian), at the head of a gulf in the Little Belt (*Apenade Fjord*), 66 miles NNW. of Kiel, has a court-house, a school of navigation, and an excellent harbour, with a considerable amount of shipping; pop. 7000.

Aachen, the German name for Aix-la-Chapelle (q.v.), contains a root believed to be Celtic, but certainly identical with Gothic *ahwa*, Old English *ea*, Old Norse *á*, Old High German *Aha*, and Latin *agua*. *Aix* is from *agua*, through *Agues*. Many small European rivers are called Aa or Ach, and the root occurs in many German place-names, such as Biberach, Biebrich, and Fulda. The Old English word survives in the Lancashire dialect word *ea*, 'watercourse,' 'stream.'

Aahmes, king of Egypt, known by his Greek name of Amasis (q.v.).

Aal, ACH, Hindustani names for *Morinda*, a tropical genus of plants of the family Rubiaceae. The flowers are grouped in heads, with ovaries united. *M. citrifolia* and *M. tinctoria* are cultivated in India for the dull reddish dye prepared from the wood and roots, depending for its properties on a glucoside *morindin*. It is believed to protect cloth against termites. Some species are used medicinally in Africa, especially for fever.

Aaland Islands. See ÅLAND ISLANDS.

Aalborg, a seaport in the north of Jutland, on the south side of the Liimfiord, and 90 miles by rail from Aarhus. It has two old churches and a castle, and is the seat of a bishopric; manufactures corn-brandy, cotton goods, and cement; and, spite of a shallow harbour, exports much Danish produce. Aalborg is connected with Sundby across the Liimfiord by a remarkable iron bridge. The town was plundered by Wallenstein and the Swedes, impartially in turn during the Thirty Years' War. Pop. 42,000.

Aalbuch, a mountainous region in eastern Württemberg. Hohenstaufen and Hohenrechberg, each with a ruined castle, exceed 2000 feet. See HOHENSTAUFEN.

Aalen, a town in the east of Württemberg, on the Kocher, 46 miles E. of Stuttgart, with metal-ware manufactures; pop. 12,000.

Aalesund, a Norwegian town, 150 miles NE. of Bergen, with an excellent harbour, built on three small islands on the coast of the province of Romsdal. A great centre of the herring-fishery, it was burnt down in 1904. It exports herring, cod-liver oil, and fish products. Pop. 17,000.

Aalia Paakai, a large salt crater-lake of Hawaii, on the island of Oahu, 4 miles from Honolulu. The name is also applied generally.

Aali Pasha, MEHEMET, a Turkish statesman born at Constantinople in 1815, became a clerk in the foreign office, and rose steadily from one diplomatic post to another, at home, Vienna, and elsewhere, till in 1844 he became ambassador at London. His varied experience convinced him of

the absolute necessity of extensive reforms in the government of the Ottoman empire; and with these reforms, under the sultans Abdul-Mejid and Abdul-Aziz, the name of Aali Pasha is identified. He presided at the commission which passed the famous reforming decree of 1856, the *Hatti-Humayun*. At the Congress of Paris he represented the Porte, and maintained its cause with zeal and skill. Grand-vizier more than once, from 1861 till his death (6th September 1871) he held alternately with the like minded Fuad Pasha the most influential posts in the Turkish service.

Aalst, or ALOST, a town in Belgium, the old capital of the province of East Flanders, on the Dender, a navigable tributary of the Scheldt, 19 miles NW. of Brussels by rail. It has trade in hops, corn, besides silk, linen, and woollen manufactures, breweries, distilleries, copper and iron foundries. The church of St Martin, an unfinished edifice, is one of the grandest in Belgium, with a famous painting by Rubens, 'St Roche beseeching our Saviour to stay the Plague of Aalst,' and the mausoleum of Marten, Belgium's first printer (1473). Aalst has also a 13th-century town-hall and a Jesuit college. Pop. 34,000.

Aar (Ger. *Aare*; Fr. *Arve*), next to the Rhine and Rhone the largest river in Switzerland, rises in the glaciers of the Bernese Oberland, forms the Falls of Handeck, 180 feet high, flows through the lakes of Bienn and Thun, and passing the towns of Interlaken, Thun, Berne, Soleure, and Aarau, joins the Rhine above Waldshut after a course of 180 miles. Part of its waters is diverted by canal into the Lake of Bienn; its main tributaries are the Reuss and the Limmat. The Aar contributes more water to the united stream than the Rhine. See GLACIERS.

Aarafat. See ARAFAT.

Aarau, capital of the Swiss canton of Aargau (q.v.), near the foot of the Jura Mountains and on the right bank of the Aar, 40 miles NE. of Berne, and 1100 feet above sea-level. It produces mathematical instruments, cutlery, silks and cottons, leather goods, bells and cannons. The town was for nearly fifty years the home of Zschokke (q.v.), whose monument (1894) is here. Pop. 10,000.

Aard-vark, or CAPE ANT-EATER (*Orycteropus capensis*), one of the Edentata, and the only ant-

Aard-vark.

eater with teeth. It has seven molars on each side above, and six on each side below, with neither incisors nor canine teeth. It is a stout animal,

with long, pig-like snout, tubular mouth, the usual termite catching tongue, large ears, fleshy tail, and short, bristly hair. The limbs are short and very muscular; on the fore feet are four, on the hind five, powerful claws, used in burrowing and in excavating the hills of the white ants (see TERMITES), on which it feeds. It is nocturnal in its habits, and is very inoffensive and timid. When pursued it can burrow itself out of sight in a few minutes, working inwards with such rapidity as to make it almost impossible to dig it out. Its total length is about 5 feet, of which the tail is 1 foot 9 inches. The flesh is edible, but from its food is apt to taste of formic acid. The dwelling of the aard-vark (Dutch, 'earth-hog') is a burrow at a little distance from the surface, and thence it may be observed creeping at dusk. Three species are known—one in South Africa, another in Senegal, a third in South Nubia. See ANT-EATERS.

Aard-wolf ('earth-wolf'; *Proteles cristata*), a South African carnivore, belonging to a sub-family of Hyænidæ. It is fox-like in size and habit, but has longer ears and a less bushy tail. It resembles a hyæna in its sloping back, in its colour, markings, and dorsal mane, but has five toes on the forefeet, and the head is much more pointed and civet-like. The back-teeth are small and simple, and there is no carnassial or special cutting-tooth. The strong, blunt claws are, as usual, non-retractile. It feeds on carrion, white ants, larvæ, &c., but not on living vertebrates. It is timid and nocturnal in its habits, social but quarrelsome in its life, and tolerably swift in its pace, though usually trusting rather to burrowing than to flight. See CARNIVORA, CIVET, HYÆNA.

Aare. See AAR.

Aarestrup, EMIL (1800-56), a Danish poet, born in Copenhagen, who came to his fame as one of the greatest lyrists of Denmark only when his poems were published with an introduction by Brandes.

Aargau (Fr. *Argovie*), the least mountainous canton of Switzerland, on the lower course of the Aar, with the Rhine for its north boundary. Agriculture, dairying, cattle-breeding, the production of wine and fruit, manufactures of cotton, and straw-plaiting are carried on. Excellent iron ore was found in 1919. The canton was taken from the Hapsburgs by the Swiss confederates, was long ruled by the aristocratic party, but in 1831 obtained a liberal constitution. The suppression of eight monasteries in 1841 led to the war of the Sonderbund; and the canton has since been democratic and anti-clerical. German is the dominant tongue. Area, 542 sq. m.; pop. 240,000, more than half Protestants.

Aarhus, second in size of Danish cities, is a seaport on the east coast of Jutland, 68 miles NE. of Fredericia, with a very lively transit trade by sea and by rail. Since 951 the seat of a bishop, it has a fine Gothic cathedral dating from 1201, and two modern churches, one of them Roman Catholic. The harbour was much improved in 1880-90. Grain, hides, tallow, butter, bacon, eggs, cattle, and oysters are exported; while wine, petroleum, salt, sugar, tobacco, manufactured articles, and 'colonial wares' are imported. Pop. (1870) 15,025; (1890) 33,308; (1921) 74,256 (with suburbs, 81,210).

Aarlen. See ARLON.

Aaron, elder brother of Moses and High-priest of Israel for forty years, is much more conspicuous in the priestly narrative of the Pentateuch (q.v.) than in the earlier Jehovistic record. See MOSES, HIGH-PRIEST, PRIEST, LEVI, JEWS.

Aaron's Beard, a popular name for (1) *Saxifraga sarmientosa*, usually grown in hanging pots, from which the long stems or runners droop down, bearing at intervals clumps of roundish,

hairy, somewhat decorative leaves, with flowers resembling those of London Pride; (2) the Great St John's Wort, *Hypericum calycinum*, also called Rose of Sharon, with a prostrate, creeping, shrubby habit, and bearing very large bright-yellow flowers; (3) *Geropogon hirsutus*, one of the Compositæ, related to Tragopogon (Goat's Beard), with purplish capitula; (4) the Ivy-leaved Toadflax, *Linaria cymbalaria* (see TOADFLAX); (5) *Spiræa salicifolia*.

Aaron's Rod, a name given to the Great Mullein (*Verbascum thapsus*; see MULLEIN), and also to the Golden-rod (q.v.).

Aarsens, FRANS VAN (1572-1641), was long the representative of the United Netherlands at the French court, undertook missions to the courts of the Emperor, of Venice, and of England, and at home was a resolute enemy of Barneveldt (q.v.).

Aasen, IVAR (1813-96), born in the district of Søndmøre in Romsdal, Norway, became eminent as the supreme authority on the Norwegian dialects, of which he wrote a grammar and dictionary; and out of them he tried to construct a national Norwegian language, as distinct from the Dano-Norwegian. In this artificial dialect he wrote (otherwise unimportant) plays and poems.

Aath. See ATH.

Abaca, a species of plantain (*Musa textilis*), which yields a valuable fibre, the so-called *Manila Hemp* of commerce. It is a native of the Philippine Isles, where it is known by the native name of Ab'aca, and extensively cultivated; it is like the Banana (q.v.) in habit of growth, the false stem of sheathing leaf-stalks attaining a height of some 20 or 30 feet, with a large crown of leaves. The leaf-stalks are split into long strips, beaten with clubs, hackled, washed, and dried. From the finer fibres, sometimes 15 feet long, exceedingly fine tissues are woven, mainly for native use. The outer and coarser make extremely durable and tenacious cordage, and are largely exported for that purpose, as also for matting. The old ropes are manufactured into very strong wrapping-paper. The value of the fibre—it is the best of all materials for cordage—has led to its being largely adulterated with New Zealand flax and Russian hemp. 'Hemp' is one of the chief products of the Philippines. The comparative merits of Manila hemp and other materials for ropes are discussed at ROPES; see also BANANA, FIBROUS SUBSTANCES.

Abacenum. See SICILY.

Abaco. See BAHAMAS.

Abacus, an instrument sometimes employed in infant-schools to make the elementary operations of arithmetic palatable. It consists of a frame with a number of parallel wires, on which beads or counters are strung, being variously arranged to represent units, tens, &c. By the ancient Romans it was used in practical reckoning, and it is still in use in some parts of Russia, in the Caucasus, Persia, and China. Probably it passed from the Semites to the Aryans, and so on to the Chinese; see CALCULATING MACHINES, NAPIER (JOHN). In architecture, the abacus is a square or oblong level tablet placed above the capital of a Column (q.v.), and supporting the Entablature (q.v.).

Chinese Abacus.

Abadan, or ABBADAN, an island in the Shatt-el-Arab, near its mouth, 8 miles by land, 10½ by river, below Mohammerrah, has large oil-refineries and a flourishing port. The oil comes from oil-fields 150 miles inland.

Abakansk, a town in the very south of Siberia, where the Abakan falls into the Yenisei; pop. 5000.

Abana. See DAMASCUS.

Abancay, chief town of the province of Apurimac in Peru, 65 miles WSW. of Cuzco; pop. 5000.

Abancourt, CHARLES XAVIER JOSEPH D', a French minister during the Revolution, born at Douai in 1758. A nephew of Calonne, and a revolutionist, he advanced rapidly in the army, and became minister of war in June 1792. Two months later he was denounced as a foe to freedom, and was being conveyed to Paris when he was murdered by the mob at Versailles, 9th September 1792.

Abandonment. See DERELICT, SALVAGE, WRECK; DIET (DESERTION OF), NOLLE PROSEQUI; and for the desertion of wife and of children, HUSBAND AND WIFE, PARENT AND CHILD.

Abarbanel, or ABRAVANEL, are two of the many spellings of the name by which Isaac ben Jehudah, Jewish author and statesman, is known. Born at Lisbon in 1437 of a noble Hebrew stock, and distinguished for wealth, learning, and ability, he was employed in affairs of state by Alfonso V. of Portugal; under his successor he was suspected of treason, and obliged to flee (1483). Next he served Ferdinand of Aragon, but shared in the expulsion of the Jews from Spain (1492), and died at Venice in 1508. His works comprise commentaries on the Bible and philosophical treatises, one of them a commentary on the *Moreh* of Maimonides (see the elaborate article in the *Jewish Encyclopedia*, vol. i. 1901). His eldest son, Juda Leon (Leo Hebræus), was a doctor and philosopher, author of *Dialoghi di Amore* (1535), and a friend of Pico Mirandola (q.v.). Isaac's second son, Joseph, practised medicine in Venice and Ferrara; the third son, Samuel (1473-1550), was finance-minister to the Spanish viceroy of Naples.

Abattis (Fr.) is an entrenchment consisting of trees felled and laid side by side; the butt-ends are fixed in the earth, the smaller twigs cut off, and the branches are directed towards the enemy.

Abatteir. See SLAUGHTER-HOUSES.

Abauzit, FIRMIN (1679-1767), was born of Protestant parentage at Uzès in Languedoc, and on the revocation of the Edict of Nantes (1685) was sent by his mother to Geneva, where ere long he distinguished himself by his zeal and various learning. He travelled in Holland and England in 1698, attracting the notice of such men as Bayle and Newton. King William wished to retain him in England; but his affection for his mother recalled him to Geneva. He helped to translate the New Testament into French (1726), and published many theological treatises (collected 1773).

Abb is the form to which, in St Abb's Head, the name of St Ebba or Æbbe has been contracted. Ebba was the daughter of Ethelfrith, king of Northumbria, sister of Kings Oswald and Oswiu, and aunt of Egfrith. Having taken the veil, she founded a monastery at the place called (after her) Ebchester on the Durham Derwent; and was afterwards abbess of a double monastery at or near Coldingham (perhaps actually on the headland of St Abb's), where monks and nuns lived under an abbess. She died about 679. But there seems to have been another Ebba in charge when the monastery was destroyed by the Danes near the end of the 9th century. Long afterwards it was said that this Ebba and her nuns cut off their noses to render themselves hideous in the vikings' eyes, and so save their chastity.

Abbadie, or D'ABBADIE, JACQUES (1654-1727), born at Nay near Pan, of an old Huguenot family, distinguished himself in theology at Saumur and Sedan, and in 1680 was invited by the Elector of Brandenburg to the French congregation in Berlin.

There he remained till 1688, writing on the eucharist and the divinity of Christ. Accompanying Marshal Schomberg to Holland and England, he became pastor of the French Church in the Savoy. He wrote in defence of the revolution of 1688, became a favourite with William III., published a panegyric on Queen Mary, and in 1699 was by the king made Dean of Killaloe, though his English was far from perfect, and he was more zealous in polemical theology and politics than in the functions of his deanery. He was practically starved out, and he died at Marylebone.

ANTOINE THOMSON D'ABBADIE (1810-97) and ARNOULD-MICHEL D'ABBADIE (1815-93) were born in Dublin of French family, but educated in France; both of them became famous as travellers in Abyssinia between 1837 and 1848, becoming again Frenchmen. The elder brother, whose veracity was disputed by Dr Beke (q.v.) but was soon triumphantly established, published on his return a catalogue of Ethiopian MSS., the *Géodésie d'Éthiopie* (1860-73); in 1881 a Dictionary of the Amharic (Amlharic) language; and in 1890 *Géographie de l'Éthiopie*, besides papers or treatises on Ethiopic inscriptions and coins, and articles on Abyssinian subjects. He was of the Legion of Honour, and a member of the Académie des Inscriptions. The younger brother's chief publication was his *Doize Ans dans la Haute-Éthiopie* (1868), which was the official record of the travels and observations of both brothers.

Abbas, the uncle of Mohammed, at first hostile to him, but ultimately the chief promoter of his religion, was born in 566, and died 652. He was the founder of the family of the Abbasides, who ruled as khalifs of Bagdad from 750 till the Mongol conquest in 946, but continued to exercise the spiritual functions of the khalifate, first at Bagdad, and from 1258 in Egypt under the protection of the Mamelukes, till 1517 (see MOHAMMED, KHALIF).—For Abbas the Great of Persia, Abbas II., and their dynasty, see PERSIA.

Abbas I., viceroy of Egypt, was grandson of the famous Mehemet Ali (Mohammed Ali), founder of the dynasty. Born in 1813, he had already taken an active part in his grandfather's Syrian war (1840-41), when in 1848 the death of his uncle, Ibrahim Pasha, called him to the viceregal throne at Cairo. During his brief reign he did much to undo the progress that had been made under Mehemet Ali, and, bigoted and sensual, proved a bitter enemy to foreigners. At the Crimean war he put 15,000 men at the disposal of the Sultan. He was found dead—probably murdered—on the 13th July 1854.—ABBAS II., Khedive of Egypt, was born in 1874, and succeeded his father, the blameless Tewfik (son of the scandalous Ismail, who again was son of Ibrahim), on the throne of Egypt in 1892. Abbas, called Abbas Hilmi or Helmy, was studying at a college in Vienna when his father's death called him, at the age of eighteen, to the responsibilities of government. Tewfik had been a discreet supporter of the British régime, but Abbas not unnaturally fell under the influence of intrigues, who encouraged him to assert himself against foreign domination, and for some years he was a serious obstacle to good government, the reorganisation of Egyptian finance and irrigation, and social reform. He sought to thwart Lord Cromer, and quarrelled with Lord Kitchener, then Sirdar; but the reconquest of the Egyptian Sudan from the Khalifa, the successor of the Mahdi (q.v.), by the reorganised Egyptian army supported by British troops, under Lord Kitchener (1896-98), brought about a working agreement, and in 1899 the Khedive paid a friendly visit to England. When war broke out between Britain and Turkey (November 5, 1914) Abbas Hilmi, who was in Constantinople at the

time, adhered to the Turkish side. He was accordingly deposed, and Egypt was proclaimed a British protectorate under a sultan, Hussein Kâmil, Abbas Hilmi's uncle (December 19, 1914). See EGYPT, and Lord Cromer's *Abbas II.* (1915).

Abbas Efendi. See BÂBI.

Abbas-Mirza, Persian prince and warrior, the favourite son of the Shah Feth-Ali, was born in 1783. Early convinced of the advantages of Western civilisation, he with the help of European officers applied himself to the reform of the army, and led the Persians with great bravery, but with little success, in the wars with Russia in 1811-13 and 1826-28. He died in 1833.

Abbate, NICCOLO DELL' (1512-71), famous as a fresco-painter, was born in Modena, and painted there, at Bologna, and at Fontainebleau, where he died after working on the château for nearly twenty years. There is an altarpiece by him at Dresden.

Abbazia, a health-resort on the bay of Fiume, at the head of the Quarnero gulf of the Adriatic, called the 'Nice of the Adriatic.' It is in what was till 1918-19 the Austrian province of Istria, in a district originally occupied by Slavs (Morlaks), but now thoroughly Italianised. The town, largely consisting of villas and beautiful gardens with luxuriant greenery, is named from an old abbey, now itself transformed into a villa or hydropathic.

Abbé, originally the French name for an abbot, but often used in the general sense of a priest or clergyman. By a concordat between Pope Leo X. and Francis I. (1516), the French king had the right to nominate upwards of 200 *Abbés commendataires*, who, without having any duty to perform, drew a third of the revenues of their monasteries. They were not necessarily clergy, but were expected, unless exempted by a dispensation, to take orders. The hope of obtaining one of those sinecures led multitudes of young men, many of them of noble birth, to enter the clerical career, which, however, seldom went further than taking the inferior orders. They formed a considerable and influential class in society; and an abbé, distinguished by a short violet-coloured robe, was often found as chaplain or tutor in noble households, or engaged in literary work. This class of nominal clergy disappeared at the Revolution. But the word abbé is still applied in a vague and courteous sense to almost any young clergyman, or any one wearing ecclesiastical dress, especially if he is not exercising ecclesiastical functions, but serving as tutor or professor.

Abbe, CLEVELAND (1838-1916), astronomer and meteorologist, was born in New York city, and educated there, at Ann Arbor, and at Cambridge (Mass.) After some years at Pulkova in Russia, he established at Cincinnati (1869) a system of daily weather forecasts which he was summoned by the government to continue at Washington. He also initiated the American system of standard time and hourly meridians; was professor of Meteorology at George Washington University, 1885-1910; taught his science at the Johns Hopkins University in Baltimore; was meteorologist in the U.S. Weather Bureau from 1891; wrote several meteorological treatises and edited various weather-periodicals.

Abbeokuta, or ABEOKUTA, a city, or rather collection of small towns or villages, capital of a territory in the Yoruba country, in the south-west of the British protectorate of Nigeria. It is about 80 miles N. of Lagos, and is situated 560 feet above the sea-level, on an undulating plain. The city is surrounded by a high wall of hardened mud, from 18 to 20 miles in circumference; the town proper measures 4 miles by 2. There is trade in palm-oil and European goods. Pop. 60,000.

Abness. See ABBOT, MONACHISM, NUN.

Abbeville, a prosperous manufacturing town of France, in the department of Somme, stands on the river Somme, 12 miles from its mouth, and 49 miles south of Boulogne. It is built partly on an island, partly on the banks of the river. The west front of the church of St Wolfram, commenced in the reign of Louis XII., is a splendid example of the Flamboyant style, with noble portals and covered with rich tracery; Ruskin called Abbeville 'the preface and interpretation of Rouen.' The museum has a rich collection of antiquities. Abbeville manufactures woollens and linens, hemp goods, sacking, and sugar; there is some shipbuilding, and a brisk trade in grain and local manufactures. Near Abbeville were found, by Boucher de Perthes (q.v.) in 1841, the flint implements, associated with the remains of the mammoth and rhinoceros, which have such an important bearing on the controversy as to the antiquity of man, and in this work are discussed at FLINT IMPLEMENTS, MAN, and STONE AGE. The treaty by which Henry III. surrendered to the French king Normandy, Touraine, Maine, and Anjou was negotiated at Paris, but is named from Abbeville, where Henry met Louis IX. in 1259. Another treaty was actually negotiated in 1527 at Abbeville, by Wolsey, between Henry VIII. and Francis I. Pop. 20,000.

Abbey. See ABBOT, MONASTERY, MONACHISM, SANCTUARY.

Abbey, EDWIN AUSTIN, painter, was born at Philadelphia, 1st April 1852, and studied and practised drawing and painting at Philadelphia and New York, becoming known first as a book-illustrator in black-and-white, and a painter in water-colours. Having come to England in 1883, he won recognition as a powerful painter, specially distinguished for canvases dealing with Shakespearean subjects, such as Richard III., Hamlet, and Lear's Daughters. He attained the dignity of A.R.A. in 1896, and of R.A. in 1898, painted the historic record of Edward VII.'s coronation in 1902, and died 1st August 1911. See Life by E. V. Lucas (1921).

Abbot, a word derived from the Aramaic *abba*, 'father,' through the Latinised form *abbas*, was at first used of reverend persons, especially aged monks, but was ere long reserved, as a title of dignity, for the head of a monastery or abbey. Until the beginning of the 10th century, the head of every monastery was called abbot; but after the reformation of the order of Benedictines, monasteries arose that were dependent upon the mother-monastery of Clugny and without abbots, being presided over by *priors* or *pro-abbates*. Many of the orders founded after the 10th century rejected the title, and called their superior *praepositus* or *prior* (as the Carthusians, Dominicans, Carmelites, Augustinians), *custos* or *guardian* (as the Franciscans), *major* or *rector*. The relation of the abbot to his order on the one hand and to his monks on the other varied greatly in the different orders; the Benedictine abbot was wholly independent, while a supreme council at Clairvaux might interfere in the management of all the Cistercian communities. But the abbot was always entitled and bound to enforce the observance of the rules of his order, to administer the goods of the monastery, and to exact unconditional obedience from his monks. Since the 6th century, at least in the Eastern Church, abbots have generally held clerical orders, but at first, and in the Western Church even down to the 11th century, they were not necessarily priests. By the second Nicene Council (787), abbots were empowered to consecrate monks for the lower sacred orders; but they remained in subordination under their diocesan bishops until the 11th century. As abbeys became wealthy, abbots increased in power and influence; many

received episcopal titles; and all were ranked as prelates of the church next to the bishops, and had the right of voting in church-councils. Even abbesses contended for the same honour and privileges, but without success. In the 8th and 9th centuries, abbeys began to be granted by the kings to laymen as rewards for military service; professedly they were granted only temporarily *in commendam*. Occasionally an abbey voluntarily elected a powerful noble as its head for the sake of his protection, the titular abbot enjoying the revenues, but interfering little with the management of his abbey. In the 10th century, many of the chief abbeys in Christendom were under lay-abbots (*Abbatēs milites*, or *Abba-comites*), while subordinate deans or priors had the spiritual oversight. The members of the royal household received grants of abbeys as their maintenance, and the king kept the richest for himself. Sometimes convents of nuns were granted to men, and monasteries to women of rank. Gradually it became not unusual for one man, lay or ecclesiastic, to hold two or more abbeys at once; but these and the like abuses were, in a great measure, reformed during the 10th century.

The abbot was usually under the jurisdiction of his diocesan bishop; but there were many cases of exempted abbots, who acknowledged no superior but the pope. They then exercised a quasi-episcopal authority over what was practically their diocese, and enjoyed the right to wear the episcopal insignia—an honour often granted without exemption from the authority of the bishop, but conveying the rank of *mitred abbot*. In England there were twenty-four mitred abbots, who, however, sat in parliament simply as holding baronies under the crown. On the Continent, not a few abbots had princely titles and privileges, voting in the national councils. The election of an abbot belongs, as a rule, to the chapter or assembly of the monks, and is afterwards confirmed by the pope or by the bishop, according as the monastery is independent or under episcopal jurisdiction. But from early times, the pope claimed the right of conferring many abbeys, and the concordat of 1516 gave a similar privilege to the king of France. Popes as well as princes frequently abused this recognised or usurped power by giving abbeys to members of the secular clergy, who were accordingly not bound by monastic rules (see *ABBÉ*). Such abbots were *secular abbots*, while those subject to the rule (*regula*) of a monastic order were *regular abbots*. In countries which embraced the Reformation, the possessions of abbeys were mostly confiscated by the crown; but in Hanover, Brunswick, and Württemberg several monasteries and convents were retained as educational establishments, the heads of which retained the title of abbot or abbess. In the Greek Church, the superiors of convents are called *Hegumeni* or *Mandrites*, and general abbots *Archimandrites*. Amongst Copts and Syrians, *abba* is a title given to bishops or patriarchs. The head of the Abyssinian Church is called *abbuna* ('our father'). An abbess, the superior of a religious community of women, corresponded in rank and authority to an abbot, except in not being allowed to exercise the spiritual functions of the priesthood—such as preaching or confession. See *MONACHISM*, *NUN*.

Abbot, EZRA, scholar and biblical critic, was born in Jackson, Maine, 28th April 1819; studied at Bowdoin College; in 1856 became assistant-librarian at Harvard University; and in 1872 was chosen professor of Biblical Criticism in the Harvard divinity school. He wrote much for the periodicals, helped in preparing the American edition of Smith's *Dictionary of the Bible*, assisted Dr Caspar René Gregory in the prolegomena to

the *editio octava major* of Tischendorf's Greek New Testament, and was a member of the New Testament Revision Company. Among his works are *New Discussions of the Trinity, Literature of the Doctrine of a Future Life, Critical Essays* (1888), and *The Authorship of the Fourth Gospel* (1880; extended 1888). LL.D. of Yale, and D.D. of Harvard, he died 21st March 1884.

Abbot, GEORGE, Archbishop of Canterbury, was the son of a Guildford cloth-worker, and was born 29th October 1562. In his seventeenth year he entered Balliol College, Oxford, where he obtained a fellowship (1583); and through Lord Buckhurst's influence he rose to be Master of University College (1597), Dean of Winchester (1600), and thrice Vice-chancellor of Oxford University (1600-5). To a new patron, the Earl of Dunbar, with whom he visited Scotland (1608), he owed his promotion to the sees of Lichfield (1609), of London (1610), and finally of Canterbury (1611). A sincere but narrow-minded Calvinist, he was equally opposed to Catholics and to heretics, Arian or Arminian. He fined two recusants, he burnt two Arians, he consented that a clergyman should be put to the torture; but, withal, he was charitable, and far less obsequious to the kingly will than most of his compeers. His closing years were clouded by an accident, the shooting of a gamekeeper (1621); and during the last six he was almost superseded by his great adversary, Laud. He died at Croydon, 4th August 1633, and was buried at Guildford, where in 1619 he had founded a hospital.—His brother, ROBERT (1560-1617), from 1615 Bishop of Salisbury, was a learned theologian, and author of several controversial treatises.

Abbot, CHARLES. See *COLCHESTER (LORD)*.

Abbotsford, the seat of Sir Walter Scott, stands on the south bank of the Tweed, a little above its confluence with Gala Water, and 2 miles W. of Melrose. Before it became, in 1811, Sir Walter's property, its site was the small farm of 'Clarty Hole'; the new name recalled the days when Melrose abbots fished the Tweed at this spot. Here he built a small villa, now the western wing; and in 1817-24 he added the other portions of the building, combining in it some of the features (and even actual remains) of those ancient works of Scottish architecture which he most venerated. The result was that picturesque irregular pile, that 'romance in stone and lime,' which is further a veritable museum of historical curios and personal relics of Scott. Through Mrs Lockhart and her daughter (Mrs Hope Scott) it passed to Scott's great-granddaughter, the Hon. Mrs Maxwell-Scott (1852-1920).

Abbott, CHARLES. See *TENTERDEN (LORD)*.

Abbott, EDWIN ABBOTT, theologian and philologist, was born in London, 20th December 1838. After a brilliant career at St John's, Cambridge, he obtained a fellowship, was master at King Edward's School, Birmingham, and at Clifton College, and from 1865 to 1889 was headmaster of the City of London School. His sermons gave him a place in the front rank of the more liberal theologians within the English Church; his view of Christianity he stated in *Through Nature to Christ* (1877). He is admitted to be the author of *Philochristus* and *Onesimus*, two anonymously published romances of the first age of the church, and of *The Kernel and the Husk* (1887), an amplification of the same view of Christianity. *Philomythus* (1891) and the articles on the gospels in the *Encyclopædia Britannica* (1879) and *Encyclopædia Biblica* were also theologically 'advanced.' His *Shakespearean Grammar* (1870) was followed by works on Bacon, Newman, Becket; on New Testament Greek (*Johannine Grammar*) and criticism, *Silvanus the Christian*, and *The Fourfold Gospel* (1913 et seq.).

Abbott, JACOB (1803-79), born at Hallowell, Maine, U.S., studied at Bowdoin and Andover, was professor of mathematics in Amherst College (1825-29), became a Congregational pastor, but devoted most of his life to school work and educational literature. In 1838 he began writing simple and popular works, mainly for the young; the 'memorial edition' of the best known, *The Young Christian*, contained a life by his son. He published over two hundred volumes, largely didactic fiction and somewhat superficial history, amongst which are 'The Franconia Stories' (10 vols.), 'Histories for the Young' (19 vols.), 'Marco Paul's Adventures' (6 vols.), 'Harper's Story Books' (36 vols.), 'The Rollo Books' (36 vols.), 'American Histories for Youth' (8 vols.).—**LYMAN ABBOTT** (1835-1922), his son, was born at Roxbury (now in Boston); studied and practised law; but subsequently became a Congregational minister in New York and elsewhere, becoming Ward Beecher's successor in Brooklyn (1888-99). He published a religious dictionary, a New Testament commentary, books on evolution and Christianity and on social problems, the life of Ward Beecher, *Reminiscences*, and (with his brother) novels. From 1893 he was editor-in-chief of *The Outlook*.—**JOHN STEPHENS CABOT ABBOTT** (1805-77), Jacob's brother, was born at Brunswick, Maine, studied at Bowdoin and Andover, and was minister in Worcester and Roxbury. He wrote histories of Napoleon Bonaparte (1855, readable, but extravagantly panegyric), of the French Revolution, Marie Antoinette, Josephine, Napoleon III., the American Civil War, &c.

Abbottabad, a town and cantonment, 65 miles NNE. of Rawal Pindi, is headquarters of the Hazara district, North-west Frontier Province, and was named after Sir James Abbott (1807-96), who organised the country after annexation; pop. 11,500.

Abbreviations, contrivances in writing for saving time and space, in which the initial syllable, initial or other letters, or arbitrary signs are made to do duty for whole words and phrases. In ancient inscriptions, in Greek and Roman MSS., and in mediæval documents, such saving of space was extremely important, and abbreviation and contraction were carried so far that to decipher them special training is necessary; see **PALÆOGRAPHY**, **INSCRIPTIONS**. In the earliest times, when uncial or lapidary characters were in use, initials were often made to serve, like M for *Marcus*, F for *filius*. Signs of abbreviation, and characters representing double consonants, syllables, and words, became common after the invention of the small Greek and Roman letters. From the MSS. they passed into early printed texts, and only within the last century have they disappeared from Greek texts. The middle ages inherited many Roman contractions in inscriptions, MSS. and legal documents, and thence they survived into comparatively modern use. An act of George II. forbade abbreviations in legal documents. Shorthand (q.v.) has an elaborate system of its own. Here only abbreviations used in current English literature are given. The most obvious are omitted. For chemical symbols, see **ATOMIC THEORY**, **CHEMISTRY**.

Abd-el-Kader ('servant of God'), properly Sidi-el-Hadji-Abd-el-Kader-Uled-Mahiddin, the famous hero in the great Algerian struggle with the French, was born at Mascara in 1807. A scion of a priestly house that traced its pedigree to the califs of the lineage of Fatima, he was carefully educated, and early succeeded to the high influence held by his father among his countrymen. His public career began at the time of the conquest of Algiers by the French. No sooner was the power of the Turks broken than the Arab tribes of the province of Oran elected him as their emir. He thus found himself the leader of the combined tribes in their attempt to check the growing power of France in Northern Africa, and began that long struggle with the French, which he waged with such marvellous perseverance and strategic skill, from 1832 to 1847. Often defeated, he appeared soon after at the head of new troops, and baffled the enemy by his marvellous rapidity. In 1834 he compelled General Desmichels to recognise his authority in a treaty, and meantime his influence spread widely among the tribes of the interior. Hostilities soon broke out again, and in June (1835) he inflicted a severe defeat on a large French army at Makta. Spite, however, of his heroism, he was crushed by overpowering force, and compelled, after a protracted struggle, to take refuge in Morocco. Here he succeeded in getting up a sort of crusade against the enemies of Islam; but Bugeaud's decisive victory at Isly in 1844 obliged the sultan of Morocco to give up the cause of Abd-el-Kader, though he could not prevent his wailike subjects from giving sympathy and some support to the brave champion of their faith. His own security soon obliged the sultan to oppose him actively, and at length Abd-el-Kader was forced, after a daring but unsuccessful attack on the Moorish camp, to retreat into the territory of Algeria, where he had to surrender to General Lamoricière, December 22, 1847. He was sent with his family to France, where he lived in honourable captivity, until liberated in 1852 by Louis Napoleon. He afterwards resided successively at Broussa in Asia Minor, at Constantinople, and finally at Damascus. Enjoying a French pension of 100,000 francs, he spent his leisure in writing a religious and philosophical work, translated in 1858 under the title *Rappel à l'Intelligent. Avis à l'Indifférent*. He was of great service to the cause of humanity during the Syrian massacres of 1860, and for this was decorated by Napoleon III. with the Grand Cross of the Legion of Honour. In 1865 he visited Paris and England, and he was present at the Paris Exhibition in 1867. He died at Damascus, 28th May 1883.

The Life of Abd-el-Kader, by C. A. Churchill (1867), said to be 'written from his own dictation, and compiled from other authentic sources,' savours somewhat too much of panegyric. There are also several French lives—such, for example, as that of Laménare (1848), that of Bellemare (1863), and that of Pichon (1899).

Abdera, a town which stood on the south coast of ancient Thracia, to the east of the river Nestus. Colonised by the inhabitants of Teos in 541 B.C., it afterwards came under the power of Athens, and was a free town under the Romans. Although the birthplace of such distinguished men as the philosophers Democritus, Protagoras, Anaxarchus, and the historian Hecateus, Abdera was the Gotham of antiquity, and 'Abderite' was a proverbial name for a simpleton.

Abd-er-Rahman, or ABD-AL-RAHMAN KHAN, Amir of Afghanistan, was the grandson of Dost Mohammed (see AFGHANISTAN), and after his grandfather's death (1863) for a time supported successfully the claims of his father, Afzul, against his uncle, Shere Ali. When after 1868 Shere Ali

was triumphant over all rivals, Abd-er-Rahman took refuge in Russian Turkestan, and became practically a Russian pensioner; till, on the death of Shere Ali, he succeeded in overthrowing his son, Yakub Khan, and from 1880 was fully recognised as Amir. Contrary to expectation, he was in no wise pro-Russian, but eminently friendly to Britain, like his grandfather. He showed masterly skill and energy in consolidating his power, extending his frontiers amongst the hill-tribes, still more savage than his own Afghans, and in promoting such European arts and manufactures (notably rifles) as seemed likely to conduce to his own well-being and the security of the state. His additional territory was secured to him by treaties with Britain, and he was made K.C.B. and G.C.S.I. A life of him was written by Mr Stephen Wheeler in 1895; and Mr J. A. Gray, who was surgeon and painter-in-ordinary to the Amir (and official taster of spirits distilled in the country), wrote a vivacious account of life *At the Court of the Amir* (1895; new ed. 1901). At his death in 1901 he was succeeded by his son, Habibulla Khan. See also ABD-UR-RAHMAN.

Abdication, the resignation of an office by a ruler or sovereign, is rarely due to preference for a private station, is generally the result of vexation and disappointment, but is sometimes caused by a father's wish to relieve his son and his dynasty from the unpopularity of his own failures. It was from being wearied with dominion that Diocletian abdicated (305 A.D.). Christina of Sweden retired from the throne (1654) out of preference for the freedom of private life, but wished still to exercise the rights of a sovereign. Charles V. laid down the crown (1556) chiefly from ill-health, but partly, too, because his great schemes had failed. Philip V. of Spain did so (1724) in a fit of melancholy, but resumed it on the death of his son. Louis Bonaparte resigned the crown of Holland (1810) because he would not consent to treat that country as a province of France. Charles-Emmanuel of Sardinia retired from the throne in 1802, not finding himself equal to the crisis; and the same was the case with Victor-Emmanuel in 1821. William I. of the Netherlands resigned (1840) as his policy had become impossible from the turn of affairs in Belgium. Foreign force compelled the abdication of Augustus of Poland (1704), and later, that of Stanislaus Leszczynski (1735) and of Poniatowski (1795); as well as that of Charles IV. of Spain (1808), and of Napoleon (1814 and 1815). Insurrections have been a frequent cause of abdications. In England we have the compulsory abdication of Richard II. (1399); in Scotland that of Mary at Lochleven (1567); and the early history of the Scandinavian kingdoms furnishes many instances. Modern times have seen Charles X. (1830) and Louis-Philippe (1848) retire before the storm of revolution, without the conditions they made being regarded; have seen, too, the abdication of Ferdinand of Austria (1848), of Louis of Bavaria (1848), of Amadeus of Spain (1873), of Prince Alexander of Bulgaria (1886), of Manoel of Portugal (1910), of the Emperor of China (1912), of Constantine of Greece (1917; regained throne 1920, finally lost 1922), and of George II. of Greece (1924). The revolutions of 1917-18 brought about the abdication of the Russian, Austrian, and German emperors, and the abdication or deposition of the German federal princes, and of other sovereigns.

In some countries the king can abdicate whenever he pleases; but in England, the constitutional relation between the crown and the nation being of the nature of a contract, the king or queen, it is considered, cannot abdicate without the consent of parliament. It is, however, said that the king does abdicate, or, to speak perhaps more correctly,

an abdication may be presumed and acted on by the people, if his conduct politically and overtly is inconsistent with, and subversive of, the system of constitutional government, of which the qualified monarchy of his office forms part. Thus, in the case of James II., it was disputed whether the king had 'abdicated' or 'deserted.' At the conference between the two Houses of Parliament previous to the passing of the statute which settled the crown on William III., it would appear that the word 'abdicated' was advisedly used instead of 'deserted'—the meaning, it is presumed, being that James had not only deserted his office, but that by his acts and deeds, of which the said desertion formed part, he had, in view of the constitution, ceased to have right to the throne. From this it may be inferred that abdication was considered to have a twofold political signification, involving maladministration as well as desertion. The Scotch Convention, however, more vigorously and distinctly resolved that King James 'had forfeited the crown, and the throne was become vacant.'

Abdomen. The trunk of the human body is divided by the diaphragm into two cavities—the upper being the thorax or chest, and the lower, the abdomen or belly. Both the cavity and the viscera

Organs of the Chest and Abdomen

A, B, lungs; C, heart; OO, diaphragm; P, liver; Q, gall bladder; R, spleen; S, stomach; TUV, colon; W, W, small intestines.

it contains are included in the term abdomen. It is subdivided into two parts, the *abdomen proper*, and the *pelvis*, or basin. The former contains the liver, pancreas, spleen, and kidneys, as well as the stomach, small intestine, and large intestine or colon; the latter, the lowest part of the cavity, contains the lower bowel or rectum, the urinary bladder, and internal organs of generation. The abdomen is lined by a serous membrane, the peritoneum, which covers the free surfaces of the viscera, allowing them a certain range of movement, but keeping them in their proper relations to each other. For the purpose of making accurate reference to the position of the contained organs, the abdomen

proper is artificially divided externally by two horizontal planes into three principal *zones*—the upper, the middle, and the lower. These are again subdivided by two vertical planes into nine areas—the three lateral divisions upon either side being named from above downwards, the hypochondriac, lumbar, and iliac regions respectively; while the names epigastric, umbilical, and hypogastric, are applied from above downwards to the three mesial areas. See the article DIGESTION; also LIVER, BLADDER, &c.—In entomology, the abdomen is the posterior of the three parts into which the body of an insect is divided. See INSECT.

Abduction. In the older systems of law, abduction meant the unlawful taking away of a free person, or of a slave belonging to another. Thus, the buying of a free person was punishable by the criminal law of Rome under the name of *plagium*, which is still used in Scotland for the theft of children. Substantially, however, in modern times, abduction, except in the special cases of voters and witnesses, is confined to the case of women and children. In England, *Kidnapping* (q.v.) includes the theft of any person, but is more properly applied to the taking away beyond the seas—whereby the person loses the protection of his own laws. For this the technical term in Scotland is abduction. In England, abduction technically means the taking away of a woman either against her own will, or (in the case of a woman under the age of 21) against the will of her parents or guardians. The common forms of the crime are defined in the Criminal Law Consolidation Act, 1861. Where the woman is taken by force or fraud with a view to marriage or seduction, the heavy penalty of fourteen years' penal servitude may be inflicted, with the forfeiture of the husband's property rights, if marriage has taken place. The mere abduction of an unmarried girl under 16 from her parents or guardians, is punishable by two years' imprisonment. Under the Criminal Law Amendment Acts, 1885 and 1912—applicable to both England and Scotland—such taking of a girl under 18 with a view to seduction meets with the same punishment, provided there was no reason to suppose the girl was above 18. The procuration or attempted procuration of a girl under 21 for the purpose of unlawful connection, and the procuration or attempted procuration of any woman or girl, of any age, to become a prostitute, are offences punishable with two years' imprisonment. Under the Criminal Law Amendment Act, 1912, a male person convicted of such procuration may, in addition to imprisonment, be sentenced to be once privately whipped, the number of strokes and the instrument of whipping being specified in the sentence of the court. The abduction of children under 14 is technically known in England as child-stealing, and is punishable by penal servitude. The mother of a child, or the father of a bastard, is in no case chargeable with the offence. Generally the offence of abduction is more often committed by decoying and fraudulent arts than by force. In Scotland the *plagium* is more comprehensive than the English child-stealing, as it applies to all cases of children under puberty, whatever the motive may be.

In the United States abduction is the taking and carrying away of a child, a ward, a wife, &c. by fraud, persuasion, or open violence. Every one who takes away any female under the age of 18 years from her father, mother, guardian, or other person having the legal charge of her person, without her consent for the purpose of prostitution, is guilty of a felony. The gist of the offence is the enticing and carrying away. In abduction for the purpose of marriage, it is not necessary to use physical force or violence.

Abdul-Aziz, the thirty-second sultan of the

Ottoman Turks, was born 9th February 1830, the younger son of Sultan Mahmud II. (see TURKEY), and succeeded his brother, Abdul-Mejid, in 1861. At first he showed himself liberal-minded and open to Western ideas; but the promise of economy and reform was illusory, and ere long the sultan began to spend vast sums on his army, the embellishment of his capital, on hunting, and on costly journeys. Spite of this, reforms were long hoped for, especially after his visit to western Europe in 1867. His government had great difficulties to contend with in the Cretan insurrection, the struggle of Rumania and Serbia for full autonomy, and Russian intrigues; and he plunged ever into deeper financial difficulties, while stupid misgovernment led, in 1875, to risings in Bosnia, Herzegovina, and Bulgaria. A conspiracy forced him to abdicate the throne, 30th May 1876; and four days later he was found dead, almost certainly by foul play.

Abdul Bahá, SIR, or ABBAS EFENDI (1844-1921), son of Bahá'U'lláh, and his successor as leader of the Bahai religious movement. See BAHÍ.

Abdul-Hamid I., sultan of Turkey in 1773-1789; see TURKEY.—**ABDUL-HAMID II.**, second son of Sultan Abdul-Mejid, born 22d September 1842, succeeded in 1876, on the deposition of his brother, Murad V. The chief events of his reign were the unsuccessful war with Russia (1877-78); the Armenian atrocities (1894-96), which earned him the title of the 'Great Assassin'; the rising in Crete (1895-96); the successful war with Greece (1897); and troubles and reforms in Macedonia (1902-3). Deposed in 1909, he was succeeded by his younger brother, Mohammed V., and died 10th February 1918. See Life by Sir Edwin Pears (1917), and the article TURKEY.

Abdul-Latif (1162-1231), a great Arabian writer, was born at Bagdad and educated mainly at Damascus, and having settled in Egypt for some years, taught medicine and philosophy at Cairo; he afterwards lectured at Damascus. His numerous works were mainly on medicine; but his best-known book is a valuable descriptive work on *Egypt*, translated into Latin by White (Oxford, 1800), and into French by De Sacy (1810).

Abdul-Mejid, the Grand Sultan, was born 23d April 1823, and succeeded his father, Mahmud II., in 1839. The Turkish empire was then in a very dangerous position. Its army had been defeated and dispersed by the Egyptians in the battle of Nisib, and there was nothing to hinder the victorious Ibrahim Pasha from advancing on Constantinople, where a large party were favourable to the Egyptian power under Mehemet Ali. Had it not been for the intervention of the Christian powers, the house of Othman was lost. The treaty of 1840, from which France kept aloof, obliged Mehemet Ali to submit; and the treaty of 1841, to which France subsequently adhered, settled securely the future dependent relation of Egypt to Turkey. The sultan, on the advice of Reshid Pasha, proceeded in the path of reform begun by his father, and by the famous *hatti-sherif* of November 3, 1839, promised equal protection to all his subjects irrespective of their creed. Numerous reforms followed, but many of his decrees had but little effect, as the sultan lacked energy both of body and mind. He acted a chivalrous part in 1850 in refusing, at the risk of losing his throne, to give up Kossuth and the other political refugees to the menaces of Russia and Austria, and he had a specially difficult part to play during the war with Russia (1854-56), the diplomatic negotiations, and the Hatti-Humáyin (see STRATFORD DE REDCLIFFE). From this time the sultan sunk into unworthy indolence, and allowed public affairs to drift into financial ruin. He died 25th June 1861.

Abd-ur-Rahman, sultan of Fez and Morocco, born 1778, succeeded his uncle in 1823. His first four years of rule were occupied in quelling insurrections. Next, some danger to the state of Morocco was threatened by the refusal of Austria to pay the tribute for safety against pirates; but the sultan wisely adjusted the dispute by relinquishing this sort of blackmail, formerly levied by Morocco on European ships in the Mediterranean. The religious war under Abd-el-Kader against the French in Algeria involved the sultan in its movements. The piratical habits of his subjects brought him to the brink of war with more than one European state. He died in 1859.—The same name, also spelt Abd-al-Rahman and Abderahman, is the name of the leader of the Saracens defeated at Tours in 732 by Charles Martel (q.v.), and of the first Ommiad khalif of Cordova (755-788). See KHALIF, SPAIN; also ABD-ER-RAHMAN, AFGHANISTAN.

Abecedarians, a small sect among the Anabaptists in Germany in the 16th century, noted for their dislike to learning. They thought it best not even to learn to read, as a knowledge of the Scriptures was all that was necessary, and this was communicated by the Holy Spirit direct to the believer without the medium of the written word.

À Becket, THOMAS. See BECKET.

A Beckett, GILBERT ABBOTT (1811-56), born in London and educated at Westminster, was called to the bar in 1841, and in 1849 became a metropolitan police-magistrate. Besides writing for *Punch*, the *Times*, and many serials, he was author of *The Quixotology of the British Drama*, and is specially remembered as the inventor of the 'comic' *Blackstone* and the 'comic' *Histories of England and Rome*—the first illustrated by Cruikshank, the last two by Leech.—One son, Gilbert (1837-91), was a playwright; another, Sir Albert (1840-1904), was accountant-general in the War Office; a third, Arthur William (born 1844, died 1909), was successively or contemporaneously playwright, novelist, barrister, journalist, and editor.

Abel, second son of Adam, slain by his elder brother Cain; see ADAM, CAIN. The Christian Church has, in all ages, regarded Abel as a type of innocence and faith; and the Bible record was supplemented by the Rabbins and by the Koran.

Abel, SIR FREDERICK AUGUSTUS, a well-known chemist, was born in London in 1827. He chiefly devoted himself to the science of explosives, expounding his discoveries and investigations in *Gun-cotton* (1866), *The Modern History of Gunpowder*, *On Explosive Agents*, *Researches in Explosives*, and *Electricity applied to Explosive Purposes* (1884). He further wrote, in conjunction with Colonel Bloxam, a *Handbook of Chemistry*. Some of his researches are mentioned in the articles GUN-COTTON and GUNPOWDER. He held important posts as chemist to the War Department and Ordnance Committees, and was made C.B. in 1877, K.C.B. and D.C.L. in 1883, and a baronet in 1893. Appointed secretary to the Imperial Institute in 1887, he was president of the British Association in 1890. He died 6th September 1902.

Abel, KARL FRIEDRICH, a German musician, born at Koethen in 1725. He was a pupil of Sebastian Bach, and in 1758 he came to England, where ere long he was appointed chamber-musician to the queen of George III. A composer for piano and strings (himself last of the great players on the viola-gamba), he died in London, 22d January 1787.

Abel, NIELS HENRIK, one of the ablest and acutest mathematicians of modern times, was born at Findö, Christiansand, 5th August 1802. He became a lecturer at the university of Christiania.

and the school of engineering there. His works deal mainly with the theory of elliptical functions, which his discoveries greatly enriched. He died 6th April 1829. See *Life* by Bjerknes (Fr. trans. 1885).

Abelard (Fr. *Abélard* or *Abailard*; Lat. *Abelardus*), PETER, the keenest thinker and boldest theologian of the 12th century, was born at Pallet or Palais, near Nantes, in 1079. Resigning his prospects as eldest son of a noble Breton house, he chose the career of a scholar. During the wanderings of his studenthood, he heard Roscellin, the champion of extreme Nominalism (q.v.), and was a pupil of William of Champeaux, one of the foremost of the Realist teachers. His singular gifts as a dialectician soon enabled him to encounter his master in debate, and he speedily met with brilliant success as a scholastic lecturer. In or about 1115 he became William's successor in the school of Notre-Dame; and for a few years he enjoyed a repute and influence such as few teachers have ever had. Amongst the pupils his teaching helped to mould were not a few of the greatest men of the age: Pope Celestine II., Peter Lombard, Beiergar, and Arnold of Brescia. But Abelard's fall from prosperity and power was sudden and rapid. Within the precincts of Notre-Dame lived Héloïse, the niece of the canon Fulbert, then seventeen years of age, and already remarkable for her beauty and accomplishments. She soon kindled in the breast of Abelard, then thirty-eight years old, an overwhelming passion, which was returned by Héloïse with no less fervour. By the uncle's choice, Abelard became Héloïse's tutor and an inmate of the same house, and the lovers were happy together until Abelard's glowing love songs reached the ears of the canon. He sought to separate the lovers; but it was too late. They fled together to Brittany, where Héloïse bore a son, and was privately married to Abelard with the consent of her uncle. Not long after, Héloïse returned to Fulbert's house, and with singular self-devotion denied the marriage, that her love might be no hindrance to Abelard's advancement in the church. When shortly after Héloïse fled to the convent of Argenteuil, Fulbert, enraged at her husband's connivance, caused him to be brutally mutilated, so that he might be made canonically incapable of ecclesiastical preferment. In deep humiliation, Abelard entered the abbey of St Denis as monk; Héloïse took the veil at Argenteuil. Ere long a synod at Soissons (1121) condemned his teaching on the Trinity as heretical, and ordered him to be confined for a time.

In the hermit's hut at Nogent-sur-Seine, to which he retired, Abelard was soon again besieged by importunate disciples; the hermitage became a monastic school known as Paraclete, which, when Abelard was invited to become abbot of St Gildas-de-Rhuys in Brittany, was given to Héloïse and a sisterhood under her care. In his abbey Abelard maintained for ten years a struggle with disorderly and unfriendly monks, and at last fled from the hopeless task. Freed from his charge by the pope, he now devoted himself to the revision of all his works. When he ventured again to appear in public as a teacher, his theological adversaries, headed by Bernard of Clairvaux (q.v.), accused him of numerous heresies, of which he was found guilty by a council at Sens and by the pope. On his way to Rome to defend himself he died, reconciled ere death to his opponents, and absolved by the pope, at the priory of St Marcel, near Chalon, 21st April 1142. His remains were given into the keeping of Héloïse, whose own were twenty years afterwards laid beside them. From Paraclete, the ashes of both were taken to Paris in 1800, and in 1817 were buried in one sepulchre at Père la Chaise, where still they lie.—Abelard

did more than any other to develop and fix that method of joint philosophising and theologising which was characteristic of the great Scholastics (q.v.); it was Abelard who made Aristotle the almost exclusive basis of theological dialectics. In the question of the universals (see NOMINALISM), he took a place between the extreme Nominalists and the thoroughgoing Realists. In opposition not merely to the unreasoning devotion of Bernard and the mystics, but as against the systematic dogmatism of Anselm, he taught that only that faith is well assured which is founded on reason. 'Understand that thou mayest believe' was his motto, not 'Believe that thou mayest understand.' His ethical system he set down in the work *Nosce teipsum*. *Sac et Non* is a curious collection of direct contradictions on important points gathered from the Fathers.

See monographs by Rémusat (Paris, 1845), Carrière (Giessen, 1853), Wilkens (Göttingen, 1855), Sauerland (Frankf. 1879), Deutsch (Leip. 1883), and Compayré (trans. 1893). The story of his life forms the subject of a remarkable drama by Rémusat; and the still extant correspondence between Abelard and Héloïse suggested to Pope his *Epistle of Heloise to Abelard*. The best collective edition of Abelard's works is by Cousin (2 vols. 1849-1859). And see *Peter Abelard*, by Joseph McCabe (1901).

Abelmoschus. See HIBISCUS.

Abencerrages, a noble Moorish family which came to Spain in the 8th century, and were named from Jusuf ben Serragh. Their struggles with the family of the Zegrís, and tragical destruction in the royal palace of the Alhambra, in Granada, in the time of Abu Hassan (1466-84), the last but one of the kings of Granada, furnish the materials for the legend, probably unhistorical, found in Perez de Hita's *Historia de las Guerras Civiles de Granada* (1694). On this Chateaubriand based his romance, *Les Aventures du dernier des Abencerrages*, which furnished Cherubini with the text of an opera.

Aben-Ezra, properly Abraham-Ben-Meir-Ben-Esra, born 1093 at Toledo, died 1168 in Rome, was one of the most learned Jews of his time, distinguished for his knowledge of philosophy, mathematics, astronomy, and medicine. He visited France, Egypt, and England, and passed the later years of his life in Rome; everywhere giving lectures on grammar, theology, and astronomy. He left treatises on astrology and some poems; but his most important works are his Commentaries on the Old Testament.

Aber is a Celtic word which enters into the composition of several names of places, chiefly in Wales and Scotland. It indicates the mouth or embouchure of a stream, either into the sea, or into another river—as Aberbrothock, at the mouth of the Brothock, in Pembrokeshire; Abergavenny, at the junction of the Usk and Gwenny, in Wales.

Aberavon, a municipal borough and seaport in Glamorgan, on the Avon, near its mouth in Swansea Bay, 32 miles W. of Cardiff, with great copper, iron, steel, and tinplate works. It has a good harbour and docks, and was till 1918 one of the Swansea parliamentary boroughs. Pop. 15,000.

Abercarn, in Monmouthshire, 10 miles NW. of Newport, is in a great coal and iron mining district, with tinplate and other iron manufactures; pop. 20,000.

Abercorn, a Linlithgowshire hamlet, near the Firth of Forth, and $3\frac{1}{4}$ miles W. of South Queensferry. Here stood the monastery of Aebbercurnig, or Eoricorn, which, founded about 675, was from 681 to 685 the seat of a bishopric, the earliest in Scotland. For the ducal title of Abercorn, see HAMILTON.

Abercrombie, JOHN (1780–1844), Scottish physician, was born at Aberdeen, a parish minister's son. He studied and practised medicine in Edinburgh; and after the death (in 1821) of the celebrated Dr Gregory, was recognised as the first consulting physician in Scotland. He wrote on the pathology of the brain and on diseases of the stomach. But he is best known by his *Intellectual Powers* (1830) and *Moral Feelings* (1833).

Abercrombie, LASCELLES, born 9th January 1881, was educated at Malvern and Manchester University, became lecturer in poetry in Liverpool University in 1919, professor of English at Leeds in 1922. Besides studies of Thomas Hardy, the epic, *Theory of Art* (1922), *The Theory of Poetry* (1924), and *The Idea of Great Poetry* (1925), he published *Interludes and Poems* (1908), *Mary and the Bramble* (1910), *Deborah* (blank-verse drama, 1913), and *Short Plays* (1922), which quickly established his name as a poet with metaphysical leanings.

Abercromby, SIR RALPH, was born at Menstrie, Clackmannanshire, 7th October 1734. Destined for the Scottish bar, he was educated at Rugby, and then from 1752 to 1755 studied law at Edinburgh and Leipzig. But having in 1756 obtained a cornetcy in the 3d Dragoon Guards, he two years later saw some active service in the Seven Years' War. From 1774 to 1780 he represented Clackmannanshire in parliament; and in 1780 raised a regiment in Ireland, the 103d, or King's Irish. In 1793 he accompanied the Duke of York to Holland. His conduct throughout that unfortunate campaign, especially during the disastrous retreat in the winter of 1794–5, won him the love and admiration of the whole army. On his return to England, he was made a Knight of the Bath, and was appointed to the chief command of the West Indies Expedition, which he conducted with distinguished success. In 1797 he was sent to command the forces in Ireland; but his enlightened and manly remonstrances against the policy of government towards that country occasioned his removal to a similar command in Scotland. In 1799 he was second in command to the Duke of York in the other unhappy expedition to Holland. On his return, he received the command of the expedition to the Mediterranean. The fleet anchored in Aboukir Bay on 2d March 1801; and before mid-day of the 8th, the British troops were in possession of the sand-hills which command the shore, having landed in the face of a storm of shot. On the morning of the 21st, Menou, the French commander, attempted to surprise the British camp. He found them ready, under arms. In the glorious action that ensued, Abercromby was struck by a musket-ball in the thigh; but not till the battle was won did he show any sign of pain. The ball could not be extracted; mortification ensued; and on the 28th he died on board the flag-ship. He was buried at Malta, and a monument was erected to him in St Paul's. The peerage conferred on his widow was afterwards enjoyed by his eldest son, with the title of Baron Abercromby.—His third son, **JAMES** (1776–1858), entered parliament in 1807, held the office of Speaker (1835–39), and was then created Baron Dunfermline. He was author of a Memoir of the last eight years of his father's life (1861).

Aberdare, a town of Glamorganshire, part of Merthyr-Tydvil parliamentary borough, exports coal; pop. 55,000

Aberdare, HENRY AUSTIN BRUCE, LORD (1815–95), born at Duffryn, Glamorganshire, was Home Secretary (1868) and President of the Council (1873–74), with a peerage (1873). After him as President of the Royal Geographical Society the Aberdare Range in Africa was named.

Aberdeen, the chief city and seaport in the north of Scotland, is 98 miles NNE. of Edinburgh as the crow flies, and 528 NNW. of London. (The distances by rail are rather longer.) The burgh, which lies at the mouth of the Dee—the Don being 2 miles north of it—was founded somewhere about the 7th or 8th century. It was raided by Eystein, king of Norway, about 1150, and from that period it emerges into definite recorded history. It has been a royal burgh, with the right of foreign trade, since the time of David I. (1033–1153). The patron saint was St Nicholas (Santa Claus), to whom the mother-church of the city was dedicated, and it still bears his name. The figure of the patron saint was on the burgh seal, or coat of arms, up to 1430. Old Aberdeen (the name is a misnomer) is within the same parliamentary and municipal boundary. It had no history till Bishop Elphinstone had the precincts of the cathedral and the newly established King's College erected into a burgh of barony, with the bishop as baron, in 1498. Aberdeen is notable for its historical associations, for its educational record, its commercial enterprise, and its aspect as a city. The castle of Aberdeen, that stood on what is known still as the Castlehill, and was held by an English garrison for Edward I., was stormed by the forces of Robert the Bruce in 1308, and was then demolished. The hexagonal arcaded Market Cross (successor of an earlier one) was erected in 1686, on the model of the Market Cross of Edinburgh—the removal of which Sir Walter Scott so lamented in *Marmion*. It is now the finest historical market cross in Scotland, distinguished in particular by its general design, its central sculptured shaft and unicorn, and the medallion portraits of Stuart sovereigns that ornament the frieze. The cathedral, dedicated to St Machar, is the only granite cathedral in the British Isles. The Bridge of Balgownie, near the cathedral, a fine Gothic structure from the 13th century, is the oldest historical bridge of Scotland still in use; and the Bridge of Dee, built by Bishop Gavin Dunbar, 1520–27, is unique among the bridges of Britain for its (28) inscriptions and coats of arms. Education has been a leading interest of the city for centuries. In 1494 Bishop Elphinstone founded King's College and University, and in 1593 Marischal College and University was founded by the Earl Marischal. In 1860 these colleges were formed into one university, now fully equipped for arts, medicine, science, and divinity. Latterly great extensions have taken place in buildings and in provision for higher legal, technical, and commercial education. The city has over thirty splendid primary and secondary schools, all fully and keenly in use. The trade of Aberdeen has been of consequence since the 13th century. As the wardrobe accounts of Edward I. show, part of the provisions of the English armies that invaded Scotland consisted of dried fish from Aberdeen. The trade of the city now—both rail and sea-borne—is remarkably varied. Next to Grimsby it is the largest fish-supply centre in the British Isles. Its granite-trade has been remarkable since the later years of the 18th century, and its other industries include comb-making, paper-making, shipbuilding, cattle-breeding, grain-milling; linen, cotton, woollen, wincey, tweed, hosiery, and worsted glove manufactures; soap and candle-making, chemical-works, provision-curing, printing and book-binding, coach and motor-car building, engineering of all kinds, timber-working, &c. The main streets of the city are well laid out, and have a singular air of spaciousness that gives distinction to the appearance of the city. Since about 1820 the light-gray granite of the district, finely dressed, has been used in the buildings of Aberdeen, which, from this cause, has become known as the 'Granite City.' The city has six public parks, besides the

links; and the amenities of the city include statues in the main thoroughfares of the Duke of Gordon, first colonel of the Gordon Highlanders, of which Aberdeen is the depot (a granite statue by Thomas Campbell); General Gordon (bronze), by J. Stuart Burnett, A.R.S.A.; Queen Victoria (bronze), by C. B. Birch, A.R.A.; Edward VII. (granite), by Alfred Drury, R.A.; and a colossal bronze statue of Wallace, by W. Grant Stevenson, R.S.A. Five golf-courses are in use at Aberdeen, including the municipal course on the links, where golf has been played since before 1625. Literature and the fine arts have flourished in the city, more or less, since the days of Archdeacon Barbour, the father of Scottish poetry and history. The roll of distinctive names includes Boece, the historian; Arthur Johnston, Latin scholar and poet; George Jamesone, the first British portrait-painter of eminence; Andrew Robertson, miniaturist; James Beattie, of the 'Minstrel'; the Gregorys; W. Dyce, R.A.; J. Phillip, R.A.; Sir George Reid, P.R.S.A.; James Gibbs, architect; Sir James McQuig, founder of the modern British Army Medical Service; James Skene of Rubislaw, friend of Sir Walter Scott; his son, W. F. Skene, historiographer royal; John Hill Burton, historian; George Macdonald, novelist; Walter C. Smith, poet-preacher. The population of Aberdeen was nearly stationary up till A.D. 1700, when it was only about 6000. In 1800 it had increased to about 25,000, and at the census of 1921 it was 138,963. The town council consists of thirty-four members, including the Lord Provost and six bailies. Formerly, as in other Scots burghs, the chief magistrate was known as 'Alderman,' but in 1501, following the lead of Edinburgh, Aberdeen discontinued the English title, and has used 'Provost' and 'Lord Provost' ever since. The parliamentary burgh is divided into the north and south divisions, each represented by one member.

Works on Aberdeen: *Annals*, W. Kennedy (1818); *Book of Bon Accord*, Joseph Robertson (1839); *Aberdeen: Traditions and History*, W. Robbie (1893); *Historical Aberdeen*, G. M. Fraser (1905); *Old Aberdeen*, Ella Hill Burton Rodger (1902); *Aberdeen University* (various works), P. J. Anderson; *History of the University*, J. M. Bulloch (1895); *Universities of Aberdeen*, R. S. Rait (1895).

Aberdeenshire, the fifth in size and the most easterly of the Scottish counties, has a maximum length of 102 and breadth of 50 miles, with 65 miles of sea-coast and an area of 1970 square miles. It has a south-west and north-east direction. Of the whole area almost exactly 50 per cent is under cultivation. The county is almost purely agricultural, with sheep and cattle breeding, and as a cattle-breeding and cattle-feeding area it is unsurpassed in Scotland. The chief crops are oats, barley, and turnips; and the soil—clay near the coast, loam towards the middle, and gravelly, sandy, and peaty elsewhere—is cultivated to its utmost capacity. Inland the county is hilly, and in the upland south-western region it becomes mountainous, the lofty Grampian range forming part of its boundary. The scenery in those parts is desolate and grand. Remains of early culture are abundant in the county in the form of stone circles, hill forts, earth-houses, prehistoric cairns and grave-mounds, and sculptured stones; and the number of feudal castles is quite remarkable. No fewer than eighty-one such exist in the county, in ruins or still occupied, dating from the 14th century onward. Balmoral Castle is the chief seat, but dates only from 1853-56, whereas Drum Castle, near Aberdeen, has been occupied continuously by the Irvine family since the property was granted to them by Bruce. The Romans crossed the county at Culter, about 7 miles west of Aberdeen, where a turf camp exists, connecting on the one

hand with Raedykes Camp, Stonehaven, and on the other with Glenmailen Camp, Ythan Wells, both of which have been excavated, and found to be of typical Roman construction. The chief towns of Aberdeenshire are Aberdeen, Peterhead, Fraserburgh, Huntly, Inverurie, Kintore, Turriff, Ellon, Oldmeldrum, Ballater, and Braemar. The rainfall is moderate, and the mean temperature, while slightly under the average for Scotland in summer, is slightly above the average in winter. Education is on a high level, and industry, thrift, and intelligence are markedly characteristic of the people.

See *The Making of Aberdeenshire*, by W. Alexander (1888); *Aberdeenshire*, by A. Mackie (1911); *History*, by W. Watt (1900). The population is 300,980.

Aberdeen, GEORGE HAMILTON GORDON, EARL OF, was born at Edinburgh, 28th January 1784. He was educated at Harrow and at St John's College, Cambridge, where he took his M.A. in 1804. On succeeding to the earldom in 1801, he had made a tour through Greece; hence Byron's line: 'The travelledthane, Athenian Aberdeen.' In 1806 he was elected one of the Scottish representative peers, and entered the House of Lords as a Tory. In 1813 he was appointed ambassador to Austria, and conducted the negotiations which led to the alliance of that power with Britain. At this time he formed a close friendship with Prince Metternich which decidedly influenced his policy. On the conclusion of the war, he was raised to the British peerage as Viscount Gordon. In 1828 he took office in the Wellington ministry. The general principle which guided his policy as Foreign Secretary was that of non-interference in the internal affairs of foreign states, which, joined to his sympathy with such statesmen as Metternich, exposed him—not always justly—to the suspicion of hostility to the cause of popular liberty. His gradual abandonment of high Tory principles was evinced by his support of the repeal of the Test and Corporation Acts, and of the Catholic Emancipation Act. For eleven years after the fall of the Wellington ministry he remained out of office, with the exception of his brief administration of the Colonial Office in the Tory government of 1834-35. In 1841 he again became Foreign Secretary, his chief services as such being the conclusion of the Chinese war, the Ashburton Treaty, and the Oregon Treaty. With Guizot he acted in cordial alliance. His act (1843) for removing doubts regarding the admission of ministers to benefices in Scotland could not heal the Disruption, and was virtually repealed by the Act for the Abolition of Patronage, 1874. Like Peel, he was honestly converted to free-trade principles, and with Peel he resigned in 1846, immediately after the repeal of the Corn Laws. In 1852, on the resignation of Lord Derby, Aberdeen became head of a popular coalition ministry, which lost credit owing to mismanagement in the Crimean War (q.v.). The government was defeated by Mr Roebuck (q.v.), and in February 1855 Aberdeen resigned. He died in London, 13th December 1860. See *Lives* by his son (1893), Lady F. Balfour (1922).—His grandson GEORGE (1841-70), 'the Sailor Earl,' drowned at sea, was succeeded by his brother JOHN (b. 1847), seventh earl and first marquess (1915), Lord-lieutenant of Ireland (1886 and 1905-15), and in 1893-98 Governor general of Canada.

Aberdevine. See SISKIN.

Abergavenny (the Roman *Gobannium*), a market-town of Monmouthshire, at the influx of the Gavenny to the Usk, 13 miles W. of Monmouth. It has remains of an old castle and of a priory. There are collieries and ironworks in the neighbourhood. Pop. 9000.

Abernethy, a small police-burgh of Perthshire, near the Earn's influx to the Tay, 8½ miles SE. of

Perth. The ancient capital of the Picts, and from 865 till 908 the seat of the sole Scottish bishopric, it retains one of the three Round Towers (q.v.) in Scotland, 73 feet high Pop. 600.

Abernethy, JOHN, an eminent English surgeon, was born in London, 3d April 1764. His grandfather, the Rev. John Abernethy (1680-1740), an Irish Presbyterian clergyman, acquired distinction by his controversial writings. Abernethy was educated at Wolverhampton grammar-school, and in 1779 was apprenticed to the assistant-surgeon at St Bartholomew's Hospital. In 1787 he was himself elected assistant-surgeon to St Bartholomew's, and soon after began to lecture on anatomy and surgery. At first, he manifested extraordinary diffidence, but his power soon developed itself; and his lectures at last attracted crowds. His clear, simple, positive style, illustrated by an inexhaustible fund of apt anecdotes, made him the most popular medical teacher of his day. In 1813 he was appointed surgeon to Christ's Hospital, in 1814 Professor of Anatomy and Surgery to the College of Surgeons, and in 1815 full surgeon to St Bartholomew's, a post which he resigned in 1829. His practice increased with his celebrity, which the eccentricity and rudeness of his manners contributed to heighten. He died at Enfield, 28th April 1831. Of his Works (4 vols. 1830) the most original and important is his *Observations on the Constitutional Origin and Treatment of Local Diseases* (1809), in which a simple principle, till then little attended to, was made the foundation of much important and ingenious observation. See his *Life* by George Macilwain (3d. ed. 2 vols. 1857).

Aberration of Light is an apparent alteration in the place of a star, arising from the motion of the earth in its orbit, combined with the progressive passage of light. When rain is falling perpendicularly, a drop entering at the top of an upright tube at rest, will go through; but if the tube be carried forward horizontally, a drop entering the top will strike against the side before it goes far: to make the drop go through the tube in motion, we must incline the top of it forward in the direction of the motion. The amount of this inclination will be the greater, the more rapid the motion of the tube is compared with that of the falling drops. If

in the time that a drop takes to fall through the height, AB, of the parallelogram in the annexed cut, the inclined tube, BC, is moved horizontally over a space equal to its breadth AC, a drop entering the top of the tube will descend without touching the sides. For in half the time, the tube will be in the position B'C', and the drop in the position d; and so for any other portion of the time. This exactly illustrates the astronomical phenomenon in question. The tube is a telescope directed to receive the light of a star; this tube, and the person looking through it, are moving along with the earth in its orbit, and the light may be conceived as particles coming from the star like drops of rain, moving much faster no doubt, still requiring time. That a particle or ray of light from the star may pass through the tube, it must be directed, not straight to the star, but at a slight angle in the direction of the earth's motion. Thus the place where we see the star is not its true place. As the earth's motion, however, is slow compared with the velocity of light, the angle of inclination is small—never exceeding about 20". The result is, that, if we conceive the true place of

a star as a fixed point, the apparent place of the star describes about this true place, in the course of a year, an ellipse whose greater axis is about 41". In the case of stars near the pole of the ecliptic, this ellipse approaches to a circle, while for stars in the plane of the ecliptic, it contracts to a line about 41" long. The aberration of light was discovered by the English astronomer Bradley in 1727, while seeking to determine the parallax of certain fixed stars—For spherical and chromatic aberration, see LENSES.

Aberystwyth, a seaport and municipal borough of Cardiganshire, on the Ystwyth, at its mouth in Cardigan Bay, 244 miles NW. of London by rail. It is the seat of the University College of Wales (1872; partly burnt 1885, and rebuilt 1887), with a principal and staff of over twenty professors or lecturers, and of the National Library of Wales (1911). There are remains of a castle (1109). Its fine situation and climate combine with its marine terrace and promenade pier to make Aberystwyth a favourite bathing-place. Till 1885 it was one of the Cardigan parliamentary boroughs. Pop. 13,000.

Abeysance, an English law term importing that a hereditament, dignity, or office is not vested in any one, but is suspended, until the true owner appears, or the right thereto is determined. Titles of honour are said to be in abeyance when there is for a time no person entitled to them. Thus where a peer holds the peerage to him and the heirs of his body, and dies, leaving only daughters, the peerage is in abeyance. So, when a parson dies, the life-interest, or freehold, of the benefice is in abeyance until his successor is appointed. The abstract right of property in the benefice is in perpetual abeyance, because no existing parson is ever entitled to more than the life interest.

The property in a vessel captured at sea, until condemned as a prize, may be in abeyance. The remainder or reversion in fee, where there is a tenant of the freehold, may for a time be said to be in abeyance when without any particular owner. The right of a citizen to vote may be held in abeyance, when he is not allowed to exercise that right.

Abgar is the name or title of twenty-eight princes of Edessa (q.v.) in Mesopotamia. The most notable of these princes is the fourteenth of the name, a contemporary of Jesus, and was said to have written a letter to Jesus, and to have received an answer from him. These letters, translated into Greek from the Syriac by Eusebius of Caesarea, were denounced as spurious by Pope Gelasius in 494, and soon lost all credit. The letter from Abgar contains a request that Jesus should visit him, and heal him of a certain disease. In the reply, Jesus is represented as promising to send a disciple to heal him after his ascension. For other fables in this connection, see Lipsius, *Die Edessanische Abgarsage* (1880).

Abhorers, the name of the court party in the reign of Charles II. (afterwards *Tories*) who *abhorred* the views of the *addressers*, or opponents of the royal prerogative.

Abi'athar, a Hebrew high-priest in the time of David. For his share in Adonijah's rebellion, he was deprived of the priestly office, and banished by Solomon from Jerusalem.

Abich, WILHELM HERMANN, geologist and traveller, was born at Berlin, December 11, 1806. He studied at Berlin, became professor at Dorpat in 1842, Fellow of the St Petersburg Academy in 1853, and after 1877 lived at Vienna. He explored the Caucasus region, the Armenian highlands, and Northern Persia, and his published works are invaluable geological and meteorological memoirs on these countries. He died 2d July 1886.

Abies. See FIR.

Abigail, wife of Nabal, a wealthy chief at Carmel, who refused common hospitality to David when an outlaw from the court of Saul. David was on his way to punish Nabal for his churlishness, when Abigail hastened to meet him with a present, and so charmed him that, on the death of her husband soon after, he at once took her to wife (see 1 Sam. xxv.).—The name *Abigail* has passed into a general name for a waiting-maid or lady's-maid, from the title of 'handmaid' applied to herself by Abigail in her address to David.

Abimelech, (1) a Philistine king at Gerar, who took to his harem Sarah, whom Abraham had, for safety's sake, represented as his sister instead of his wife, but restored her in consequence of a divine command given him in a dream. See the story in Gen. xx.—(2) A son of the Hebrew judge Gideon by a Shechemite mother, who made himself king of Shechem, first murdering all his seventy brethren except the youngest, Jotham. After a reign of three years, he was wounded to death by a stone thrown by a woman while he was besieging the tower of Thebez, held by his insurgent subjects (Judges ix.).

Abingdon, a municipal borough of Berkshire, situated at the junction of the Ock and the Thames, 6 miles S. of Oxford, and 60 WNW. of London. 'Abbandun' (Abba's hill) was an important place in the 8th century, and its Benedictine abbey, rebuilt in 955, was very rich. It has two old churches, a school founded in 1563, and a clothing manufactory. Till 1885 Abingdon returned a member to parliament. Pop. 7000. See a history by Townsend (1910), and that of the abbey by Stenton (1913).

Abingdon, a town of Virginia, with two ladies' colleges and cigar and wagon factories; pop. 2500.

Abinger, BARON. See SCARLETT.

Abington, a manufacturing town of Massachusetts, 20 miles SE. of Boston; pop. 6000.

Abington, FRANCES (1737–1815), a daughter of a common soldier called Barton, from being a flower-girl about the London theatres, passed to the stage in 1755. She married Abington, her music-teacher, but soon separated from him; played under Garrick at Drury Lane and at Covent Garden; was the original Lady Teazle; and at her retirement in 1799 was the first comic actress on the stage.

Ab'logenesis, a term applied by Huxley in 1870 to Spontaneous Generation (q.v.).

Abipones, a powerful and war-like tribe of South American Indians in the Gran Chaco (q.v.), now extinct, who were very formidable enemies to the Spaniards.

Abjuration. See ALLEGIANCE.

Abkhasia, or ABASIA, a district of Georgia, between the Caucasus and the Black Sea, with Mingrelia to the SE. It is mountainous, with deep, well-watered, and fertile valleys. The population, some 30,000 in all, is partly Mingrelian, partly Abkhasian (see CAUCASUS), many of the Abkhasians having migrated to Turkish territory before and after 1878. Russia took possession of Abkhasia in 1824, but subdued the people only in 1864.

Ablaut is the variation of the vowel of a root, depending apparently upon the position of the accent in the parent Indo-Germanic language. It appears especially in the various tenses of the verb in English, German, and Greek. Thus in *drive*, *drove*, *driven*, the original vowels were *ei*, *oi*, *i*, as in Greek *leipō*, *lelōpa*, *elipon*. The German name for this gradation has now been generally adopted. Compare UMLAUT.

Ablution, a ceremonial washing of the whole body, or some part of it (commonly the hands),

for the purpose, not of material cleansing, but of special consecration before prayer or other religious observance, or for purification from ritual uncleanness or tabu. The custom is widespread. Various liquids have been used, as the blood of a pig for the purification of a homicide among ancient Greeks and modern Nicobar Islanders. In the Taurobolium of the Attis cult the worshipper stood under a grating and was drenched with the blood of a bull sacrificed above. Nor is the notion of the washing away of sins by blood unknown to Christians, though no such rite be actually practised among them. Water, however, is the usual medium. Among primitive peoples in all parts of the world uncleanness is incurred by the shedding of blood (whether the act be held a crime, an ordinary necessity, or an honourable exploit), by any association with death or birth, by the performance of sexual functions, by contact with that which is unclean, and by other acts and accidents. The unclean person is subject to tabu, and danger to himself and those whom he may infect—danger from the ghost of the slain, for example—can only be averted by purifying rites into which seclusion, hair-cutting, fire, sacrifice, fasting, and the like may enter, as well as bathing.

The laws prescribing the washing of the whole body in such emergencies among the Jews are to be found scattered through the books of Leviticus and Numbers. Washing of hands is practised today by the Jews before every meal at which bread is eaten, before prayer, after unclean bodily functions, and after contact with an unclean object. A dry clean substance (as a cloth) may be used when water is unobtainable.

The Mohammedans perform ablutions before their prescribed prayers (five times a day), before touching the Koran, and after ritual defilement. See also BAPTISM, CHURCHING OF WOMEN, HOLY WATER, LUSTRUM, TABOO.

Abner, a famous Hebrew captain, cousin of King Saul. He fought bravely in the long struggle with the Philistines, and after Saul's defeat and death at Mount Gilboa saved the crown for his son, Ishbosheth. At last, resenting a charge made against him by his master, he went over to David; but he was soon after murdered by Joab.

Åbo (Finnish *Turku*), the second town of Finland, on the Aurajoki, near the Gulf of Bothnia, 170 miles WNW. of Helsingfors by rail. It has a winter harbour, and is one of Finland's chief commercial and industrial towns. Founded in the 11th century, capital of Finland till 1819, Åbo is still the seat of the archbishop and an appeal court. Its university was transferred to Helsingfors after the great fire of 1827. A new Swedish university was founded in 1918; a Finnish in 1922. There is a 12th-century castle. A peace between Sweden and Russia was signed here in 1743. Pop. 60,000, over a fifth Swedish.

Abolitionists, a party in the United States who sought the immediate and total abolition of slavery, politically important from about the close of the 18th century. Abolitionist views had long been held by many, especially by members of the Society of Friends; but the term was not commonly used until an aggressive party spread from New England throughout the north and west. After about thirty years of agitation, the abolitionists got some of their doctrines adopted by the republican party. Their ends were gained when, under Lincoln's administration, slavery was abolished, 1863–65. See GARRISON, SLAVERY.

Abomey. See DAHOMEY.

Abor Hills, a district on the borders of Assam and Tibet, inhabited by a wild people of Mongolian type, the Abors.

Aboriginés (Lat.), properly the earliest inhabitants of a country. The corresponding term used by the Greeks was *Autochthónes*. The Roman and Greek historians, however, apply the name Aboriginés to a special people, who, according to tradition, had their original seats in the mountains about Reate; but, being driven out by the Sabines, descended into Latium, and in conjunction with a tribe of Pelasgi, subdued or expelled thence the Siculi, and occupied the country. The Aboriginés then disappear as a distinct people, they and their allies the Pelasgi having taken the name of Latini. The non-Pelasgic element of the Roman population is supposed to represent these Aboriginés, who would thus belong to the Oscans or Ausonians. The name is applied generally to the original or native inhabitants of a country as opposed to an intrusive conquering race, or to colonists and their descendants.—An Aboriginés Protection Society was founded in 1838, to take all possible means for protecting the natives of various countries from murder and ill-usage generally at the hands of colonists and other white men.

Abortion is the term used in Medicine to denote the expulsion of the product of conception (the impregnated ovum) from the womb before the sixth month of pregnancy. If the expulsion takes place after that date, and before the proper time, it is termed a *premature labour*. *Miscarriage* is a popular term covering both. The frequency of abortion as compared with normal pregnancy is very differently estimated by different writers; but the best evidence leads us to the belief that abortion is of far more common occurrence than is generally supposed, and that it takes place on an average in one out of every six or seven cases of pregnancy. The following are amongst the *causes predisposing* to this accident: (1) a diseased condition of either parent, and especially a syphilitic taint; (2) most fevers, and many other acute diseases occurring during pregnancy; (3) any condition interfering with the health of the mother—e.g. the constant breathing of impure air, insufficient nourishment, hard work, &c.; (4) disorders and displacements of the womb, &c. Amongst the *direct causes* of abortion may be placed blows on the abdomen, falls, any violent muscular efforts, too long a walk or ride on horseback (indeed, women with a tendency to abort should avoid violent exercise during pregnancy), a severe mental shock, &c. Moreover, the death of the fœtus from any cause is sure to occasion abortion.

Symptoms.—Abortion is sometimes preceded by feverishness, shiverings, a feeling of weight in the abdomen, or other discomfort. But the first certain indication of threatened abortion is usually hemorrhage, followed, if not arrested, by pain, which after the second month more or less resembles the pain attending normal labour.

In the *treatment* of abortion, prophylactics (or the guarding against causes likely to lead to it) hold the first place. Women liable to this affection should, on the slightest threatening, assume as much as possible the horizontal position, avoiding all bodily exertion or mental excitement. They should use non-stimulating foods and drinks, and keep the bowels open by gentle aperients—such as fruit and castor-oil—and carefully avoid aloes and other medicines irritating the lower bowel. Moreover, a separate bedroom must be insisted on by the physician. We shall only enter into the curative treatment so far as to state that if it is deemed necessary to check hemorrhage before professional aid can be called in, cloths soaked in cold water may be applied locally (care being taken to change them before they grow warm), and iced water, together with a small dose of laudanum (10 drops), may be

given internally. Further proceedings must be left to the medical attendant. At least as much attention must be paid to rest subsequently as after a normal labour; for abortion, if not very carefully attended to, is one of the most frequent causes of uterine disease.

There are occasional cases (as where the outlet of the pelvis is very contracted) in which it is necessary to induce abortion by professional means, but it would be out of place to enter into this subject in these pages. It cannot be too generally known, that all attempts at procuring criminal abortion, either by the administration of powerful drugs, or the application of instruments, are accompanied with extreme danger to the pregnant woman.

CRIMINAL ABORTION.—Neither in the law of England nor of Scotland is it murder to kill a child in the mother's womb (although it would be murder of the mother, if she died in consequence of the treatment). Such a crime is called criminal abortion, and in England is defined by statute as the unlawfully administering to a woman any poison or noxious drug, or using any surgical instrument or other means, with the intent of procuring miscarriage, whether the woman be pregnant or not. A pregnant woman may commit this crime on herself. In Scotland procuring abortion is a crime at common law, and in both countries it is punished by penal servitude or imprisonment, according to circumstances. Moreover, any one who supplies or procures a drug or instrument, knowing that it is intended to be unlawfully used to bring about the miscarriage of a woman, is punishable. There is a regular trade in abortion, mechanical violence being most often employed to produce the effect. The drugs used are divided into the class of emmenagogues and that of ecbolics, ergot of rye being the most popular. There are many predisposing causes to abortion, both in the mother and in the fœtus, which must be allowed for.

In the United States abortion is a crime at common law, and severely punished by fine and imprisonment. The common law has been strengthened by various statutes directed against attempts to procure miscarriage. Consent of the woman is no defence. It is a misdemeanour for any person knowingly to deposit for mailing or delivery any article or thing designed or intended to procure abortion.

In biology the term abortion is used for the arrested development of an organ, which is reduced to a vestige or rudiment.

Aboukir is a small village on the coast of Egypt, 13 miles N.E. of Alexandria. Near it is the ancient Canopus (q.v.). Aboukir stands at the west end of the Bay of Aboukir, which stretches eastwards to the Rosetta mouth of the Nile. This bay is celebrated on account of Nelson's great victory over the French fleet, August 1, 1798, the famous 'Battle of the Nile.' The French fleet was not merely defeated, but almost annihilated; the flagship of the admiral De Brueys blew up, and only two ships escaped. Here Napoleon in 1799 defeated a Turkish army; and here Sir Ralph Abercromby's expedition landed in 1801 in the face of the enemy.

Abousambul. See ABUSIMBEL.

About, EDMOND FRANÇOIS VALENTIN, an eminent French author, was born at Dieuze, in Lorraine, February 14, 1828. After a brilliant course at the Lycée Charlemagne and Ecole Normale in Paris, he went for two years to study archæology at Athens, and on his return about the end of 1853, he published *La Grèce contemporaine*, a clever popular satire on modern Greek society. Its success opened to the young author the columns of the Paris journals, and in the *Revue des Deux Mondes* ere long appeared his first novel, *Tolla Feraldi*, republished

in 1855. About was accused of having taken many of the incidents of this story from a little-known Italian book, *Vittoria Savorelli*, and his reputation hardly recovered this charge until the appearance in the *Monteur* of his series of stories, *Les Mariages de Paris*. From that time his literary career was a series of successes. His next novels were *Le Roi des Montagnes* (1856), a story full of humorous incident, which pleased everybody except the Greeks; and *Germaine* (1857), a clever story of contemporary Parisian life. Four other novels of note must be named: *Les Échasses de Maître Pierre* (1858), *Madelon* (1863), *La Vieille Roche* (1865), and *Le Roman d'un Brave Homme* (1880), the last an attempt, that had less success than it deserved, to show the French public that a novel may be interesting and yet fitted for general reading. None of About's works deserved their popularity more than his three short fantastic tales, *L'Homme à l'Oreille Cassée*, *Le Nez d'un Notaire*, and *Le Cas de M. Guérin*, all published in 1862; while his *Trente et Quarante* (1865), *L'Infâme* (1867), and *Les Mariages de Province* (1868), would of themselves have made a reputation. About contributed constantly to the journals of the day, and wrote many plays, few of which, however, were successful on the stage. As a publicist, he enjoyed a wide though mainly factitious reputation, several of his pamphlets being understood throughout Europe to be written with the approval of the Emperor of the French. As a newspaper correspondent he was present at the opening of the Suez Canal, and accompanied MacMahon in the Franco-German war. His *Alsace* (1872) and some newspaper articles cost him a week's imprisonment at the hands of the German authorities, who chose to treat him as a German subject, because he had been born in Lorraine. About had been decorated with the Cross of the Legion of Honour in 1868, and in 1884 received the coveted distinction of election to the Academy, but died just before he was formally received, January 17, 1885.

Abacadabra, a magical word or formula constructed out of the letters of the alphabet, and supposed to be highly efficacious for the cure of agues and fevers. The letters were written so as to form a triangle, capable of being read many ways on a square piece of paper, which was folded or stitched into the form of a cross; worn as an amulet in the bosom for nine days; and ultimately thrown backward before sunrise into a stream running eastward. The adjoining is one way of arranging this mystic word.

Abraham. Our knowledge of Abraham is obtained from the account of his life in Gen. xi.-xxv., and this was derived by the author of Genesis from the three sources of the Pentateuch (q.v.) known as P., J., and E. Putting the facts together, the following is a brief summary of his career. Abraham, originally known as *Abram*, was the son of Terah, a descendant of Shem, and was born in Ur of the Chaldees. This site, long supposed to be at Edessa or elsewhere in the north of Mesopotamia, is by Schrader and most recent scholars (Tiele dissenting) identified with the ruin-mounds of El Mugheir, low down on the western side of the Euphrates. In Ur, Abraham married his half-sister Sarai (afterwards Sarah). From Ur, Terah with his family migrated up the valley of the Euphrates to Haran, in the north-west of Mesopotamia;

and there Terah died. Abraham, accompanied by his nephew Lot, and apparently at the head of a numerous following, received a call from Jehovah, in obedience to which he passed west and south into Canaan, and established himself for a time at Sichem. Thence as a nomadic chief or sheikh he wandered towards the South, and was driven by famine into Egypt, where Sarah was taken by Pharaoh into his harem. A similar outrage is represented as having befallen her at the hands of Abimelech, the Philistine king of Gerar, when well advanced in years. (See Gen. xx., and compare the story of Abimelech and Rebekah in Gen. xxvi. 9). Returning from Egypt into Southern Palestine, Abraham and Lot parted company; and Abraham pitched his tent at Mamre, near Hebron, which continued the headquarters of his family and tribe until his death. Abraham was wealthy in flocks and herds, and could bring into the field an army of his warlike nomadic tribesmen sufficiently powerful to meet and defeat four kings in battle, so as to rescue his nephew Lot when taken captive. His first-born son, Ishmael, was born to him in his 87th year by Hagar, an Egyptian slave. Jehovah appeared to him more than once; made a covenant with him, granting the land for ever to his descendants; and promised a son by his wife Sarai, whose name was changed to Sarah, as his own was from Abram to Abraham. The rite of circumcision now instituted marked the covenant people from the Canaanites. Sarah's son, Isaac, was born when her husband was 100 years old. Then came the mysterious proving of Abraham by God, when God commanded that Isaac should be offered up as a human sacrifice on a mountain in the land of Moriah, the ram being ultimately substituted for the well-beloved son. Sarah died, and was buried in the cave of Machpelah, near Hebron, in a patch of ground bought by Abraham; and afterwards, apparently when he was upwards of 130 years of age, Abraham married Keturah, and became the father of six sons by her. On his death, at the age of 175, he was buried beside Sarah in the cave.

His life, apart from his special covenant relations, is that of a wealthy and powerful oriental pastoral chief, dignified and generous, true to his word, loyal to his kindred, devoted and faithful to his God. Jews and Christians alike accept him as the type of perfect faith and true religion, 'the friend of God'; 'Ibrahim' is, for all good Moslems, the 'father of the faithful'. Numerous non-scriptural traditions add little of importance to the picture given in Genesis, and completed by allusions in the later Scriptures; though the Mohammedans tell many picturesque tales to illustrate his character; bring Abraham to Mecca to build the Kaaba (q.v.), and believe his remains to have been covered by the famous mosque near Hebron. The later Jews and Mohammedans select Abraham as the incarnation of perfect wisdom, and attribute to him the invention of writing. He was regarded as the ancestor not merely of the Israelites and the Ishmaelite Arabs, but of the other races in Northern Arabia, of Edomites (through Esau), and Midianites.

There has been much discussion among modern scholars as to the historical value of the narrative of Abraham's life. Some regard him as an entirely mythical personage, or as the impersonation of the typical virtues of the religious Israelite. The most common theory regards the story as embodying traditions and recollections of racial movements. Abraham is the leader of a great nomadic movement of the Hebrews who migrated from Babylonia into Palestine. The references to Lot indicate the separation of Moab and Ammon from the original Semitic stock. The introduction of Hagar into the story suggests that the new community inter-

mingled with the primitive inhabitants of Canaan and Egypt. It is unlikely that all the details are to be regarded as literal history. See commentaries by Delitzsch, Dillmann, Skinner, Bennett; Montefiore's *Hibbert Lectures* (1893); also BIBLE.

Abraham, the Plains of, or Heights of, close to the city of Quebec, were the scene of the battle between Montcalm and Wolfe, 13th September 1759. They were so called from A. Martin, a pilot known as 'Maître Abraham.' See WOLFE.

Abraham-a-Santa-Clara, the monastic name of Ulrich Megerle, a very eccentric but popular German preacher, who was born near Moskirch, in Swabia, July 4, 1644, and died in Vienna, December 3, 1709. He was provincial prior of the Augustinians, and court preacher at Vienna. Uncouth puns, sharp and homely satire, and strange freaks of humour, marked his sermons; but under the fantastic shell there was a sound kernel. He was unsparing in his censure of the vices alike of courtiers and the people. His collected works fill 22 vols. (1835-50).

Abraham-men, a class of sturdy beggars who simulated lunacy, and wandered about the country in a disorderly manner; at one time working on the sympathy, and at another on the fears of women, children, and domestics. They were common in Shakespeare's time, and, it would seem, existed even as late as the period of the civil war. The term is a cant one, as old at least as 1561. An 'Abram cove' meant one who personated a 'Tom o' Bedlam.' He 'would disguise himself in grotesque rags, with knotted hair, and with many more disgusting contrivances to excite pity;' but he did not hesitate to live by thieving too, and when detected pilfering, or in any species of depredation, he pleaded 'the immunities of the real Bedlamite, who was formally permitted to roam about the country when discharged from 'Bethlem Hospital.' A verbal relic of this class is still preserved in the slang phrase, 'to sham Abraham.'

Abrantes, a town of Portugal, on the Tagus, 84 miles N.E. of Lisbon; pop. 10,000. Abrantes gave a ducal title to the famous Junot (q.v.).

Abraxas. See GOOSEBERRY CATERPILLAR.

Abraxas Stones are so called from having the word *abraxas* or *abraxax* engraved on them. They are cut in various forms, and bear a variety of cabalistic symbols, mostly composed of a human body, a fowl's head, and serpentine extremities. These gems are common in collections, and are represented as coming from Syria, Egypt, and Spain. The use of the name Abraxas was at first peculiar to the Gnostic sect of the Basilidians; and as the word, by taking the numerical value of its Greek letters, signifies the number 365, the Basilidians used it to indicate the 365 orders of spirits believed by them to emanate from the Supreme God (see BASILIDES). The doctrines and phrases of the sect were carried by the Priscillianists to Spain. But similar symbols were afterwards adopted by all sects given to magic and alchemy; and there is little doubt that the greater part of the abraxas stones were made in the middle ages as talismans.

Abrogation is a term in Law, which means the entire, as distinguished from the partial, annulling of an existing law. The partial annulling of a law is technically derogation. The distinction was recognised in Roman law and adopted by the canon law. The term is used popularly as the equivalent of repeal, whether by statute or contrary usage. The canon law, following Roman law, recognised

the principle of abrogation by non-usage, especially where circumstances changed; thus a canon passed in times of schism might not be enforced when the schism had been suppressed. See DESUETUDE, STATUTES.

Abrus. See PRAYER BEADS.

Abruzzo (or rather the *Abruzzi*), a district of Central Italy, was formerly the north-east corner of the kingdom of Naples, in the wildest and loftiest portion of the Apennines. The jagged mountain-groups reach in the Gran Sasso d'Italia an elevation of 9600 feet. The climate of Abruzzo is raw in the higher regions; snow rests on the hills from October to April, and on some of the peaks all the year round; but the valleys are extremely fertile. Dense forests clothe the sides of the mountains. The Abruzzi used to have three divisions—Abruzzo Ulteriore I. and II., and Abruzzo Citeriore, corresponding to the present provinces, Chieti, Teramo, and Aquila respectively; and forming, with the province of Campobasso, the *compartimento* of 'the Abruzzi and Molise.' The three Abruzzi contain about 4700 sq. m., and 1,100,000 inhabitants.—The DUKE OF THE ABRUZZI, third son of Amedeo, Duke of Aosta (son of Victor Emmanuel of Italy), who was for a time king of Spain, was born at Madrid in 1873. He distinguished himself by climbing Mount St Elias (1896) and Ruwenzori (1906), as well as Mount Kenia; and in 1899-1900 got nearer the North Pole than Nansen. He climbed Mount Godwin-Austen to the height of 24,600 feet in 1909. He commanded the Italian navy (1914-17) in the European war. Books have been published on the Mount St Elias, Ruwenzori, and Karakoram expeditions.

Absalom, the third son of David, king of Israel, remarkable for his beauty, his unnatural rebellion against his father, and his tragic death at the hands of Joab (see 2 Sam. xviii.).

Absalon, Archbishop of Lund. See AXEL.

Abscess (Lat. *abscessus*, a going away), a circumscribed collection of purulent matter formed by disease within some tissue or organ of the body. The process by which an abscess is formed is the following: First, the capillary vessels become overcharged with blood in consequence of inflammation. From the blood thus made stagnant, or flowing very feebly, a much larger amount of fluid than in health, with numerous white blood-corpuscles, exudes through the walls of the capillary vessels, and becomes Pus (q.v.) or matter. This matter, at first contained in the minute interstices of the tissues, gradually breaks them down, and makes for itself a larger cavity; and frequently, by disintegration of the adjacent parts, works its way either to the surface or to some natural cavity of the body. Pus thus makes its appearance often in a different part of the body from where it was formed. The abscess cavity is bounded by an inflamed and swollen layer of tissue; not, however, containing pus. Occasionally, when the purulent matter does not find any outlet either naturally or artificially, it is gradually dried up or absorbed. In the great majority of cases, however, cure only takes place after the pus has been discharged. Abscesses may be *acute*, forming in a few days with much pain; or *chronic* or *cold*, taking weeks or months to form, with little or no pain. In abscesses superficially seated—either in or close under the skin—the early treatment consists chiefly in promoting the formation of pus by the application of moist and warm bandages or poultices. The next step is the removal of the pus. When this is too long delayed, serious disturbance of the organ, and destruction of surrounding structures, may ensue. An abscess

must be regarded not as a distinct, original disease in itself, but as the result of another disease—inflammation; or as an effort of nature for the removal of injurious matters from the system. Abscess is now known in most cases to be caused by the presence of microscopic organisms in the tissues. See GERM THEORY, SUPPURATION

Abscissa, the x -co-ordinate in analytical geometry. See GEOMETRY; also PARABOLA.

Absciss Layer, a layer of cells formed at the base of the stalk in most deciduous leaves. The fall of the leaf is brought about by the splitting of the layer, the portion left on the stem appearing as a leaf-scar, covering the wound with cork. Such leaves are said to be articulate. Others (as those of the oak and beech under certain conditions) are non-articulate.

Absentee, a term applied, by way of reproach, to landlords who derive their rent from one country, and spend it in another. It has been especially used in discussions on the social condition of Ireland. As long as Ireland had its own parliament, a great portion of the large landed proprietors lived chiefly in the country during summer, and passed their winters in Dublin, thus spending much of their incomes among their dependents, or at least among their countrymen. The Union changed the habits of the Irish nobility and gentry, who were attracted to London as the political metropolis, or were induced, by the disturbed condition of Ireland, to choose residences on the Continent. Such Irish landed proprietors were styled 'absentees'; and it was argued that their conduct was the great source of Irish poverty, as it drained the resources of the land, or, in other words, sent money out of Ireland. Another evil result was to place the control of the Irish estates too much in the hands of agents and middlemen. When the landlord does not live among his tenants, there cannot grow up between him and them the sympathy and community of interest required for the general well-being. Absenteeism weakens the sense of responsibility in owners of property, who are too distant to know the real needs and circumstances of the trust committed to them. A great deal of the land of the United States and of Canada and Australia is held by proprietors living in Britain and on the continent of Europe; and so large sums are paid every year to owners who are so remote and know so little of their estates that they cannot possibly fulfil the recognised duties of property. In the Australasian states these objections have taken practical form. The New Zealand graduated land-tax is very much higher for absentees than for resident landowners; the Commonwealth's rate on absentees is also higher.

Absinthe is a spirit flavoured with the pounded leaves and flowering tops of certain species of *Artemisia*, chiefly wormwood (*A. absinthium*), together with angelica-root, sweet-flag root, star-anise, and other aromatics. The aromatics are macerated for about eight days in alcohol, and then distilled, the result being a green-coloured liquor. Adulteration with essential oils of other herbs, or even blue vitriol, is largely practised. The best absinthe used to be made in the canton of Neuchâtel, but the manufacture is now prohibited in Switzerland. When it is to be drunk, the greenish liquor is usually mixed with water; whereupon the precipitation of the contained volatile oil causes the mixture to cloud or whiten. The evil effects of drinking absinthe are very apparent; frequent intoxication, or moderate but steady tipping, utterly deranges the digestive system, weakens the frame, induces horrible dreams and hallucinations, and may end in paralysis or in idiocy. Absinthe came into common use in France through its being

prescribed as a febrifuge to the soldiers during the Algerian war (1832-47); but its sale was forbidden in France in 1915. See WORMWOOD.

Absolute stands opposed to *relative*, and means that the thing is considered in itself, and without reference to other things. In physics, we speak of the *absolute* velocity of a body—i.e. the rate of its motion through space; and of the *relative* velocity of two bodies—i.e. the rate at which they approach or recede from one another, one or both being in motion. In the language of modern metaphysics, the Absolute is the unconditioned, unalterable original—that which is the ultimate cause and ground of the phenomena of the visible world. For the possibility of knowing the absolute, see CONDITION, PHILOSOPHY, RELATIVITY OF KNOWLEDGE, THEISM. In Chemistry, absolute alcohol is pure, unmixed alcohol. See ABSOLUTISM.

Absolution, originally a term of Roman law, signifies acquittal. The word is generally used in an ecclesiastical sense. In the primitive Christian Church, members who had given scandal by gross and open sins were excluded from the Lord's Supper, or from the congregation altogether, and could be readmitted only if they repented and underwent the penance laid upon them by the church. When they had done so, the presbyter, along with the elders, pronounced the absolution in presence of the congregation, and the congregation received the sinner again into their number. After auricular confession became obligatory, absolution was held to convey forgiveness in the sight of God. The formula, *Deus or Christus absoluit te*, which was used till the 12th century, was changed into *Ego absolvo te*. As defined by the Council of Trent, *absolution from sin* is a judicial act by which the priest as judge passes sentence on the penitent, and is a remission of sin made by authority of Christ in the sacrament of penance. It is not a mere declaration that God will pardon those who repent. It has been affirmed by some writers that instead of 'I absolve thee,' a precatory form, such as 'May Christ absolve thee,' uttered by the priest in presence of the person to be absolved, would suffice. But this is disputed. *Absolution from censures*, also granted by the priest with or without the sacrament of penance, is quite different, and merely removes the penalties imposed by the church, and reconciles the offender with the church; whereas absolution from sin gives grace, removes guilt, and reconciles the sinner with God. *Absolution for the dead* is a form said after a funeral mass.

The Protestant churches mostly ascribe to the absolution of the clergy only a declarative, and not an exhibitiv power; on the ground of repentance, it announces and assures forgiveness on the part of God, but does not impart it. From this view must, however, be excepted the Lutheran and Anglican formularies, Luther himself and an entire school of Anglican divines. For the Anglican documents, see the Prayer Book, especially the Exhortation to Holy Communion, and the Office for the Visitation of the Sick. The *catena* of English divines who hold this doctrine is not confined to one school, as it includes Archbishop Usher, and even Baxter. Nor must it be forgotten that the belief in a certain measure of absolving power residing in the whole church was widely spread in the middle ages; and the Sire de Joinville, a layman, tells how he and a brother knight in imminent danger, when no priest was to be had, mutually confessed and absolved each other. Peter Lombard entirely justifies such an act as that of Joinville; Aquinas seems to consider it irregular. In England, Sir John Friend and Sir William Perkins, convicted of having planned the assassination of William III., received at

Tyburn, just before their execution, a solemn and public absolution at the hands of a celebrated non-juring divine, Jeremy Collier. The bishops censured this act on the ground that there was no proof of a previous confession having been made. See **CONFESSION**, **PENANCE**. In Scotch law, the accused in a criminal case is absolved by the forms *absolvitor* or *assoilzie*, on the ground that evidence disproves or does not prove the charge.

Absolutism is a form of government in which the royal power is not limited by any constitutional check. The great era of absolutism in Europe was that which followed on the downfall of the feudal system. The form of monarchy then established was based on the subordination both of the nobles and the church to a strong centralising power, with large revenues and a regular army. The central power was represented by a monarch whose will was supreme. The old feudal nobles were transformed into courtiers. Not only the church, but law, science, and the universities were taken into his service. A professional army took the place of the old feudal militia. For the needs of such a state, a regular revenue, paid in money instead of the feudal payment in kind, was essential. Louis XIV., with his alleged dictum, *L'état, c'est moi* ('I am the state'), may be regarded as the representative absolute monarch. We had a milder form of it in England under the House of Tudor, the so-called personal monarchy. It should be recognised that the absolute centralising monarchy was a necessary stage in the evolution of the modern state. The centralising tendency was necessary for self-defence, and could be effected only by a strong monarch. The ruin of Poland was chiefly due to the fact that it never had a central government vigorous enough to repress the anarchic nobles, and weld the nation into one. The era of absolute monarchs has been virtually closed by the revolutionary movements of 1789 and 1848, the effect of which has been to establish representative institutions in most civilised countries. See **AUTOCRACY**.

Absorption. In Physics, when a quantity of matter or of energy enters into a substance so as to be associated with it in some way (excepting chemical combination in the case of absorption of matter) for a longer or shorter time, it is said to be absorbed by that substance. The nature of absorption differs, of course, with the nature of the thing absorbed and the nature of the absorbing substance. Thus gases are absorbed largely by some solids, the phenomenon being called Occlusion (q.v.) in this case. See also the articles on Solution, Fluorescence, Spectrum (for Absorption-spectrum), and especially that on Radiation. The term absorption is also applied (1) in Animal Physiology to the osmosis of the dissolved matter of the chyle into the vessels of the intestinal villi; (2) in Vegetable Physiology, to the passage of water by endosmosis into the cells of the roots; and also (3) to the initial steps in the process by which the green parts of plants, in sunlight, absorb carbonic acid gas and decompose it. See **PHYSIOLOGY**, **VEGETABLE CHEMISTRY**. For absorption and absolvents in anatomy and medicine, see **DIGESTION** and **LYMPHATICS**.

Abstinence Societies, associations for the promotion specially of abstinence from all kinds of alcoholic liquors. See **TEMPERANCE**.

Abstract, in Law, means a short statement of the contents of a document, such as the *précis* writing in diplomacy, but in England it is used most commonly as the technical name of the summary of the deeds and facts constituting a title to land, which every seller is bound to furnish to the purchaser, unless the contrary has been stipulated. The form of this abstract is in four

columns, each appropriated to a particular class of clauses in the deed, or of facts, such as dates, death, marriage, &c. Like the Scottish progress of titles, the abstract seldom goes back more than twenty years. If there is any defect in the abstract, the purchaser must object within a certain time by making a requisition. In the United States, where conveyancing is less complicated, abstracts are simpler than in England, and are usually prepared at the expense of the buyer.—**ABSTRACT** in Arithmetic is applied to numbers considered in themselves, and without reference to any objects numbered. See also **CONCRETE**.

Abstraction is that intellectual process by which the mind withdraws some of the attributes of objects from the others, and thinks of them to the exclusion of the rest. The abstract is opposed to the concrete. John, William, my brother, form concrete images in my mind, each with a multitude of attributes peculiar to himself. But they have also certain attributes common to them and to all individuals of the race; I can overlook the others, and attend to these, and thus form a notion or conception, which is called a *man*. Man is therefore an abstract notion, the word connoting, as it is called, a certain though not very well-defined number of attributes. With the exception of proper names, all nouns are thus abstract. There are degrees, however, in abstraction. The abstract notion *animal* rises above that of *man*, embracing all men and innumerable organised beings besides. An *organised being*, again, is a still higher stage, and embraces both animals and plants. Being, time, space, are among the highest abstractions. Abstraction is the basis of classification into genera and species (see **GENERALISATION**). The higher abstractions rise, the fewer attributes are implied or connoted in the name. On the other hand, the number of objects to which the name is applicable, increases; and thus reasoning in abstract terms has the advantage of being general, or extensive in its application. But such reasoning is apt to become vague and fallacious, unless constant regard is had to concrete instances.

Absurdum, **REDUCTIO AD**, a method of proving a truth indirectly, by showing that to suppose the proposition untrue would lead to an absurdity, or that the contrary of the proposition is impossible. The method is much used in geometry.

Abt, **FRANZ**, composer of song-music, was born 22d December 1819 at Eilenburg, in Prussian Saxony, and was educated at Leipzig, for a time as a student of theology. From 1841 to 1881 he held musical offices at Bernburg, Zurich, and Brunswick; in the latter year he retired with a pension to Wiesbaden. Of his tuneful settings, more than 200 in number, the best known is 'When the Swallows homeward fly.' He died 31st March 1885.

Abu (Arabic, 'father') is prefixed to many Arabic proper names, as the equivalent syllable *Ab* is prefixed to Hebrew names—*Abu-bekr*, &c. But *Abu*, like *Ab*, often signifies merely 'possessor,' as in *Abulbeda* (possessor of fidelity), 'the Trusty.'

Abu, a mountain of India, in the territory of Shihi, Rajputana, a detached granite mass rising like an island from the plain of Marwar, near the Aravalli ridge, and in its highest point reaching 5650 feet above the sea. It is a celebrated place of pilgrimage, especially for the Jains, who have a magnificent group of five temples at Delwara, about the middle of the mountain, two of which are the most superb of all Jain temples. Both are built of white marble, finely carved, and date from 1031 and 1197 A.D. The mountain contains a beautiful lake (Nakhi Talao) 4000 feet above

the sea; and the region is a hot-weather resort for the government authorities and Europeans.

Abu-bekr ('father of the maiden') was so called as being the father of Ayesha, the wife of Mohammed, was born at Mecca in 573 A.D., and was a man of great influence in the Koreish tribe. He was the Prophet's most trusted follower; and in 632, when Mohammed died, was made the first khalif or successor of the Prophet. Ali, the Prophet's son-in-law, expected the succession, but submitted; the sect of the Shiites (q.v.) to this day protest that Abu-bekr was wrongfully appointed. Abu-bekr had to suppress the relapse of some tribes into heathenism; defeated the false prophet Mosaylima, and after victoriously overrunning Syria and Babylonia in spite of the Byzantine emperor Heraclius, died in 634 A.D., and was buried at Medina, near the grave of Mohammed. See MOHAMMED.

Abu Klea, on the route across country between Korti and Metammeh, both on the great bend of the Nile below Khartum, was the scene of a battle on the 17th January 1885, in which Sir Herbert Stewart defeated the Mahdi's forces.

Abulfaraj (Lat. *Abulfaragius*), called also Barhebræus—as being of Jewish descent—was born in Armenia, 1226, and became distinguished for his knowledge of the Syriac, Arabic, and Greek languages, and of philosophy, theology, and medicine. At the age of twenty, he was made a bishop, and as Bishop of Aleppo rose to the highest dignity among the Jacobite Christians next to Patriarch. Of his numerous writings, the best known is a *Chronicle*, in Syriac, of universal history from Adam down to his own time. Among his theological writings is a commentary on the Syriac version of the Bible.

Abulfeda, ISMAIL-IBN-ALI, a Moslem prince, known as a writer of history, was born in 1273 at Damascus; and during his youth, distinguished himself in several campaigns against the Christian kingdom founded by the Crusaders. He ruled from 1310 over the principality of Hamat in Syria, as an independent ally of the sultan, was a generous patron of literature and science, and died in 1331. He left several important works in Arabic, among which are his *Annals*, one of the most valuable sources of history for the Saracen empire. It has been edited and translated into Latin (5 vols. 1789-94) by Reiske; the earlier part, *Historia antislamica*, by Fleischer (1831). His other great work is his famous *Geography*.

Abushehr. See BUSHIRE.

Abu-Simbel (also *Abusambul* or *Ipsambul*), a place on the left bank of the Nile, in Lower Nubia, the site of two very remarkable rock-cut temples, amongst the most perfect and noble specimens of Egyptian architecture. Here there is no exterior and constructed part; the rock out of which they have been excavated rises too near the river. Still the temples have their façade, as richly decorated and as monumental in its character as those of the most sumptuous edifices of Thebes. The colossal statues here, instead of being isolated monoliths, are a part of the façade itself, hewn out of the rock, though still forming part of

it. The façade of the smaller temple, that of Hathor, is 88 feet long and 39 feet high. It has six colossal figures, about 32 feet high, of which four represent Rameses, and the other two his wife, Nefert-Ari. The façade of the great temple is larger, being 126 feet long and 93 feet high. The cornice is formed by twenty-two dog-headed figures seated, the fore-paws resting on the knees, each 8 feet high, sculptured in relief, only attached to the mountain by their hinder parts. Below the cornice runs a frieze formed by the dedicatory inscription, engraved deeply in bold hieroglyphics. Above the door is sculptured a colossal figure of Râ, on both sides of which Rameses is represented in the attitude of adoration. Most striking, however, are the four colossal figures of Rameses, two to the right, two to the left of the door. These are the largest figures of Egyptian sculpture, being

Façade of the Great Temple at Abu-Simbel.
(From a Photograph by Firth.)

66 feet high from the feet to the *pschent* with which the king's head is covered. Rameses is seated, his hands resting on his thighs, in the ordinary posture of royal statues at the entrance to temples. In spite of its enormous proportions, the work is very fine; the face especially is remarkable for an expression of sweetness and of strength in repose that has struck all travellers. The depth of the smaller temple from the door is 88 feet. The great temple is much larger, being 180 feet long from its threshold to the innermost part. The first hall is 59 feet long and 55 feet wide. The second and third are less spacious. The fourth, the adytum, consists of three chambers. Everywhere are pictures like those at Luxor and Karnak, representing the battles and the triumphs of Rameses.

Abydos, (1) a town in Asia Minor, on the narrowest part of the Hellespont, opposite Sestos, celebrated as the place whence Xerxes (q.v.) passed into Europe in 480 B.C.; and in poetry on account of the loves of Hero (q.v.) and Leander.—(2) A ruined city of Upper Egypt, capital during the 1st and 2d dynasties. Here are the remains of the Memnonium and of a temple and tomb of Osiris, with a great reservoir of the oldest period of Egyptian architecture, and tombs of the 7th and 8th dynasties. See EGYPT (*Religious Monuments*).

Abyla. See CEUTA.

Abyssinia, the modern representative of the ancient Ethiopia, is an interesting country inhabited by a curiously interesting people. The consolidation of the kingdom just after the middle of the 19th century by Theodore, an Amharan ruler, and his tragic death in war with Britain in 1868; the successes of the next king John, a prince of Tigré, against the Egyptians, and his fall in the great victory of Gallabat, won over the Dervishes in 1889; the great extension of the kingdom and of its power under the crafty and persevering Menelek (Menilek, Menelik; 1842-1913) of Shoa, who, compelled for a time to accept what the Italians regarded as an Italian protectorate, secured again the complete independence of his country when an Italian army was annihilated by one of his generals on the bloody field of Adowa—all this has made Abyssinia vastly more important in the eyes of Europe and America. Menelek's friendship and favour were assiduously cultivated by Russia, France, and the United States, as well as by Britain; and Britain has had to congratulate itself on the co-operation of Abyssinia against the 'Mad Mullah' in Somali-land. To the old provinces of Amhara, Tigré, and Shoa, still the essential part of the country, have been added the two provinces of Gojam and Harrar, while the boundary has been shifted indefinitely towards south to south-east. Addis Abbaba (Adis Abeba), in Shoa, is now the capital. The dominant race (see below) is not precisely the same over the whole area; but the Abyssinians, though their dark skin indicates a large admixture of native African blood, insist that they are of Semitic blood, as their speech is undoubtedly Semitic. Hence they detest the name *Abyssinia*, derived from their own word *habesh*, 'mixture.' Their own name for themselves is Itiopavian or Ethiopian. Semi-savage, and in some things wholly savage, they are yet fanatically Christian; also, Abyssinia is now the only wholly independent native state in Africa.

The Switzerland of Africa, Abyssinia occupies a very mountainous part of the upper valley of the Nile to the south-west of the lower end of the Red Sea, but extends over the watershed toward the Indian Ocean, and lies mainly between the Egyptian Sudan and the Italian coast strip of Eritrea (see map at AFRICA). Its glorious mountain scenery has been the seat of tremendous volcanic activity. The chief divisions are still Tigré in the north, Amhara in the centre, and Shoa in the south. Between the highlands and the Red Sea lies a low arid tract, which is inhabited by tribes distinct from the Abyssinians, and long claimed as belonging to Egypt. Abyssinia, the area of which is about 350,000 sq. m. (including Abyssinian Somaliland), consists of a huge tableland with a mean elevation of 7000 feet. The declivity to the bordering tract on the Red Sea is abrupt; towards the Nile basin it is more gradual. The main mass has been cut into a number of island-like sections by the streams, which have worn their channels into ravines of vast depth—as much sometimes as 4000 feet. Isolated mountains, with naked perpendicular sides, present the most singular forms. The Simen Mountains have summits rising to the height of 15,000 feet.

In the later part of the tertiary age, Abyssinia must have been the theatre of immense volcanic activity. That activity is now extinct, with the exception of thermal springs in the interior, and rare eruptions on the coast of the Red Sea.

As the main slope of the tableland is towards the W. and NW., the chief watercourses flow to the Nile. The Abai, which flows through Lake Tzana, is an upper branch of the Blue Nile. The Takazzé, receiving the smaller Atbara, joins the Nile under

the name of the Atbara, after a course of about 800 miles. The Mareb flows NW. into Nubia, where it loses itself in the sand, or in time of flood reaches the Atbara. The Hawash takes its rise in the southern province of Shoa, and flowing in a north-easterly direction, falls into the Lake of Abhebbad. The largest lake in Abyssinia is Lake Tzana (Tsana) or Dembea, 60 miles long, and in some places 600 feet deep. The mineral wealth of Abyssinia is believed to be great, but has been little explored.

The climate of Abyssinia, notwithstanding its tropical position, is on the whole moderate and pleasant owing to its elevation. The region called the Kollas, with an elevation of 3000 to 4900 feet, has a temperature of 77° to 95°, with a tropical vegetation. The plains of medium elevation (5000 to 8800 feet) have a temperature of 60° to 80°, and are the chief seats of the population. The higher regions, from 8800 to 12,000 feet or over, have usually a day temperature of 48° to 50°, but falling not seldom below freezing. The rainy season is in summer, from April to September. During the rainy season there is snow on the summits in all the higher regions, and above 13,000 feet the snow never melts. In the river valleys and swamps, the heat and moisture are suffocating and pestilential; in the low region towards the Red Sea, the air is glowing hot, and dry.

Abyssinia as a whole is exceedingly fruitful; and its productions are of the most varied nature, from the pines, heaths, and lichens of North Europe to the choicest tropical plants. Two, and in some places three, crops can be raised in one year. The banana-tree, date-palm, sugar-cane, vine, orange, lemon, cotton, and wild indigo and coffee, all flourish. The higher plateaus furnish rich pastures of European grasses, and also oats and barley. The chief industries are the rearing of cattle and the cultivation of grain. Among the wild animals the most dreaded is the hyena; while the elephant and rhinoceros are found in the low grounds, and there are crocodiles and hippopotami in the rivers. Lions, panthers, and leopards are not infrequent.

The population of Abyssinia, which numbers between four and five millions, consists of various elements, but the nucleus is formed of the Abyssinians proper—a brown, well-formed people, belonging to the Semitic stock, and believed to be the descendants of immigrants from Arabia. The basis of the language is the ancient Ethiopic (see ETHIOPIA) or Geez, a Semitic tongue which is now the sacred language, understood only by the priests. Of the modern dialects, the Tigré of the northern province stands the nearest to the old tongue. That of Amhara (q.v.), spoken also in Shoa, departs more from the mother-tongue, and is the prevalent language of the country. Since the beginning of the 16th century, the Gallas, an African people, have taken possession of many districts. Jewish tribes, called Falashas, retain many of their Jewish peculiarities. In addition to agricultural and pastoral pursuits, the chief employments are the preparation of leather, the weaving of cotton cloth, and the working of copper and iron. There is little commerce. What foreign commerce there is passes through the ports of Massowah and Zela. The chief town of Tigré is Adowa. Gondar in Amhara, and Ankobar in Shoa have decayed. The capital of Shoa and of Abyssinia is Addis Abeba.

The religion of the Abyssinians' proper is a debased Christianity; but the Gallas and other alien tribes are mostly Mohammedan, and partly also pagan. Abyssinian Christianity consists entirely in external observances; the people are abjectly superstitious and excessively lax in their morals. They observe many of the rites of

Judaism, such as circumcision and the distinction of animals into clean and unclean. The marriage-tie is very loose, and polygamy is not uncommon. Few except the priests are taught to read. Christianity was introduced in the 4th century by Frumentius (q.v.), who was consecrated Bishop of Abyssinia by the Patriarch of Alexandria. Ever since, the church of Abyssinia has adhered to the mother-church of Egypt, and with her adopted the Monophysite (q.v.) doctrine; and the metropolitan bishop or abuna continues to be nominated by the Coptic Patriarch (see COPTS). The Bible was early translated into the Geez. They have no other literature except some legends of saints. The general ignorance does not exclude religious controversy, and fierce dissensions prevail. There are numerous fasts and feast-days. Drinking (of beer and mead) is carried to excess. Beef is eaten raw, and, if possible, while yet warm. The custom reported by Bruce, of cutting a steak from a live cow, is still not unknown.

History.—The native annals of Abyssinia, tracing their kings from Menilek, the son of Solomon by the Queen of Sheba, down to recent times, are manifestly fabulous. The real history begins with the kingdom of Axum (see AXUM, ETHIOPIA). Christianity was introduced in the 4th century. Under the Axumite rulers, Abyssinia attained its greatest extent and prosperity in the 6th century, when it embraced Yemen in Arabia. But by the conquests of the Mohammedans in the following century, the frontiers were driven back to the limits of the tableland, and the Abyssinians were cut off from intercourse with the rest of the world. During these struggles the capital was removed from Axum to Gondar, where the monarchs dignified themselves with the title (assumed about the end of the 13th century) of Negusa Nagast za-Itjopja (king of kings of Ethiopia). With the 16th century began the irruptions of the warlike Galla tribes from the interior of the continent, who committed fearful devastations. The search for the kingdom of Prester John (q.v.) brought the Portuguese in contact with Abyssinia in the end of the 15th century. The design was thereupon formed of converting the Abyssinians to the Catholic Church. With this view an embassy was sent to the Negus (1520); and at last, about the beginning of the 17th century, the royal family submitted to the Roman Church. The body of the people, however, looked upon it with aversion; and in 1634, the monarch was obliged to resign in favour of his son, who banished or executed the Catholic priests.

The monarchs lost all control over the great chiefs, who set up as independent rulers in their several provinces. At length Michel Sohul, the ruler of Tigré, put the reigning monarch Juas to death (1769), and setting up a member of the royal family as nominal sovereign, exercised at Gondar the powers of sovereignty under the name of *Ras* or prime minister. *Ras* Michel was soon driven from power by a Galla chief, who acquired the dominion of Amhara and the control of the titular sovereign, and transmitted his power to his son and grandson. The latter, *Ras Ali*, held sway in Amhara as viceroy of the empire, when, about 1850, the adventurer Kasa or Kassai, afterwards known as Theodore, began to excite attention. Kassai was a native (born 1816) of Kuara, a province in the west of Amhara, of which his uncle was governor. After the uncle's death, Kassai, defeating the armies of the *Ras*, compelled his recognition as governor, and became *Ali's* son-in-law. In 1853 he crushed the *Ras*, and two years later, after completely defeating the prince of Tigré, he had himself crowned by the Abuna as Negus of Abyssinia, with the name of Theodore. He then subdued the Wollo Gallas; and having

next conquered Shoa, he was now master of the whole of Abyssinia, and with greater power than was ever wielded by a Negus. This was the acme of his fortunes, which henceforth began to decline. At first he ruled prudently and with moderation, being chiefly guided by two Englishmen, Mr Plowden and Mr Bell, who had become resident in the country, and the former of whom had been appointed consul. But after he lost his two counsellors (who were killed in an attack by a rebel chief in 1860), his rule became more and more tyrannous. The enormous army (as many at one time as 150,000 out of a population of 3 or 4 millions) exhausted the resources of the country. One province after another rose in rebellion, unable to bear the exactions; and these insurrections were suppressed with unheard-of rigour.

Theodore had made several attempts to procure the active alliance of England and France against the Mussulman powers; and as all his efforts had failed, he now began to entertain hatred towards Europeans. When Captain Cameron went to Abyssinia in 1862 as consul, Theodore gave him a letter to Queen Victoria, of which, by some neglect, no notice was taken. A similar letter to the Emperor of the French received an answer, but not from the Emperor himself; and these circumstances so enraged Theodore that he began to maltreat the consuls and their servants, and kept them prisoners along with the missionaries and other Europeans in his dominions. The British Government in 1864 sent envoys to Theodore with a royal letter and presents, to treat of the release of the prisoners. The negotiations failed, and the three envoys were put in irons, and shut up along with the other prisoners in the fortress of Magdala. A British military expedition was now resolved upon, and General (afterwards Lord) Napier was chosen as chief. The troops consisted of 16,000 men of all arms, while the transport service and camp-followers numbered at least as many more. The place of landing was Annesley Bay, and on the 9th April 1868 they reached Magdala. They had met with no obstruction from the inhabitants, who rather welcomed them as deliverers from the common enemy. In the meantime, Theodore had occupied the fort with 5000 or 6000 men, three weeks before the arrival of the British. On the 10th April, 5000 Abyssinians rushed down upon a British detachment of 1700 men in the plain below the fort, but their repeated assaults were repulsed with great loss. Theodore sued for peace, and released the prisoners; but as he declined to surrender, the fort was stormed and taken on the 13th. Theodore was found dead—he had shot himself. The fort being demolished, the British forces were entirely withdrawn.

The departure of the British was the signal for a renewed struggle. Kassai of Tigré vanquished his most powerful rival, and had himself crowned Emperor of Abyssinia in 1872, assuming the name of John. He made repeated but vain attempts to get European help against the Egyptians, with whom Abyssinia had been at enmity since 1860. In 1875 there was a bloody but short and indecisive war between the Khedive's forces and the Abyssinians; and frontier difficulties continued until the Soudan was evacuated by Egypt in 1882. In 1885 the Italians occupied Massowah. On the death of John in 1889, Menelik, king of Shoa, became Negus of Abyssinia, and by treaty Italy took over all foreign relations. But Menelik was a restive vassal; and in February 1896 an Italian expedition was utterly defeated by Menelik near Adowa, the survivors of the Italian army being captured. The treaty of November 1896, which released the Italian prisoners, acknowledged the complete independence of Abyssinia. Italy retained only the coast strip; Kassala was

given to Egypt in 1897; in 1898 the Negus ceded 8000 miles of Somaliland to Britain; in 1906 an agreement was signed with France and Britain as to boundaries and railways. Menelek died in 1913. His grandson, Lidj Yasu, was deposed in 1916, and Menelek's daughter, Zeodita, succeeded. Abyssinia entered the League of Nations in 1923.

Smith (1890), Portal (1891), Munzenberger (1892), Bent (1893), Prince Henri d'Orleans (1898), Gleichen (1898), Roux (1901) Wyde (1901), Michel (1905), Skinner (1906), Gilmour (1906), Rey (1923).

Acacia, an important genus of leguminous trees or shrubs, of the sub-order Mimosæ, mainly natives of tropical Africa or Australia, frequently

Fig. 1.—Acacia (*A. arabica*).

thorny, with extraordinary differences in general appearance, owing to the remarkable modifications of the vegetative organs. The normal type of leaf is bipinnate (fig. 1); but is often modified, especially among the species which have had to become adapted to the intense heat and drought of Australia, where they greatly abound, forming 'acacia-scrub.' The leaf-blade entirely ceases to be developed, and the leaf-stalk becomes 'vertically flattened into a 'phyllode,' which thus resembles a

Fig. 2.

Fig. 3.

Fig. 4.

simple leaf, and performs vegetative functions; but, like the leaves of many species of Eucalyptus, presents only its edge to direct sunshine; and by its thick and strong epidermis is further adapted to resist transpiration. The line of modification is beautifully indicated by such a species as *Acacia heterophylla* (fig. 2), in which, along with the

as *A. acia alata*, where even the phyllodial type becomes disguised by the downward continuation of the phyllode into an expanded wing running down the stem, somewhat like the decurrent leaves of a thistle (fig. 4). Many species are also cultivated in our greenhouses for the sake of their flowers, which are united into golden stamen-tufts of great beauty, and are often fragrant. The leaves often exhibit Sleep-movements (q.v.) analogous to those which are developed into sensitiveness in some of the allied Mimosas (see SENSITIVE PLANT), and in some species close whenever the sun is clouded. The genus is also of great and varied economic importance, not merely as frequently yielding timber or edible seeds in the regions where they flourish, but as possessing the astringent and gum-yielding properties common in the sub-order in the highest degree. The drug known as Catechu (q.v.) is prepared from *Acacia catechu*; while of still greater importance are the products yielded by the degeneration of the cell-walls of the inner bark (bast-parenchyma and sieve-tubes). These substances are known in commerce as Gum-Arabic, Gum-Senegal, &c., and are obtained from *Acacia arabica*, *Acacia senegal*, and other species (see GUM). Some species of Robinia, such as the North American locust-tree (*R. pseud-acacia*), *R. hispida*, Rose acacia, &c.—are often erroneously called acacia in Europe and the United States, sometimes also thorn-acacia (a false acacia), but belong to a distinct sub-order of Leguminosæ, the Papilionaceæ, having violet, pea-like flowers. *Flores Acaciæ* is an old medical name for sloe-flowers.

Academy (Gr. *akadēmeia* or *akadēmia*) was the name of a public park nearly a mile to the NW. of Athens, equipped as a gymnasium by Hipparchus, and bequeathed to the citizens as a pleasure-ground by Cimon, son of Miltiades, who had adorned it with avenues of trees, statues, and altars. In its shady walks (the 'groves of Academe') Plato was wont to converse with his disciples and friends; and so the name of the meeting-place, said to have been originally derived from the hero Academus, came to be used as a distinctive title of Plato's school and of the Platonic philosophy. The various phases of development or perversion which Plato's principles underwent at the hands of a long train of successors are spoken of as the *Old Academy*; the *Second* or *Middle Academy*, led by the disputatious Arcesilaus (q.v.); and the *New Academy*, of which the sceptical Carneades (q.v.) was the head. Occasionally the professedly Platonic system, as taught by Philo and Antiochus respectively, is referred to as the Fourth and Fifth Academies. Cicero's *Questiones Academicæ* had their name from one of his villas known as *Academia*. At the revival of classical studies in the 15th century, the name academy came to be given in Italy either to associations of learned men or to educational institutes, and a like divergence still marks the use of the term. In Germany it is generally used of learned societies, is occasionally applied to the universities, and is the recognised denomination of many technical institutes, such as military and naval academies, schools of mining, agriculture, and forestry. In Britain and America academies may be grammar-schools, military and naval educational schools, or associations for the promotion of music and the fine arts. Sometimes 'academy for young gentlemen' is simply an elementary boarding-school. France is divided for educational purposes into seventeen circumscriptions or territorial areas called *académies*, with rectors, academic councils, and inspectors; these together form the University of France. The *Académie* of Geneva is its university. The Grand Opera in Paris is officially, but strangely, termed *Académie Nationale de Musique*, an example followed by several of the

comic theatres. In America (as at New York, &c.) the name Academy of Music is often used of operahouses.

In its most universal modern acceptation, the word academy denotes a society of learned men, incorporated for the promotion of science, literature, or art. The first institution in ancient times that seems to merit the name, in this sense, of academy was the celebrated *Museum* founded at Alexandria in the 3d century B.C. by Ptolemy Soter, which concentrated in that intellectual capital all that was most eminent in science, philosophy, poetry, and criticism. After this model, the Jews, and at a later period the Arabians, founded numerous institutions for the promotion of learning. In the middle ages, with the exception of the Moorish institutions at Granada and Cordova, in which poetry and music formed prominent subjects of study, we find nothing corresponding to the modern idea of an academy, save the learned society established by Charlemagne in his own palace, at the suggestion of his teacher Alcuin. In the following centuries there are no traces of any like associations; during the middle ages such learning and science as survived had taken refuge within the monasteries. The academy of the fine arts founded at Florence by Brunetto Latini in 1270, that by Frederick II. at Palermo in 1300, and the *Académie des Jeux floraux* at Toulouse in 1323 existed solely for the culture of poetry. Not till the revival of classical studies in the 15th century did those associations of learned men arise which soon accomplished so much for promoting a freer development of human thought, in opposition to the narrowness of ecclesiastical tradition and monastic practice. The *Accademia Platonica* of Florence, established by Lorenzo de' Medici in 1474, devoted itself not only to the investigation of the Platonic philosophy, but to the purification of the Italian tongue and the study of Dante, thus becoming the model of many like institutions in all the more important Italian cities, though it was itself dissolved in 1521. The *Accademia della Crusca*, or *Accademia Purgatorio*, was founded at Florence in 1582; its principal service was the compilation of an excellent dictionary, and the publication of correct editions of the older Italian poets. The Neapolitan *Accademia Secretorum Naturæ*, founded in 1560 for the prosecution of the physical sciences, was the first of its kind, but was speedily suppressed by the church. Among the many associations upon its model were the short-lived *Accademia de' Lincei* in Rome (1609), and the *Accademia del Cimento* at Florence (1657). All these and their numerous sister academies in Italy were independent associations, occasionally patronised by princes, but not recognised or formally sanctioned by the state.

A new development was given to such bodies when, in 1635, Richelieu transformed a private association of poets of no great note into a national institution, the *Académie Française*. Its chief object was to give exact rules to the French language, and render it elegant, pure, eloquent, and capable of treating the arts and sciences; and it pledged itself to compose a dictionary, a grammar, and treatises on rhetoric and poetry. The great dictionary, much criticised then and since, was published in 1694, and reached its 7th edition in 1878. A historical dictionary was also undertaken at Voltaire's instigation, but was abandoned (1894) after the publication of 4 vols. devoted to the letter A. The influence of the Academy on the French language and literature has naturally been in the main conservative, and directed on 'taste' rather than on originality. It boasts on its roll of members most of the eminent French writers, though *entre autres* it failed to elect Descartes (who lived abroad),

Pascal, Molière (as a player), La Rochefoucauld, and Lesage (who refused nomination), Saint-Simon, Jean Jacques Rousseau, Diderot, Beaumarchais, Honoré de Balzac, Béranger (who also declined), and Zola or any woman writer. Louis XIV. founded the *Académie des Inscriptions* in 1663 for the immediate object of examining his collection of medals and other antiquities. The third academy in order, the *Académie Royale des Sciences*, was founded by Colbert in 1666. The painter Le Brun founded in 1648 an *Académie de Peinture*, for which he obtained a charter in 1655; and in 1664 Colbert remodelled and established it as the *Académie Royale de Peinture et Sculpture*, with which was afterwards incorporated the *Académie Royale d'Architecture*, founded 1671. All these academies were suppressed by an edict of the Convention (1793); but in 1795 the Directory established a great national association, for the promotion of the arts and sciences, called the *Institut National*. It was at first divided into three classes, and rearranged in four in 1803. In 1816 Louis XVIII. restored the names of the old academies to the four classes of the Institute—(1) *L'Académie Française*; (2) *L'Académie des Inscriptions et Belles-lettres*; (3) *L'Académie des Sciences*; (4) *L'Académie des Beaux-arts*, the general title, 'Institut de France,' becoming successively modified by the epithet 'Royal,' 'Impérial,' or 'National,' in harmony with the political changes in France. An ordinance of 1832 re-established the old second class as a fifth academy, *L'Académie des Sciences Morales et Politiques*. Each academy has its own jurisdiction and work; the library and valuable collections of the *Institut* are common to the five. Since 1807 the *Institut* has been housed in what was the Palais Mazarin or Collège des Quatre-Nations. Members are elected by ballot, the election requiring confirmation by government. Members of one academy may belong to any or all of the other four. Every member gets a small annual allowance, and the six permanent secretaries of the five academies (the *Académie des Sciences* has two) receive moderate salaries. Each academy appoints two members to a Central Commission of Administration. The *Académie Française* has a director and a chancellor, changeable every three months. All five academies hold weekly meetings; the *Institut* meets once annually for each academy, and there is a general public session of the whole *Institut* on 25th October, the anniversary day of its foundation. From the outset the number of *fauteuils* (seats) for the 'Immortals' of the *Académie Française* has been limited to forty. The membership of the *Académie des Sciences* is sixty-eight, of the *Académie des Beaux-arts*, forty-one; the others have each forty members. With the exception of the *Académie Française*, each academy has ten *académiciens libres*, a few *associés étrangers*, and numerous *correspondants*; 'académiciens libres' have only the right of attending meetings of the academy; 'associés étrangers' are foreign members. In 1654 a prize for eloquence was founded by bequest of Balzac, and its first award in 1671 inaugurated the laureate system of the *Académie Française*. The *Institut* now administers large funds, and its component parts distribute many prizes for distinction in various fields—e.g. the Montyon (q.v.) prize. The *Académie de Médecine* (created 1820, in place of the Royal Academy of Chirurgery and Royal Society of Medicine, 1731-93) is not part of the *Institut*; its membership is a hundred. The *Académie Goncourt* (ten members), formed in 1903 in terms of the will of Edmond de Goncourt (q.v.), awards an annual prize to a writer of fiction.

See *L'Institut de France*, by A. Franklin and others (1907); *Le Premier Siècle de l'Institut*, by Comte de Franqueville (1895); and the *Annuaire* of the *Institute*;

histories of the *Académie Française*, in French, by Pellisson and D'Olivet (1743; reprinted 1858), P. Mesnard (1857), E. Gassier (1906), G. Boissier (1910), and F. Masson (1913), and in English by D. M. Robertson (1910).

Academies after the Parisian model were soon established in most of the other European capitals. Of these several have attained the rank of national central institutions, as those of Madrid, Lisbon, Stockholm, and Petrograd. Centralisation of this kind has never been possible in Italy, Germany, or England, where the advantages and disadvantages of such academies have often been discussed, notably by Matthew Arnold in his essay on the *Literary Influence of Academies*. In 1899 an *International Association of Academies* was founded 'for the preparation and promotion of scientific undertakings of general interest, and to facilitate scientific relations between different countries;' it holds triennial congresses, attended by delegates representing academies and learned societies throughout the world. Whether working with the sanction and support of the state or as independent associations, academies, when not directly modelled after the French Institute, generally fall into two or three main classes or departments, of which one at least interests itself in mathematics and the natural sciences; another is devoted to philosophy, philology, and history. The members, who in many cases receive a salary, are usually classified as *ordinary*, *honorary*, and *corresponding*. They may choose each for himself a special subject of research, or, as in Petrograd, have one assigned to them by the government. The results of their labours in their various departments are reported at the regular periodic sittings, and thereafter published by the academy. These papers are in England generally termed *Transactions* (Lat. *acta*, or *commentarii*; Ital. *atti*; Fr. *mémoires*); shorter papers, reports of the sittings, notices to members, correspondence, and the like appear in the form of a journal, and are commonly known as the *Proceedings* (Fr. *bulletins*, *comptes rendus*). Prizes are customarily established by the academy for work upon new or difficult subjects.

In France numerous learned societies in the provinces bear the name of *Académie*.—Spain possesses the *Real Academia Española*, founded at Madrid in 1713 for the improvement of the Castilian language; an academy of history (1738); and another (1847) for the furtherance of mathematics and natural science (*Real Academia de Ciencias Exactas*).—The Portuguese Academy was founded in 1779. In Italy, besides the already-mentioned *Crusca*, and the *Del Cimento* at Florence, valuable services have been rendered by the Academy of Sciences at Turin, a private association from 1757 till 1783, when it became a royal institute; the academies at Milan (1838), at Venice (1838), at Padua (1779), at Brescia (1801), and Bologna (1712); the *Società Italiana delle Scienze* at Modena; at Rome the *Accademia degli Arcadi* (1656), the *Accademia de' Nuovi Lincei* (1847); the agricultural *Accademia dei Georgofili* (1752) at Florence; and the Neapolitan *Nuova Società Reale*.

The *Académie der Wissenschaften* of Berlin was founded in 1700 by Frederick I. The first president was Leibniz. Under the great Frederick, new life was infused into the academy by the encouragement offered to learned men of all countries to settle at Berlin. Maupertuis was now appointed president, and the academy was reorganised under the four classes of Physics, Mathematics, Philosophy, History and Philology. The famous *Gesellschaft der Wissenschaften* at Göttingen has been in existence since 1752. The academy at Munich dates from 1759; that at Leipzig from 1768.—The Austrian *Académie* at Vienna was instituted in 1847.—Notable also are societies at

Prague and Cracow, and the Hungarian academy at Budapest.—In Belgium the *Académie Royale* (1772, 1808) holds the first rank.—The Netherlands have an *Académie van Wetenschappen* (1808); besides learned societies at Middelburg, Utrecht, Haarlem, and Rotterdam.—The national academy of Denmark has published valuable transactions since 1742.—Norway has had an academy at Trondhjem since 1760, and another in Christiania since 1837. Sweden possesses two academies at Stockholm for the promotion of science and literature, founded respectively in 1739 and 1786; besides the well-known *Regia Societas Scientiarum* of Uppsala.—The Petrograd academy was planned in 1724 by Peter the Great, but founded by Catharine I. in 1728. Finland has a *Societas Scientiarum*, meeting at Helsingfors.—There are a Serbian academy at Belgrade and a Rumanian one at Bucharest. Constantinople instituted one in 1851, and there is one at Alexandria.

In Great Britain learned associations are most frequently known as Societies (q.v.). The *Royal Society*, the *Royal Society of Edinburgh*, and the *British Association* are treated in separate articles. Except in the case of the *Royal Irish Academy of Sciences* in Dublin (founded 1782), and the *British Academy* for the promotion of historical, philosophical, and philological studies (which received a royal charter in 1902), the name academy is in Britain generally reserved for institutions for the cultivation of the fine arts; see ROYAL ACADEMY. An 'Academic Committee' to consist of forty members was organised in 1910 by the Royal Society of Literature and the Society of Authors; it is designed, like the French Academy, to maintain the purity of the English language, encourage fellowship amongst its members, and arrange 'discourses of reception,' obituary addresses, and the awarding of medals. The *Royal Scottish Academy* of Painting, Sculpture, and Architecture was founded at Edinburgh in 1826, and received a royal charter in 1838. Similar to these also is the *Royal Hibernian Academy*, incorporated at Dublin in 1803. The *Royal Academy of Music* in London (1823) is an educational institute.

In America, as in Britain, learned societies are not usually termed academies (e.g. the *Smithsonian Institution* at Washington, q.v., and the *American Philosophical Society* at Philadelphia, 1780), but some are. The *American Academy of Arts and Sciences* was established at Boston in 1780; it had previously existed in another form, the original institution being due to Franklin. The *Academy of Natural Sciences* was founded at Philadelphia in 1812. The *Connecticut Academy of Arts and Sciences* was organised at Newhaven in 1799. The *New York Academy of Sciences* was incorporated in 1818 as the 'Lyceum of Natural History.' The *National Academy* was incorporated by the congress of the United States in 1863, its object being to examine and report upon scientific questions. The *Academy of Science of St Louis*, Missouri, was incorporated in 1857. The *Chicago Academy of Science* (1865) publishes occasional Transactions. The *Academy of Political and Social Science of Philadelphia*, founded in 1889, is notable in its special lines of research. The *Pennsylvania Academy of Fine Arts*, at Philadelphia (1805), affords excellent facilities for instruction. The *National Academy of Design*, in New York, claims to be the foremost school of art in the United States; and the art schools at St Louis, Cincinnati, Chicago, &c. are virtually academies of the fine arts.—Canada has its *Royal Society* (1882); whilst at Rio Janeiro and other South American capitals there are academies of literature, science, and art. Some of the great Military Schools (q.v.) are also called academies—notably West Point (q.v.).

Acadia (*Acadie*; Micmac *Akâde*, 'abundance'), a name given by the French settlers to Nova Scotia (q.v.) on its first settlement in 1604, and ultimately extended to comprise New Brunswick and part of Maine. When a grant of the peninsula was obtained in 1621 by Sir William Alexander, it was named Nova Scotia in the charter. His attempts to colonise the country on a large scale were defeated by the French. The English claimed the colony by right of discovery—as having been discovered by the Cabots; the exclusive possession of the fisheries proved a further bone of contention. In 1667 it was ceded to France; but the English colonists never recognised the cession, and harassed the French settlers. In 1713 France gave up all claim to the colony: the Acadians mostly remained, though they had liberty to leave within two years, and were exempted from bearing arms against their brethren. A French settlement was formed on Cape Breton, and received the name of Louisbourg; whilst as a result of French intrigues with the Indians, the latter harassed the English. The majority of the Acadians would not take the oath of allegiance, nor would they refrain from abetting underhand hostilities against the English. 'The French government,' says Parkman, 'began by making the Acadians its tools, and ended with making them its victims.' Accordingly, in 1755 it was determined at a consultation of the governor and his council to remove them; and to the number of about 18,000, they were dispossessed of their property and dispersed among the other British provinces. This wholesale expatriation, often severely condemned, was not resorted to until every milder resource had been tried. A simple, yet very ignorant peasantry, living apart from the rest of the world, they were ruled by the priest, who taught them to stand fast for the church and King Louis, and to resist heresy and King George. The sufferings of the Acadians form the groundwork of Longfellow's *Evangeline*. See Murdock's *History of Nova Scotia* (1866); Hannay's *History of Acadia* (1879); and Parkman's *Montcalm and Wolfe* (1884).

Acajutla, a small seaport on the west coast of San Salvador, which still has considerable trade, but was formerly much more prosperous.

Acalephæ (Gr., 'nettles'), a term first applied by Aristotle to the jelly-fish tribe, on account of their stinging powers. At a later period the designation was used by Cuvier and others to include the true medusæ or jelly-fishes, Acraspeda (q.v.), the Lucernaria, and the Ctenophora (q.v.), while others have given it a still wider application equal to Cœlenterata. The term has now been replaced by a more precise nomenclature. See CœLENTERATA, HYDROZOA, and JELLY-FISH.

Acanthocephala, a peculiar order of parasitic worms, of cylindrical form, with protrusible hook-bearing proboscis, and without alimentary canal. The order includes a few genera, of which the best known is *Echinorhynchus* (q.v.).

Acanthopterygii, a term due to Cuvier, and

Perch, an Acanthopterygious Fish.

employed to designate one of the principal orders

of bony fishes (see FISHES). Literally meaning thorny-winged (Gr. *acantha*, 'a thorn,' and *pteryx*, 'a wing'), the term describes one of the characteristics of the order—namely, the presence of unjointed spinous rays in the dorsal, anal, and ventral fins. Among the common representatives are perch, mullet, mackerel, miller's thumb, gurnard, blenny, and stickleback.

Acanthus, the name given by the Greeks and Romans to the plants sometimes also called Brancursine, and adopted by Linnæus as the generic name. *Acanthus spinosus* and *Acanthus mollis*, natives of the south of Europe, are the species best known, and are of considerable interest as having been more largely conventionalised in

Acanthus spinosus, natural. Ornamental Acanthus Leaf.

sculpture and decoration than any other plant. *Acanthus mollis* is said to have furnished to Callimachus the idea of the Corinthian capital. The adherence to this form is simply traditional, since numberless other plants lend themselves equally well to the purposes of the designer. The genus *Acanthus* is the type of the Acanthaceæ, a sympetalous dicotyledons, allied to Scrophulariaceæ, chiefly tropical, and of no important properties. The majority are mere weeds, but several genera are valued hothouse flowers.

Acapulco, the best Mexican harbour on the Pacific, situated about 180 miles SW. of the capital. The harbour is so well sheltered that 500 vessels may ride safely at anchor close to the granite rocks. The climate is hot and unhealthy, and earthquakes (as in 1909) are not infrequent. The chief exports are cochineal, indigo, cocoa, wool, and skins; the imports are cottons, silks, spices, and hardware. Pop. about 5000, mostly Indian half-breeds.

Acarina, or mites, in the wide sense, form a low order of Arachnida (q.v.). Most of them are extremely small, the body is all one piece, the mouth parts are modified for sucking or biting, and the organs are generally simple and often degenerate. There are usually four pairs of legs, but these are often reduced. They are very prolific, and they always show some metamorphosis. Of universal distribution, they occur especially where food is abundant—e.g. in decaying animal and vegetable matter, or within and upon other organisms. Many of them form galls on plants. The Cheese-mite (q.v.), the Sugar-mite, the Itch-mite (see ITCH), the common Harvest-mite (q.v.), the frequent parasite on the

Cheese-mite.

human nose (*Acarus folliculorum*, q.v.), the abundant ticks, the water-mites on water-beetles, &c., the familiar 'red spider' of hothouses, are exceedingly frequent forms. An East-Indian harvest-mite (*Trombidium tinctorum*) yields a dye. In their destruction of decaying organic matter, mites doubtless act as beneficial scavengers. Some acarina—e.g. ticks—disseminate the germs of disease, such as Texas fever in cattle. As abundant and troublesome parasites they are of some importance.

Acarnan, one of the Epigoni, son of Alcmaeon (q.v.) and Callirrhoe, with his brother Amphoterus avenged his father's death. He was reputed to be the founder of the state of Acarnania.

Acarnania, the most westerly part of ancient Greece, separated from Epirus on the N. by the Ambracian Gulf, now the Gulf of Arta; from Ætolia on the E. by the river Achelotus; and washed S. and W. by the Ionian Sea. Its inhabitants were brave, but rude and addicted to piracy and robbery. Along with Ætolia, it now forms one of the provinces of the modern kingdom of Greece. The western part of Acarnania is occupied by a mass of rocky and thickly-wooded mountains rising abruptly from the indented coast. Among the inhabitants, besides the Greeks, are bands of nomadic Kutzo-Wallachs called *Karagunis* ('black-cloaks'), who descend from the mountains at the approach of winter, and squat with their herds at the edge of the woods. The chief town is Missolonghi.

Acarus folliculorum, or DEMODEX FOLLICULORUM, is a microscopic parasite allied to the mites, which inhabits the hair-follicles and sebaceous glands of the human skin, also the wax of the ear. It is found most commonly in the skin of the nose, and is present in a large proportion of healthy individuals, but is of no practical importance. It may be seen when present by squeezing out the contents of a sebaceous follicle, mixing with a little oil on a glass slide, and examining under the microscope. It is from $\frac{1}{16}$ to $\frac{1}{8}$ inch in length. The thorax occupies from $\frac{1}{4}$ to $\frac{3}{4}$ of its length, and is furnished with four pairs of rudimentary limbs. See PARASITES.

Acarus folliculorum.

Acca. See ACRE (ST JEAN D').

Accad, or AKKAD, was the northern division of ancient Babylonia, as distinguished from Sumer, the southern. The Accadians were the dominant people in Babylonia at the time of the earliest records, though they seem originally to have come from the west or north-west. They were probably a Semitic, or partly Semitic, people; whereas the native stock of Sumer (Biblical Shinar), the southern division of Babylonia, spoke an agglutinative tongue, perhaps with Ural-Altaic affinities. There was also a city of Accad. See BABYLONIA; and King's *Sumer and Akkad* (1910).

Acceleration is a term used in the science of Kinematics (q.v.). If a point be moving with variable velocity, its motion is said to be *accelerated*, and the rate of change of velocity is termed its *acceleration*.—For the acceleration of the moon, see MOON.

Accent, in Language, is a special stress of voice laid upon one syllable of a word, by which it is made more prominent than the rest; every word in English has one syllable thus brought markedly into notice. The accented syllable is sometimes indicated by a mark, as *away*, *fortify*. When the accented syllable falls near the end of a long word, there may be one or more secondary accents,

as in *recommen'd*, *subor'dina'tion*. Accent depends upon force of vocal or articulative effort, not upon highness or lowness of pitch. Variations of pitch produce what elocutionists call *inflection*. In English, many nouns are converted into verbs simply by transposing the accent, as *object—object'*. It is accent alone, and not quantity, that determines English measures or metres in versification. No rule can be given as to what syllable of a word shall be accented. There seems to be an increasing tendency in our language to throw the accent towards the beginning of words (see RHYME, METRE, RHYTHM).—*Emphasis* is to sentences what accent is to words; it is a stress laid upon some one word or part of a sentence to make it prominent. If accent is syllabic emphasis, emphasis is logical accent.

Accent, in Music, is analogous with accent in poetry. It is one of the elementary requisites of musical art, that in a series of notes, an emphasis or accent should recur with mostly unbroken regularity. The position of this is generally indicated by bars across the stave, the accent being normally on the first note within the measure. A secondary or weaker accent is sometimes placed on the third beat, whether in common or triple time. More frequently than in poetry, the accent is, for the sake of effect, transferred from its normal place. This is always clearly indicated. What is called by some writers the *rhetorical accent*, is the proper adaptation of the accent in vocal music to that of the words. *Accents*, in liturgical services, are the forms of intonation of various portions in definite musical rhythm.

Acceptance is the signification by the drawee in a bill of his assent to the order of the drawer. It consists in the drawee, or some person duly authorised by him, signing the bill. Words may be added signifying his intention; but these are unnecessary, and may destroy the bill, if, for instance, expressing that other means than money will be used to meet the bill. The acceptance may be before the bill has been signed by the drawer, or when it is overdue, or after having been dishonoured. Acceptance is either general or qualified—i.e. expressly varying the terms of the bill as drawn. A qualified acceptance may be conditional, or partial in amount, or local—i.e. restricting places of payment; or qualified in time; or by one or more drawees, but not by all. The holder of a bill may refuse to take a qualified acceptance. All acceptances are completed by delivery or notification. See BILL of EXCHANGE.

Acceptance is also a term in the law of contract. A contract involves an offer, express or implied, by one party, and an acceptance by the other. It depends on the character of the offer whether an express acceptance is required, or whether a tacit acceptance by acting on the offer is sufficient to complete the contract. The acceptance must meet the offer; otherwise it does not make a contract, but is merely a counter-offer. Acceptance must be within the time fixed by the offer; or, if the offer does not specify any period for acceptance, the acceptance must be within a reasonable time. When the offer is made by letter, the contract is concluded as soon as an acceptance is posted. See CONTRACT.

In the United States the acceptance of an offer concludes a contract, and the rules are similar to those in England. An acceptance of a bill may be *absolute*, when it is a positive engagement to pay the bill according to its tenor; *conditional*, when it is an undertaking to pay the bill on a contingency; *express*, when it is an undertaking, in express and direct terms, to pay the bill; *implied*, when the undertaking to pay the bill is inferred from acts of a character to warrant such

an inference; *partial*, when the undertaking varies from the tenor of the bill; and *qualified*, when the acceptance is either conditional or partial.

Acceptilation (Lat. *acceptilatio*) was a term in Roman law (and adopted in Scots law) for the remission of a debt through an acquittance by the creditor testifying to the receipt of money which never has been paid, or a kind of legal fiction for a free remission. By an obvious transference, the word was used in dogmatic theology for the doctrine laid down by Duns Scotus, and defended by Arminians, that the satisfaction rendered by Christ was not in itself really a true or full equivalent, but was merely accepted by God, through gracious good-will, as sufficient.

Accessary, or **ACCESSORY**. In the criminal law of England, an accessory is a person who is not the chief actor in a felony, nor even present at its perpetration, but who is in some way concerned, either *before* or *after* the fact. An accessory *before* the fact is one who procures or counsels or commands another to commit a crime, he himself being absent. But mere knowledge that a crime is to be committed is not enough to constitute an accessory; there must be active instigation or counsel given. An accessory *after* the fact is a person who, knowing a felony to have been committed, receives, protects, or assists the felon; but merely suffering the principal to escape is not enough. In unpremeditated offences, there can obviously be no accessories *before* the fact; in all crimes under the degree of *felony* there are no accessories at all, but all persons concerned are held to be guilty as principals. There are no accessories in treason, but all are principals, on account of the heinousness of the crime. Accessories must be distinguished from principals in the second degree, who are present aiding and abetting, and generally receive the same punishment as principals.

In the Scottish law, 'art and part' is the equivalent to accessory, but it also includes principals in the second degree. No distinction is made between guilt by commission and guilt by accession; but, except in treason, accession after the crime is not recognised in Scotland. The most common form of it is, however, prosecuted under the name of reset of theft.

In the United States, the common law distinction between principals and accessories has been abolished by statute, and every person concerned in the commission of a crime, whether he directly commits the act constituting the offence, or aids and abets in its commission, is a principal.

Accession. In the law both of England and Scotland, property may be acquired by accession, and this accession may be either natural or artificial. The young of cattle and other animals, for example, belong to the person who is the owner of the mother, and the fruits and produce of the earth to the proprietor of the soil; and for the same reason, the gradual addition to lands on the bank of a river belongs to the proprietor of the land receiving the addition. These are instances of *natural* accession. Property, again, is acquired by *artificial* accession when the original subject of ownership is improved by human industry; thus trees planted, or buildings erected, on the ground of another belong to the owner of the ground itself, and not to the planter or builder.

In the United States, accession is the right to all which one's own property produces; the right to that which is united to it, naturally or artificially, by accretion. If the materials of one person are united by labour to the materials of another, so as to form a single article, the property in the joint product is, in the absence of any agreement, in the

owner of the principal part of the materials by accession. If there be a sale, mortgage, or pledge of a chattel, carried into effect by delivery, and other materials are added afterwards by the labour of the vendor or mortgager, these pass by accession.

Accession, DEED OF. In the practice of Scottish conveyancing, this is a deed by which the creditors of a bankrupt or insolvent debtor approve of a trust executed by the debtor for the general behoof, and consent to the arrangement proposed. It is in the option of a creditor to consent, or refuse consent, to such a deed. The deed is effectual only if all the creditors consent. A non-acceding creditor may at any time apply for sequestration. See **BANKRUPTCY**.

Accidence is the part of Grammar (q.v.) which treats of the inflection of words.

Accident. See **INSURANCE, LIABILITY OF EMPLOYERS, WORKMEN'S COMPENSATION**.

Accidental Colours are the imaginary complementary colours (not caused by light, but due to subjective sensation; see **COLOUR**) which are seen when, after looking fixedly at a bright-coloured object, the eye is turned to a white or light-coloured surface. If the object was red, the accidental colour will be green. Blue corresponds in like manner to yellow.

Accidentals, in Music, are signs of chromatic alteration of the notes, differing from the Signature (q.v.) in applying only to particular notes, and not extending their effect beyond the bar in which they occur, or according to others, the first note of the next bar. They indicate a temporary change of key. They are five in number; the sharp (\sharp), the double sharp (\times), which raise the note to which they are prefixed a semitone and a tone respectively; the flat (\flat) and the double flat ($\flat\flat$), which lower it correspondingly; and the natural (\natural), which annuls the effect of preceding flats or sharps, whether accidental or in the signature.

Accidents, in Logic or Philosophy, are opposed to Essentials, or to Substance. An accident is a property of an object which may be modified, or even be altogether abstracted, in thought or reality, without the object ceasing to be essentially what it is. For the relation of accident to substance, and of attribute to species, see **PREDICABLES, SUBSTANCE**.

Accipitrés, a term applied by Linnæus to Birds of Prey (q.v.), such as the hawk (Accipiter). The order is now called **Falconiformes**, and includes eagles, hawks, vultures, and falcons.

Acclimatisation is that process whereby animals or plants become adapted to, and so thrive in a climate different from that in which they are indigenous. The process, of course, varies widely, according to the amount of difference between the old and the new climate. In cases where the difference is extreme, important changes take place in the constitution, and are often attended with certain diseases described as 'diseases of acclimatisation.' Thus, Europeans settling in tropical parts are liable to disease of the liver; while natives of tropical lands, when resident in England, are exposed to pulmonary disease. The power of bearing changes of climate is greatest in the Anglo-German race, and usually bears a direct ratio to the intellectual development of a race. Some regions have, however, as yet baffled European colonisation. Civilised people display greater ingenuity and strength of will than savages in accommodating themselves to changes of climate, by making careful corresponding changes in their mode of life. Ulloa and Humboldt assert that persons of and above middle age best stand transportation to tropical

climates. Among animals, we find great powers of adaptation to various climates in the horse, dog, cat, and rat; and among plants, in the various cereals, in potatoes, and in several weeds common to almost all climates; but there seems to be a limit to the power, at least as seen in the individual. Acclimatisation beyond a certain point is the work of some generations. Almost all the domestic animals now commonly spread over Europe, and even in high northern latitudes, were originally natives of warm climates. The change produced by the acclimatising of animals may be either an improvement or a deterioration; of the latter, we have an instance in the Shetland pony; of the former, we see an example in the merino sheep of Spain. The reindeer may serve as an instance of the want of the faculty of becoming acclimatised; removed from the cold north to the fertile valleys of a temperate clime, it degenerates and dies. On the other hand, the horse, which is native in the East, arrives at its highest development in England; and the Syrian sheep, brought northward as far as Spain, becomes remarkable for its fine fleece. Spain has a climate much warmer than that of Silesia and Pomerania; and yet the merino sheep bred in these countries have become superior to their ancestors imported from Spain. This is a proof that art may do very much in modifying the influences of climate. Silkworms, brought from China first into Italy, have been acclimatised not only in the south of France, but even on the coast of the Baltic. Recently, attempts have been made to acclimatise in France the llama, the vicuña, and the alpaca of Peru, and with some success in the last instance, as alpacas have been found to thrive pretty well in the Pyrenees.

In America, some interesting experiments in naturalisation have been made. Many European birds have been set at liberty by local societies, and a few species promise to become Americanised. The camel breeds well in a half wild state in Nevada and Arizona; while alpacas, though repeatedly tried, have nowhere thriven. Ostrich-farming was taken up with zeal in Argentina, and soon passed the experimental stage in Arizona and southern California. Australian eucalypts have been successfully introduced on the Roman Campagna; and the Australian wattle (*Acacia*) thrives wonderfully on the previously bare plateaux of the Cape and Natal. The tea-plant grows well in various parts of the United States. The camel does well in Australia, and has been found highly useful in the desert tracts. Several species of trout, salmon, and other fishes have been successfully naturalised in Australasia, notably in Tasmania and New Zealand. America and Australia alike have become the abodes of many noxious weeds from Europe. The English sparrow is a great nuisance in North America; the English rabbit is extremely destructive in Australia and New Zealand. In like manner, the *Anacharis canadensis*, a harmless water-plant in America, has proved an annoying obstruction in many British canals. On the other hand, in the island of Arran and elsewhere interesting and successful experiments in acclimatisation, especially of Australian plants, have been made. In the case of one species, Eucalyptus or gum-tree, the rate of growth has been even greater than in Australia. The introduction of coffee into the West Indies and of cinchona into India offer further examples of successful acclimatisation. It has been very generally believed that plants may become gradually inured to a climate so different from that to which they have been accustomed, that if they had been at once transferred to it they would have perished. On the other hand, it is maintained that each species of plant has certain limits of

temperature within which it will succeed, and that alleged instances of acclimatising have been merely instances of plants formerly supposed to be more delicate than they really were. But as it is certain that different varieties of the same species are often more and less hardy, it would seem that in the production of new varieties by seed, there is still a prospect of the acclimatising, to a certain extent, of species of which the existing varieties are too delicate to grow well in the open air. Of Acclimatisation Societies, the best known is the Paris *Société d'Acclimatation*. The progress which has been made during the past few years in the science of medicine and in sanitation, renders it more probable that attempts made by Europeans to become acclimatised in tropical countries will be successful.

Biologically considered, acclimatisation is part of the general process of modification of organism by environment. When the conditions in the new home are approximately similar, no fresh changes will be imprinted on the organism, and the survival of the imported form is obviously natural. Such cases are instances simply of dispersion, generally by human selection, and hardly of acclimatisation in the strict sense. At the other extreme, the sum of the external forces, or 'natural selection,' may be predominantly adverse, the consequent changes pathological, the result non-survival. The term acclimatisation should thus be restricted to cases between these two extremes, where the plastic organism becomes actively and passively adapted to the new environment. That modifications do take place in consequence of a change of climate and other external conditions, has been recognised from the time of Hippocrates, but how soon these may become really hereditary is still matter of dispute. See CLIMATE, GEOGRAPHICAL DISTRIBUTION, DOMESTICATION, ENVIRONMENT, HEREDITY, PISCICULTURE; Darwin's *Animals and Plants under Domestication*; works on anthropology by Tylor and Waitz; H. Weber's *Climatic Therapeutics*.

Accolade, an essential part of the ceremony by which knighthood was and is conferred. Originally, the grand-master of the order, in receiving the neophyte, embraced him by folding the arms round the neck (*ad collum*). Later, a blow was given with the fist or the flat of a sword (perhaps as the last the knight should suffer to pass unavenged). Now, the sovereign gives the accolade by laying a drawn sword on the shoulders of the kneeling knight-elect, and bids him rise, addressing him with 'Sir' prefixed to his Christian name. See KNIGHTHOOD.

Accommodation, a name given in theological phraseology to a method in Scripture interpretation which explains the form as not necessarily more than the vehicle by which divine and spiritual truth is conveyed to the human understanding. Without such an adaptation, the divine revelation would not be intelligible to man, and thus much of the symbolic method, especially of the Old Testament, is merely a compromise with human weakness. The method of Jesus, in his teaching, is also claimed as an example of accommodation, in his selection of familiar natural phenomena and ordinary human experiences, as the means of conveying to the mind abstract spiritual truths. The secondary fulfilments of prophecy, and the New Testament explanations of the manner in which these were seen in the life of Jesus, are supposed by some to be accommodations.

Accommodation, in Vision. See EYE, VISION.

Accommodation, in Commerce, is either a loan of money directly, or the service rendered when one becomes security for a sum advanced to

another by a third party, as by a banker. For Accommodation Bill, see BILL.

Accompaniment, in Music, is the assisting or aiding of a solo part by other parts, which may consist of a whole orchestra, or a single instrument, or even subservient vocal parts. It is either *ad libitum*, when it may be omitted at pleasure, or *obbligato*, when it forms an integral part of the composition. It serves to support and beautify the solo part, and therefore should not predominate, but merely assist to place the solo part in its brightest light. In this point of view, modern composers have often erred by making the accompaniment too full, and causing it to stand out so independent, that the solo part is often, as it were, entirely lost. This abuse takes place mostly in vocal music; and not only is the effect destroyed, but the vocal organ of the singer is frequently ruined. This is a result, though not a necessary one, of an increasing aim towards a polyphonic style, in which the parts are all of nearly equal value and importance; and it is undoubtedly in this style that the greatest music has been written. The works of Richard Wagner are notable as containing many passages in which the voice is overwhelmed by the orchestral accompaniment, and but few singers have ever been able to cope with this difficulty. The operas of Mozart may probably be regarded as striking the balance most happily on this point. In accompaniment, the composer should keep three principal points in view—harmony, rhythmical figure, and suitable choice of instrumentation, in respect to volume and character of tone; but all must be subservient to the ruling character of the solo part. The accompaniment should, above all things, by its certainty and firmness, prevent wavering. Good accompaniment is as creditable as solo playing; and all qualified orchestras view it as of great importance. In the scores of the older masters, especially Bach and Handel, frequently very faint indications are given of the parts of the accompaniment beyond a *figured bass*—i.e. the bass part with certain recognised figures written above it—indicating the harmony to be played to each note. At that time, the art of playing from this was in general practice among musicians; but it is now necessary to have these parts written out. The work of supplying *additional accompaniments* to these scores, adapted for the modern orchestra, has been performed by numerous eminent musicians, Mozart, Mendelssohn, Franz, and others.

Accoramboni, VITTORIA, a beautiful Roman lady whose story gives the plot to Webster's tragedy, *The White Devil*. She was given in marriage to Peretti, a nephew of Cardinal Peretti, afterwards Sixtus V. (q.v.). After her husband's murder by her brother, she became the wife of the Duke of Bracciano, and was ultimately murdered by a nephew of her last husband at Padua in 1585. See a book by Gnoli (1870).

Accordion, a musical instrument invented in 1829 by Damian, of Vienna. It consists of a small hand-bellows, with a keyboard on one side, containing from five to fifty keys, acting on free metal reeds, so arranged that each sounds two notes, the one in expanding, and the other in contracting, the bellows. Its capabilities are extremely limited. A modified form is called a Melodeon. See CONCERTINA, HARMONIUM.

Account, in Law, means a statement of money transactions showing a balance due by one party to another, or it may show only goods supplied or services rendered by one party, in respect of which money is due to the other. An account is 'open' or 'current' where the balance is not struck or is not accepted by all the parties. In England, where

the parties have agreed to the balance, this is called an 'account stated'. In Scotland a 'fitted account' is entitled to the privileges of a document *in remeratoria*—i.e. it does not require to be signed before witnesses. It is often stipulated, as in the case of a cash-credit, or of a bank and its agent, that an account stated by the official of the bank shall be conclusive, but this affords only a *prima facie* case. Even where accounts have been docketed, errors of calculation can be corrected, and if the settlement has been obtained by misrepresentation or concealment, it may be set aside. There is in Scotland a triennial prescription of tradesmen's accounts (see PRESCRIPTION). In Scotland the Accountant of Court is an important officer who has a general supervision of the statutory accounts lodged in sequestrations, cessios, judicial factories, and testamentary trusts, and also of moneys consigned in court.—For accounts in the wider sense, see BOOK-KEEPING, BANKING, PRESCRIPTION, STOCK-EXCHANGE.—Account Duty, a duty on gifts made by a deceased person within three years of his death has, since the fiscal legislation of 1881–1910, become an important branch of public revenue; see DEATH DUTIES, EXECUTOR.

Accountant is a term given in the United States to any one who keeps accounts, to book-keepers in general; more specially to those who deal with accounts of more than ordinary complexity. In England Accountants and Auditors of Accounts represented as early as the 16th and 17th centuries what was substantially a distinct profession, whose development is recorded in a *History of Accounting and Accountants* by Richard Brown (1905). Most public companies, such as banks and railway companies, have an officer called an accountant, whose duty it is to take charge of the books and accounts of the concern, and to make up periodical statements and balance-sheets. It is only in recent years that the profession of an accountant has come to be recognised as a special branch of business, its functions having been usually performed, as they still sometimes are, by lawyers and agents. The business of an accountant cannot well be very strictly defined, but it may be stated generally as falling under two divisions: (1) the management or realisation of estates, whether of bankrupts or others; and (2) all matters involving the investigation of business books, as auditing the books of private firms or public companies, and making up balance-sheets, statements of all kinds, and reports. There are several societies of accountants incorporated by royal charter, and a member or fellow of one of these is termed a chartered accountant (C.A. or F.C.A.). The principal society in England is 'The Institute of Chartered Accountants in England and Wales,' incorporated in 1880; and in Scotland there are chartered institutes in Edinburgh (1854), Glasgow (1855), and Aberdeen (1867).

Accra, capital of the Gold Coast Colony, and most important town on the coast, lies slightly to the W. of the long, of Greenwich. It is a healthy place, much attention being paid to the drainage and water-supply, and has considerable export trade in palm-oil, ivory, gold, india-rubber, cocoa, &c. The town has telegraphic communication with England, the Niger, and the French and Portuguese settlements to the south, and a wireless station. Pop about 20,000.

Accrington, a manufacturing town of Lancashire, a municipal (1878) and parliamentary (1918) borough. It lies in a deep valley, surrounded by hills, 22 miles N. of Manchester, and 5½ miles E. of Blackburn. The oldest church dates from 1554, and was rebuilt in 1763. The town-hall (1857) is a handsome building, and there is a neat market-hall.

It is a great centre of calico-printing, cotton-spinning, the making of cotton machinery; other industries are dyeing, chemical-works, and iron-founding, with coal-mining in the neighbourhood. Pop. (1841) 8719; (1901) 43,095; (1911) 45,029; (1921) 43,610.

Accum. FRIEDRICH, born in Westphalia in 1769, came to London in 1803. He is known in this country chiefly on account of his *Practical Treatise on Gas-light*, and other chemical works. He greatly promoted the introduction of gas-lighting. In 1822 he became a professor in a technical institute in Berlin, where he died in 1838.

Accumulation is a legal term applied to the putting by of interest, or rents, and converting them into capital by investment, of which the income is again capitalised. Restrictions upon accumulation are enforced by the rules against Perpetuities (q.v.) and by the Accumulations Acts of 1799 (see THELLUSSON ACT) and 1892. By the Thellusson Act it is forbidden to accumulate income for a longer period than the life of the trustee or settlor, and twenty-one years thereafter. This act applies to movable estate in England and Scotland, and by the Rutherford Act, 1848, the prohibition was extended to the rents of land in Scotland. If the direction is given to accumulate for a longer period, the settlement is not void, but is given effect to so far as permitted by law. Accumulation is also applied in Scotland to the charging of compound interest. Such accumulation is permitted on bankers' accounts overdrawn, in certain cases of fixed commercial usage, or where there has been an abuse in a party trusted with funds and violating his trust. See INTEREST.

Accumulator. In such pieces of hydraulic apparatus as hydraulic cranes or hoists, unless the height of the available column of water, or head-pressure, as it is called, is considerable, the necessary amount and constancy of pressure is obtained by means of an accumulator. This usually consists of a dead weight acting by means of a plunger on the water column. Sometimes, however, steam is used to put on the required pressure, in which case the arrangement is called a steam accumulator.—In Electricity, the accumulator is an arrangement by which electrical energy can be stored for a considerable time in some potential form, so as to be used at will for the production of electric currents. See ELECTRICITY.

Acel'dama (Chaldee, 'field of blood'), the name given to the potter's field bought by the priests, as a burial-place for strangers, with the money which Judas had received for betraying Jesus, and which, in the horror of his repentance, he flung at their feet before hanging himself.

Aceph'ala (Gr., 'headless'), a term used from the time of Aristotle in reference to the class of bivalve molluscs or Lamellibranchs (see BIVALVES), has in the main retained its application, though some forms which it once included, such as the sea squirts in Cuvier's classification, have been removed to other divisions.

Acer and Aceraceæ. See MAPLE.

Acerria, an ancient city of Southern Italy, 9 miles NE. of Naples by rail. It has a cathedral (rebuilt after the earthquake of 1788), a sulphurous mineral well, and 18,000 inhabitants.

Acetanilide. See ANTIFEBRIN.

Acetic Acid, CH₃·COOH, the sour principle in vinegar, is the most common of the vegetable acids. It occurs in nature in the essences of some plants, and is formed as a decomposition product of organic matter. It is prepared on the commercial scale by the destructive distillation of wood. A brown distillate—pyroligneous acid—is obtained, containing methyl alcohol, acetic acid,

acetone, and some impurities. After several chemical processes, commercial acetic acid is obtained from it. Glacial acetic acid is the pure acid, and is got by the distillation of anhydrous sodium acetate with sulphuric acid. It is a colourless crystalline solid, melts at 16.5° C., boils at 118° C., and has a pungent smell. Acetic acid is readily obtained by the oxidation of alcohol, by exposing a large surface of dilute alcohol to the air. Fermentation soon sets in, due to a minute ferment—*Mycoderma aceti*—which is present in the atmosphere. This ferment gets into the solution, grows and multiplies, and by its presence causes oxidation of the alcohol to acid. The ferment acts as a catalyser. The dilute acetic acid formed is Vinegar (q.v.). The change is accompanied by the absorption of oxygen, one atom of which combines with two of hydrogen to form water, aldehyde being left. Further oxidation then takes place, acetic acid being formed thus:

From the mode in which acetic acid combines with bases to form salts, it is evident that one atom of the hydrogen differs from the other atoms in being replaceable by a metal or an alkyl radical (as ethyl, C₂H₅), and on this account acetic acid is called a monatomic acid, and its formula is usually represented as HC₂H₃O₂; that of acetate of potash being KC₂H₃O₂, and of acetate of ethyl, C₂H₅C₂H₃O₂. A striking experiment may be made illustrating the mode in which alcohol is converted into acetic acid. If slightly diluted alcohol be dropped upon platinum-black, the oxygen condensed in that substance acts with great energy on the spirit, and acetic acid is evolved in vapour. Here the whole office of the platinum is to determine the oxygen of the air and the hydrogen of the alcohol to unite. In the commercial processes for manufacturing vinegar, a ferment or enzyme takes the place of the platinum-black, and determines the same change. The anhydride of acetic acid (see ANHYDRIDES) is formed by the action of chloride of acetyl on acetate of potassium. It has the composition (C₂H₃O)₂O, and unites with water to form acetic acid. The salts of acetic acid, called ACETATES, are numerous and important in the arts. Calcium acetate is used in the preparation of acetone. Lead acetate or sugar of lead is important (see LEAD). Iron and aluminium acetates are used as mordants for dyeing, on account of their property of being precipitated as insoluble salts by heat. Acetic acid is used chiefly for the preparation of acetates and organic dyes, and also to a slight extent in medicine.

Acetone, CH₃·CO·CH₃, or dimethyl ketone, is the lowest member of the ketones, commercially prepared by the distillation of calcium acetate. It may also be obtained from the destructive distillation of wood, being separated from wood spirit by distilling over calcium chloride. It is a limpid liquid, having a taste like that of peppermint, and is readily soluble in alcohol, ether, and water. Its specific gravity is about .79, its boiling-point being 56° C. It is largely used for the manufacture of chloroform, which is obtained from it by distillation with bleaching-powder; also in making iodoform and cordite. It is a solvent for gums and resins.

KETONES are a group which have all the same characteristic grouping, namely, a carboxyl (CO) united to two carbon atoms—e.g. C₆H₅·CO·C₆H₅. They are the aldehydes of secondary alcohols (see ALCOHOL). Acetone is typical, and is obtained by

the oxidation of secondary propyl alcohol, two atoms of hydrogen being removed.

Secondary Propyl Alcohol. Acetone.

Acetyl, or **ACYL**, is an organic radical supposed to exist in acetic acid and its derivatives; the rational formula for acetic acid being on this hypothesis $(\text{CH}_3\cdot\text{CO})\text{OH}$.

Acetylene, a powerful illuminant, first made on a commercial scale in 1895, is a colourless, heavy gas, with an unpleasant odour. It has the formula C_2H_2 , and is the lowest compound of carbon and hydrogen. The exceptional brilliancy of the flame is due to the high percentage of carbon, and on this account burners with very fine holes must be used to avoid sooting up. It can be obtained in a fairly pure state by heating ethylene dibromide with alcoholic caustic potash:

It is interesting chemically, as it can be prepared synthetically by the union of its elements, hydrogen being passed through an electric arc between carbon electrodes. On the commercial scale it is obtained from carbide of calcium. The action of water on carbide forms acetylene and lime:

Acetylene is in general use as an illuminant for country houses, motor-cars, bicycles, &c., for the reason that the generating plant is compact and simple. Generators are all of similar construction. The carbide is contained in one compartment and water in another. The water drips slowly on to the carbide, the flow being regulated by the amount of gas consumed. The gas passes away through a purifier, and thence to the burner. The waste lime collects at the bottom, and must be removed before recharging with carbide. Acetylene when mixed with air is explosive. With copper it forms an acetylide, which is violently explosive in a dry state. Care must therefore be exercised that no copper apparatus is used in an installation. See CALCIUM, GAS (HEATING, &c.).

Achaia, a small Greek district lying along the northern coast of the Peloponnesus, forms with Elis a department (pop. 272,000) in the modern kingdom. Its chief town is Patras (q.v.).—The Aryan Achæans were not the earliest inhabitants of Greece, but seem to have invaded from the north a Mediterranean race characterised by the Mycæan culture revealed by Schliemann, connected with the Minoan culture of Crete (see GREECE). As the Achæans (Achæans) were the ruling people of the Peloponnesus in heroic times, Homer speaks of the Greeks generally as *Achaioi*. Their twelve little towns formed a confederacy, renewed in 281 B.C., and subsequently extended, under the name of the *Achaean League*, throughout Greece, until 146 B.C., when Greek liberty fell under the power of Rome.

Achard, FRANZ KARL, born in 1754 at Berlin, distinguished himself by his improvements in the manufacture of beetroot sugar; the king of Prussia having given him a farm whereon to found a model factory. Achard was called to Berlin as director of the physical class in the Academy of Sciences, and died in 1821.

Acha'ës, the constant companion of Æneas in his wanderings after the capture of Troy. He is always styled by Virgil 'fidus Achates,' hence the name has become a synonym for a trusty defendant and companion.

Acheen. See ATCHIN.

Achelous, now called *Aspropotamo*, a river in western Greece, rises in Mount Pindus, flows south and south-west, dividing in its lower course Ætolia from Acarnania, and falls into the Ionian

Sea opposite Cephalonia. The alluvial deposits at its mouth are very extensive. In Greek mythology, the god of this river was the oldest of the river gods, and was the son of Oceanus and Tethys.

Achene, a dry, indehiscent, single-seeded fruit. The term is often restricted to fruits like those of the common dock, resulting from a superior ovary, the wall of which does not adhere to the seed. But it is perhaps better to extend the term achene to all dry, indehiscent fruits, including forms like grains of wheat, 'seeds' of dandelions, nuts of hazel, and so on. See FRUIT.

Ach'eron, the name given to several rivers by the ancients, always with reference to some peculiarity, such as black or bitter waters, or mephitic gases. The Acheron, in Thesprotia in Epirus, flowing through the lake Acherusia into the Ionian Sea; another river of the same name in Elis, now called Sacuto; and several streams in Egypt—were all supposed to have some communication with the infernal world. According to Pausanias, Homer borrowed from the river in Thesprotia the name of his infernal Acheron, which the later poets surrounded with many imaginary horrors. Other lakes or swamps of the same name occur near Hermione in Argolis, between Cumæ and Cape Misenum in Campania, and in Egypt, near Memphis.

A-cheval Position. When troops are arranged so that a river or highway passes through the centre and forms a perpendicular to the front, they are said to be drawn up in *a-cheval* position.

Achievement, in Heraldry, originally arms granted for the performance of an honourable action; hence a complete representation of one's armorial ensigns. See HATCHMENT.

Achill, or 'Eagle' Isle, off the west coast of Ireland, is reckoned within the county of Mayo. It is 15 miles long by 12 miles broad, and has a very irregular coast-line. It has a wild and desolate appearance; most of the surface is boggy; of the 51,500 acres which the island contains, not 500 are cultivated. There are three villages in Achill, and a number of hovels or huts scattered over its barren moors, sometimes in small clusters, forming hamlets, but so wretched as hardly to be fit for beasts. Achill rises towards the north and west coast, where the mountains attain an elevation of 2000 feet. One of them, Achill Head, composed, like the rest of the island, wholly of mica-slate, presents towards the sea a sheer precipice from its peak to its base, a height of 2192 feet. There is a mission-station in the island. The population—4000 in 1851—exceeded 6200 in 1891, and is now about 5300.

Achillæa. See MILFOIL.

Achilles, the hero of Homer's *Iliad*, was the son of the nereid Thetis and Peleus, who was son of Æacus, and king of the Myrmidons at Phthia in Thessaly. He was taught eloquence and the arts of war by Phoenix, and the healing art by the centaur Chiron. He led his Myrmidons in fifty ships to Troy, although he knew that he would not return. In the war he was the bulwark of the Greeks, being at once the swiftest and bravest hero in the army. He destroyed many towns in the Troad before his quarrel with Agamemnon, with which the *Iliad* opens. A pestilence in the Greek camp being ascribed to the anger of Apollo, whose priest had been robbed of his daughter Chryseis by Agamemnon, that chief was compelled by the army to send the girl back to her father. On this he carried away Briseis, the fair captive of Achilles. The latter now retired to his tent, and neither the splendid offers made by Agamemnon nor the disasters of the Greeks could afterwards move him to take any

part in the contest, until his dear friend Patroclus was slain by Hector. The hero then buckled on his armour, which had been made for him by Hephaestus, and of which the shield is described at great length by Homer. The fortunes of the field were now suddenly changed in favour of the Greeks; and the vengeance of Achilles was not satiated until he had slain a great number of the Trojan heroes, and lastly Hector himself, whose body he fastened to his chariot and dragged into the Grecian camp. He then buried his friend Patroclus with great funeral honours. King Priam, the father of Hector, came by night to the conqueror's tent, and prayed that the body of his son might be given to him. Achilles consented; and with the burial of Hector the *Iliad* closes. The hero himself fell in battle at the Scæan gate before the city was taken. His death is not expressly mentioned in the *Iliad*, but in the *Odyssey* his remains are buried, together with those of Patroclus, in a golden urn on the coast of Hellespont, where a mound was raised over them. Such is the Homeric account of Achilles, the swift-footed, fair-haired hero of the *Iliad*. He is at once the handsomest and bravest of the Greeks, terrible to his foes, tender and gentle with his friends, magnanimous and proud, defiant to the unjust prince, but reverent and obedient to the gods. He loves music, is the most devoted of friends, has a passionate hunger for glory, and dies in the full splendour of his youth. There are many later traditions which fill up the bare outlines of his history. His mother dipped him when an infant into the Styx, and hence he became invulnerable except in the heel by which she held him. To escape the fatal expedition to Troy, she hid him in the disguise of a girl at the court of Lycomedes at Scyros, but here his sex soon made itself known, for one of the king's daughters became by him the mother of a son, Pyrrhus or Neoptolemus. Ulysses discovered him by an artful stratagem. Disguised as a pedlar, he came to offer his wares for sale: the girls at once showed a natural interest in the articles of dress and ornaments, but the eager interest which he could not hide in the weapons of war at once revealed the youthful hero. Among his achievements at Troy are his conquest of the Amazon Penthesilea and of Memnon. Nor does he fall by human hands alone. Some say that he was killed by Apollo himself; others, that the god merely guided the weapon of Paris. Another story tells how the hero fell in love with Polyxena, daughter of Priam, and how he came unarmed to meet her in a temple of Apollo, where he was shot in the vulnerable heel by the treacherous Paris. His body was rescued by Ulysses and the Telamonian Ajax, and these heroes had a fierce contest for his famous armour. The hero was carried to the islands of the blessed, where he was united to Medea or Iphigenia.

Achilles Tattius, or **STATIUS**, an Alexandrian Greek rhetorician, author of the romance of *Leucippe and Cleitophon*, proved by an Oxyrhynchus papyrus fragment to be not later than the first half of the 4th century A.D., is said to have become a Christian bishop, and may have been an astronomer.

Achilles Tendon (*Tendo Achillis*) attaches the soleus and gastrocnemius muscles of the calf of the leg to the heel-bone. It is capable of resisting a tension strain equal to 1000 lb. weight; and yet it is occasionally ruptured by the contraction of these muscles in sudden extension of the foot, such as may occur in the case of old gentlemen dancing, or in the attempt to recover equilibrium after a stumble. For the name, see **ACHILLES**. Ancient surgeons regarded wounds or serious bruises of the Achilles tendon as fatal.

Achimenes, a genus of plants of the natural order *Gesneraceæ*, cultivated in stoves and green-houses for the beauty of their flowers. The species are numerous—natives of tropical America.

Achlamydeous. See **APETALOUS**.

Achromatism, the property in virtue of which certain combinations of lenses, &c., refract a beam of light without producing coloured fringes. Any arrangement of lenses or prisms which refract light without dispersion (see under **LIGHT**) is achromatic.

Hall in 1733, and later Dollond (independently), found that certain media give large refraction with small dispersion, while others give small refraction with large dispersion; so that the dispersion produced by one medium can be made to annul that due to another, while its refraction is not entirely annulled. For example, by properly combining a convex lens of crown-glass with a concave one of flint-glass, a compound achromatic lens can be produced. The achromatism in the above arrangement, and in every other arrangement yet tried, is not absolutely perfect. The reason is that such media do not give exactly similar spectra (see **SPECTRUM**)—i.e. the ratio of the angular separations of any two pairs of rays is not quite the same for the different media. A combination of three lenses, or prisms, gives a better approximation to absolute achromatism than a combination of two. Blair in 1791 constructed an achromatic telescope giving very fine definition for high magnifying power. He used a compound lens consisting of two glass lenses enclosing a liquid. Modern glasses can be made of such quality as to give practically perfect achromatic combinations.

Acidimetry is the determination of the percentage of real acid contained in a sample of a hydrated acid, as sulphuric or nitric acid. In most cases, if we know that no foreign body is present, it is possible to determine the percentage by means of the specific gravity, as indicated by the Hydrometer (q.v.). Usually, however, other substances, which alter the specific gravity, may be present, and recourse is then had to one of the following methods:

(1) By volumetric analysis, in the manner described under **Alkalimetry** (q.v.).

(2) By the gravimetric process. This may be conducted in two ways, which will be best understood by an example of each. Sulphuric acid forms several insoluble salts, the sulphate of barium refusing to dissolve, not only in ordinary fluids, but even in strong acids. When chloride of barium is added to a liquid containing sulphuric acid, the sulphate of barium is precipitated, and after due precautions have been taken to insure its purity and to avoid erroneous conclusions, it may be weighed and the amount of sulphuric acid calculated therefrom.

A more rapid method consists in adding to the sample some carbonate of soda, and noting the amount of carbonic acid disengaged. This is readily accomplished by performing the operation in a weighed flask, and determining the loss of weight after the carbonic acid gas has been liberated. Of course many precautions are essential. See also **ANALYSIS**.

Acids. An acid is a chemical compound distinguished by the property of combining with bases (oxides and hydroxides) in definite proportions to form Salts (q.v.). The most striking characteristics of acids are a sour taste and the property of reddening blue litmus-paper. They are also mostly oxidised bodies; and at one time oxygen was thought to be essential to an acid, as the name *oxygen* (the acid-producer) indicates. Subsequent experience has extended the definition. The ele-

ments that form the strongest acids with oxygen are the non-metallic, and most of them have more than one stage of acid oxidation. Thus sulphur unites with oxygen to form two oxides, SO_2 and SO_3 , which, in combination with water, yield respectively sulphurous and sulphuric acid. Similarly, arsenic forms two oxides, As_2O_3 and As_2O_5 , corresponding to arsenious and arsenic acids. The higher stage of oxidation forms the stronger and more stable acid. Except arsenic, all metals that form acids with oxygen have also, at a lower stage of oxidation, one or more oxides. To these inorganic acids containing oxygen must be added the organic acids, composed of carbon, hydrogen, and oxygen. Belonging to this extensive group are oxalic acid, $\text{H}_2\text{C}_2\text{O}_4$; acetic acid, $\text{HC}_2\text{H}_3\text{O}_2$; and formic acid, HCHO_2 . There are also acids found in animal fluids, or resulting from their decomposition, which contain nitrogen in addition to the three elements above named; such is uric acid, $\text{H}_2\text{C}_4\text{H}_2\text{N}_4\text{O}_6$. The *hydrogen acids* are formed of hydrogen and a radical, either simple or compound. The most important of these, and the type of its class, is hydrochloric, HCl ; others are sulphuric (H_2SO_4) and hydrocyanic (HCN) acids.

The Ionisation Theory explains many of the properties of acids. Every acid in dilute solution gives numerous ions by ionisation—i.e. dissociation. Two sets of ions are formed, positive ions (hydrogen ions, in the case of acids) and negative ions. The latter may be a compound radical like sulphate, SO_4' , or an element like chloride, Cl' . An acid which is ionised is represented thus :

The acidic properties of an acid are wholly due to the positive hydrogen ion. The relative 'strength' (or activity) of two acids is dependent on the amount of ionisation—i.e. dependent on the number of hydrogen ions. In solutions of acetic acid, and hydrochloric acid of equal concentration, the former is not nearly so 'strong' an acid as the latter, because it is not so much ionised. Acetic and oxalic acids are 'weak' acids; sulphuric, nitric, and hydrochloric acids are 'strong' acids.

Acids have one or more atoms of hydrogen which are replaceable by a metal, when the latter is represented in the form of a hydroxide. Thus nitric acid and sodium hydroxide yield nitrate of soda and water :

in which reaction the hydrogen of the nitric acid is replaced by the sodium of the sodium hydroxide (caustic soda), and as only one atom of hydrogen is replaced, nitric acid is said to be *monobasic*. When an acid admits of the displacement of two atoms of hydrogen, it is termed *dibasic*—as tartaric, oxalic, and sulphuric acids; and when three atoms can be replaced—as in common phosphoric acid, H_3PO_4 , in which H_3 may be replaced by K_3 or Ag_3 , the acid is termed *tribasic*. The more important acids are included in the following list :

Acids containing no oxygen: Hydrochloric, HCl ; hydrobromic, HBr ; hydriodic, HI ; hydrocyanic, HCN ; hydrosulphuric or sulphuretted hydrogen, H_2S .

Inorganic acids containing oxygen: Boracic, H_3BO_3 ; carbonic, H_2CO_3 ; chromic, H_2CrO_4 ; hypophosphorous, $\text{H}_3\text{P}_2\text{O}_3$; nitric, HNO_3 ; phosphoric, H_3PO_4 ; phosphorous, H_2PHO_3 ; sulphuric, H_2SO_4 ; sulphurous, H_2SO_3 .

Organic acids: Acetic, $\text{HC}_2\text{H}_3\text{O}_2$; benzoic, $\text{HC}_7\text{H}_5\text{O}_2$; citric, $\text{H}_3\text{C}_6\text{H}_7\text{O}_7$; gallic, $\text{H}_4\text{C}_7\text{H}_5\text{O}_3$;

lactic, $\text{HC}_3\text{H}_5\text{O}_3$; salicylic, $\text{HC}_7\text{H}_5\text{O}_3$; tartaric, $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$. See the articles on the several acids.

The most characteristic inorganic acids (hydrochloric, nitric, phosphoric, sulphuric) are used in medicine in a very dilute condition as tonics and astringents, and to allay thirst in fevers. They corrode the teeth, however, and if long administered tend to disorder digestion; so they must be used with caution. Most of the group have special, some (as hydrocyanic, oxalic) extremely poisonous actions. The stronger acids, when concentrated, are powerful caustics.

Applied to rocks, acid, as opposed to basic, means rich in silica.

Acipenser. See STURGEON.

Acì-realè, a town of Sicily, in the province of Catania, 50 miles SW. of Messina by rail. It lies on a bed of lava at the foot of Mount Etna, where the small river Aci (*Acis*) enters the sea. It is the see of a bishop, and has famous mineral wells and sea-bathing; and near it are spots associated with the myths of Acis and Galatea, and Polyphemus. The 36,000 inhabitants depend largely on agriculture, and on manufactures of pottery and leather.

Acis, in Ovid's account, a son of Faunus, beloved by the nymph Galatea, and through jealousy killed by Polyphemus the Cyclops. He was crushed under a huge rock, and his blood, as it gushed from beneath the rock, was changed by the nymph into the river Acis.

Ackermann, RUDOLPH, a native of Saxony (born 1764—died 1834), came in 1795 to London, where he opened a print-shop in the Strand. He introduced lithography as a fine art into England, and was the originator of the 'Annuals' (q.v.), which he commenced by his *Forget-me-not*, published in 1823 and following years. Among the illustrated works published by him were his *Repository of Arts, Literature, and Fashions* (1809-28), and works illustrating London, Westminster Abbey, Oxford, and Cambridge. He greatly promoted engraving in England.

Ackworth. See PONTEFRACI.

Acland, SIR HENRY WENTWORTH, K.C.B. (1834), regius professor of medicine at Oxford 1858-94, was born 23d August 1815, from Harrow proceeded to Christ Church, Oxford, and having in 1841 obtained an All Souls fellowship, in 1848 took his M.D. In 1890 he was made a baronet. He died 16th Oct. 1900.—His eldest brother, Sir THOMAS DYKE ACLAND, born at Killerton, Devon, 25th May 1809, was educated at Harrow and Christ Church, entered parliament in 1837 a Conservative, but in 1865 turned Liberal. In 1871 he succeeded his father as eleventh baronet. He died 29th May 1899. His second son, SIR ARTHUR HERBERT DYKE ACLAND, born in 1847, was educated at Rugby and Christ Church, and in 1885-99 was Liberal M.P. for the Rotherham division of Yorkshire, in 1892-95 was Vice-president of the Council (Education).

Acclinic Line is a name for the magnetic equator, which cuts the terrestrial equator, inasmuch as on that line the magnetic needle has no dip, but lies horizontal. The acclinic line is irregular and also variable. *Acclinic* is from the Greek words signifying 'not bending.' See MAGNETISM, DIPPING-NEEDLE.

Acne is an important skin disease. It is associated with dyspepsia, constipation, and other functional irregularities, and insufficient exercise is often a cause. Any local irritation is apt to bring out a crop of the pimples in predisposed people. The sebaceous follicles of the Skin (q.v.) are the primary seat of the affection. Their natural secretion accumulates in their interior, and there is at the same time a tendency to inflammation of the

follicle and surrounding tissue. It is by no means rare to find on the face and shoulders of young persons about or above the age of puberty a number of black spots, each of which is placed on a slightly-raised pale base. These black points are called *comedones*. Pressure at the base occasions the expulsion of a little, elongated, spiral, white mass, with a black point or anterior end, commonly but erroneously regarded as a worm; though in the midst of the white mass of sebaceous matter, a parasite, *Acarus folliculorum* (q.v.) is occasionally found. Interspersed are other spots, with the base more raised and inflamed, which become more or less perfect pustules, each of which rests on a comparatively large red base. Around some of the inflamed follicles, coagulated lymph (to use the old phraseology) is thrown out, and a small hardened mass is the result. According as one or other of these appearances preponderates, we have different varieties of this disease. When the pustule is the most striking feature, the affection is called *Acne simplex* or *vulgaris*; when the black points abound, it is *Acne punctata*; and when there is decided induration, it is *Acne indurata*. We have already mentioned the age at which this affection commonly occurs: it is never seen in children, and is rare in aged persons.

As long as there is no inflammation, the treatment simply aims at favouring the escape of the contents of the sebaceous follicles, by rubbing the face and other affected parts with cold cream at bedtime, washing on the next morning with soap and water, and vigorous friction with a towel or gentle pressure with a 'comedo extractor.' When acute inflammation is present, and the pustules are very tender, dabbing with eau de Cologne or with weak solution of mercuric chloride in spirit gives relief; and subsequently sulphur ointment is useful. *Acne indurata*, which is the least tractable of the three forms, is often benefited by repeated painting with tincture of iodine; and vaccines made from the bacteria in the pustules form a favourite method of treatment. In all these cases the state of the digestive and sexual organs must be carefully attended to.

ACNE ROSACEA, also called *Rosacea* and *Gutta Rosea*, is so different from the forms of acne above described that it is regarded by most authorities as a distinct disease. It usually first appears at or near the end of the nose; and in some cases it is confined to the nose, while in others it extends to the cheeks, forehead, chin, or even to the whole face. The skin in the part affected assumes a deep red colour, usually transient at first, but returning either on no special provocation, or in consequence, apparently, of some gastric or other disturbance, and after a time becomes permanent; pimples resembling those of *Acne simplex* may appear, but are associated with itching and burning sensations not present in the ordinary forms of acne. The skin of the diseased part, in some cases, is irregularly swollen, and may become enormously hypertrophied, especially that of the nose. In such cases, it is marked with blue or red streaks, caused by congestion and enlargement of the capillaries; the whole surface, in a severe case, presenting a very disagreeable and repulsive appearance. This affection is no doubt often a result of intemperate living, but it may occur in persons of regular habits of life. Disorder of the digestive system is so often associated with it, as to exclude the idea that the combination is accidental, and the skin disease may often with great probability be referred to gastric disturbance as the exciting cause. In women, however, it is very frequently associated rather with disorder of the menstrual functions. The disease is confined almost exclusively to persons in middle or advanced life, and women are especially liable to it about the period in which what is popularly known as the

'change of life' occurs: moreover, it has occasionally been observed to be hereditary.

The general treatment must be governed by the digestive or menstrual disorders associated with it; and a nourishing but bland and non-stimulating diet—above all, abstinence from alcohol—is of great importance. In the early stages, and in irritable forms of the disease, the local treatment should be soothing. Emollient lotions, such as thin starch, a bismuth and calamine lotion, &c., may be occasionally used during the day, and in severe cases a bread poultice may be applied to the face at night. When the affection becomes indolent, the emollients should be gradually replaced by stimulating applications, which have also the effect of constricting the dilated blood-vessels. For this purpose a lotion containing precipitated sulphur, calamine, and glycerine is useful, or a 10 per cent. solution of ichthyol in water. When the veins are greatly dilated they must be destroyed by incisions or touched with the galvanocautery; if the skin be much hypertrophied, removal of pieces by a surgical operation often produces great improvement in appearance.

Acometæ (Gr. *akomētai*, 'sleepless ones'), a congregation of monks founded in 460 near Constantinople, whose peculiarity it was, by means of alternating choirs, to keep divine service going on day and night without intermission in their monastery. They ceased to exist in the 6th century.

Acokanthera, an African genus of apocynaceous plants, which furnishes Zulu arrow-poison.

Acolytes (Gr., 'followers') were the young clerics who assisted the bishops and priests in the performance of religious rites, lighting the candles, presenting the wine and water at the communion, and the like offices. They were considered as in holy orders, and ranked next to sub-deacons. These services have, since the 7th century, been performed by laymen and boys, who are improperly called acolytes; but in the Catholic Church, aspirants to the priesthood are still at one stage consecrated as acolytes. See **ORDERS (HOLY)**.

Aconcagua, the highest peak of the Andes and of the American continent, rising to a height of 23,000 feet. The mountain, which is an extinct volcano, is about 100 miles ENE. of Valparaiso, near the Chilean frontier, but within the Argentine boundary. It gives name to a Chilean province. (Pop. 117,000).

Aconite (*Aconitum*), a genus of Ranunculaceæ (q.v.), having five petaloid sepals, of which the

Monk's-hood (*Aconitum napellus*):
a, fruit; b, root.

upper one is helmet-shaped; and two hammer-headed petals (nectaries) concealed within the

helmet-shaped sepal. The fruit consists of 3-5 follicles. *A. napellus*, the common Wolf's-bane or Monk's-hood, often cultivated in flower-gardens for the sake of its erect racemes of blue flowers, is a doubtful native of England, but common in some parts of Europe. The roots are fusiform and clustered. The root and whole plant are very poisonous, as containing the alkaloid aconitin. Some sixty species of aconite are known, natives of north temperate mountainous regions both of the eastern and the western hemispheres. The virulent *bikh* poison of India, equally fatal in its effects whether introduced into wounds or taken into the stomach, is prepared from the roots of several species, including *A. ferox*, *A. album*, or white-flowered monk's-hood, a native of the Levant, and *A. lycoctonum*, yellow-flowered monk's-hood, or wolf's-bane, a native of the Alps, are not infrequent in our flower-gardens.—The so-called Winter Aconite, a genus of dwarf spring-flowering ranunculaceæ, is technically called *Eranthis*, and has half-a-dozen species, including *E. hiemalis* and *E. sibiricus*. *E. hiemalis* is naturalised in Britain. The petals take the form of honey-bearing tubes. The sepals are light yellow.

ACONITIN, the active principle of monk's-hood and other aconites, is one of the most potent poisons known, so small a quantity as $\frac{1}{100}$ th of a grain of the pure alkaloid having nearly proved fatal. Hence its recognition in poisoning cases is a matter of difficulty, and requires delicate tests. When applied to the eye in even very dilute solution, it causes a sensation of intolerable heat and tingling, the pupil at the same time contracting. This tingling, associated with numbness, is felt when a piece of aconite root is chewed, and on account of this peculiar property, aconitin, or a preparation of aconite, is sometimes used in the treatment of neuralgia, rheumatism, and toothache.

Acorn. See OAK.

Acorn-shells (*Balanus*), a genus of Cirripedes (q.v.), in the class Crustacea. The classical title refers to that remote resemblance to acorns which their popular name also records. They occur in great abundance incrusting the rocks between high and low water mark, and are exceedingly familiar objects. At first sight, and in their adult form, all cirripeds are so unlike crustaceans, that even Cuvier regarded them as molluscs. In 1829, however, their true nature was detected by Vaughan Thompson, who observed the young forms to be free-swimming, and to exhibit characters which stamp them at once as crustaceans.

Structure.—The common sessile acorn-shell may be briefly described in Huxley's words as 'a crustacean fixed by its head, and kicking its food into its mouth with its legs.' The body is enveloped in a fold of skin, or mantle, which forms round about the animal a conical protective shell of six pieces, and a fourfold movable lid. When the animal is active (only, of course, under water), six pairs of curl-like double legs may be seen alternately protruded and retracted through the valvular opening of the shell. These are borne on the thorax of the animal, and serve to brush the floating food down to the mouth, where it is seized and masticated by the three pairs of jaws. The abdominal portion of the animal is degenerate, and the characteristic crustacean jointing is at best indistinct. Since the animal really stands on its head, the single pair of antennæ are found on the middle of the base or lower surface, and are extremely reduced. The attachment is effected by the hardened secretion of complex cement-glands, which probably represent modified excreting organs. The special sense organs degenerate, but the nervous system is well developed, and the surface of the legs

seems to have a general tasting sensitiveness. The alimentary canal is in no way peculiar; and though no heart has been demonstrated, the blood has a definite course. Respiration must be largely effected by the ceaselessly waving legs, but there are also folded plates on the inside of the mantle which may represent special breathing organs. The acorn-shells are hermaphrodite, and the eggs are attached to the folded plates just mentioned. When the young larvæ free themselves from their egg-cases the shell is opened, and the legs cease to kick till they effect their escape.

Life-history.—The contrast between the sessile adults and the free-swimming young is very striking. The first larval stage is a *Nauplius* (q.v.) like that of other lower crustaceans. It has the usual three pairs of legs, an unpaired eye, and a delicate shield on its back. It moults several times, grows bigger, and develops a firmer shield, a longer spined tail, and stronger limbs. The second short chapter in its history is known as the Cypris stage, in which the larva acquires two side eyes, six pairs of swimming legs, a bivalve shell, and other organs. At the end of this stage, during which no food is

a, Pelagic larva of acorn-shell; b, external shell of adult; c, vertical section of adult. (From Darwin's Monograph.)

eaten, the larva becomes fixed by its feelers and the glue of the cement-gland. A new regime begins; some organs such as the side eyes, the antennæ, the bivalve shell, the tail, and the swimming legs, are lost; while new structures appear, such as the curled waving legs, and the incipient external shell. During these changes there is quiescence and fasting, and the stage was described by Darwin as the 'pupa.' The skin of the pupa moults off, certain changes of position take place, and the permanent structure and activities of the adult are gradually assumed. The external firm shell of the rapidly growing adult cannot, of course, be moulted, but at frequent periods the whole lining of the shell and the skin of the legs is shed (see SKIN-CASTING). These cast coats are exceedingly common, especially during the spring months. Darwin quotes an observation of Mr C. W. Peach, who notes their extraordinary abundance, and says, 'he could easily have filled several quart measures with them.'

The acorn-shells feed on small marine animals. They are attached not only to rocks, but to floating objects and to other animals. Numerous species are known, of which *B. improvisus* inhabits brackish water. The sessile *Balanidae* differ from the stalked *Barnacles* (q.v.) or *Lepadidae* only in detail; in both families the waving legs are borne by the thorax, and they were therefore classed by Darwin, in his famous memoir of the Cirripedia, in the sub-order Thoracica. Some of the larger

species of *balanus* were esteemed by the Romans, and are still eaten by Chinese and others. *B. psittacus* sometimes measures 4 inches in

Acorn-shells in the skin of a whale.
(From Bronn's *Thier-Reich*.)

diameter, and *B. tintinnabulum* is also large. See Darwin's *Monograph of Corripedia* (2 vols. 1851-54); Huxley's *Invertebrata*.

Acorus. See CALAMUS.

Acosta, GABRIEL, or **URIEL D'**, a Portuguese of noble Jewish birth, was born at Oporto about 1594. Brought up a Catholic, he early adopted the faith of his fathers, and fled to Amsterdam, only to find there how little modern Judaism accorded with the Mosaic Law. For his *Examination of Pharisaic Traditions* (1624), a charge of atheism was brought against him by the Jews before a Christian magistracy; and having lost all his property, twice suffered excommunication, and submitted to humiliating penance, he at last shot himself (1640). His autobiography was published in Latin and German (Leip. 1847).

Acotyle'donous Plants—i.e. without seed-leaves or cotyledons—a term first emphasised by A. L. de Jussieu, who included all the plants now known as cryptogams under the title *Acotyledones*. They include Algæ, Fungi, Liverworts, Mosses, Ferns, Horsetails, Lycopods (q.v.), and are contrasted with the conifers, monocotyledons, and dicotyledons, which produce seeds containing an embryo with rudimentary root, stem, and leaves. The term is no longer in use. See CRYPTOGAMIA.

Acoustics (Gr. *akouo*, 'I hear') is sometimes used for the science of sound in general, which in this work is treated at SOUND, but more commonly for the special practical branch of that science which deals with the construction of public halls, churches, &c. so as to secure the accurate hearing of speech or music. It must be confessed that, in this practical sense, the science is still in its infancy. It is very easy, in general, to point out the causes of acoustic defects in a building *once it has been erected and tried*; it is quite another matter to predict from the plans what are likely to be its defects; except, of course, when some flagrant violation of simple principles has been perpetrated. One reason for this is obviously the want of data on which to reason, due to the enormous cost which would be involved in a thorough experimental treatment of the subject. The consequence is that when by chance one successful attempt has been made, architects prefer to copy it rather than to attempt some new form, which might probably entail complete failure.

The improvement of the acoustic properties of a building must be determined by the ascertained defects, so that no general rules can be laid down. One great point is the prevention of echoes, unless these reach the ear almost at the same moment with the original sound. This can be effected in many cases by lowering the ceiling so as to expedite the echo; also by hanging carpets or heavy tapestry on the walls, and especially in the corners of the building. These have the effect of

abolishing it. Idiotic attempts are constantly being made nowadays to secure the same results by stretching wires about in various directions. Such devices betray absolute ignorance of the mode of propagation of sound.

Acquaviva, a town of Bari, South Italy, in a healthy situation at the foot of the Apennines, on the Bari and Taranto Railway, 28 miles SSE. of the former town. Pop. 12,000.

Acqui (Lat. *Aquæ Statiellæ*), a town of Northern Italy, 21 miles SSW. of Alessandria by rail. It derives its name from its hot sulphur springs, which were known to the Romans. The town contains an old castle, a Gothic cathedral (12th century), and remains of a Roman aqueduct. Wine and silk are produced. Pop. 15,000.

Acquiescence is the name applied to an important principle of equity in the law of both England and Scotland. It means either (1) the failure for a length of time to take an objection, of which the party is aware, to an invalid or challengeable agreement, or a set of accounts; or (2) the failure to object to any important proceeding by another person, involving expense and difficulty of restoration, in such circumstances that it is fair to conclude that the person failing to object has tacitly agreed to his property or other rights being dealt with. Acquiescence closely resembles the Scottish doctrine of *rei interventus* in the law of contracts, and also to some extent the doctrine of estoppel by conduct in the law of England.

Acras'peda. See JELLYFISHES.

Acre, a word (from A.S. *acer*) which is identical with Gothic *akr-s*, Ger. *acker* ('a cultivated field'), Lat. *ager*, Gr. *agros*, Sansk. *ajras*. Most nations have, or had, some measure nearly corresponding; originally, perhaps, the quantity which one plough could plough in a day. The English statute acre consists of 4840 sq. yards. The chain with which land is measured is 22 yards long, and a square chain will contain 22 × 22, or 484 yards; so that 10 sq. chains make an acre. The acre is divided into 4 roods, a rood into 40 perches, and a perch contains 30½ sq. yards. Before the fixing of the statute acre (Act 5, George IV. c. 74) the acre varied in different parts of the country, and still survives locally in several counties; it varies in size from 2·115 statute acres in Cheshire to 0·477 in Leicestershire. The old Scotch acre is larger than the English, the Irish than the Scotch; 23 Scotch acres = 29 imperial acres; 30½ Irish acres = 49 imperial. The hectare (nearly 2½ acres; see ARE) of the French metric system has on the Continent superseded almost all the ancient local measures corresponding to the acre—such as the Prussian *morgen*.

English acre.....	1·00
Scotch ".....	1·27

Acré, or **AQUIRY**, a tributary of the Purús, gives its name to a rubber-producing Brazilian territory (60,000 sq. m.; pop 100,000), a subject of dispute with Bolivia till 1903.

Acre, **ST JEAN D'**, or **ACCA**, the Biblical *Accho*, a seaport of Palestine, 80 miles NNW. of Jerusalem, and 27 S. of Tyre. Population, 10,000. The harbour is partly sanded up, yet is one of the best on this coast. It was named Ptolemais from King Ptolemy Soter of Egypt. Taken by the Crusaders in 1110, it was recovered in 1187 by the Sultan Saladin; but retaken in 1191 by Richard I. of England and Philip at a cost of 100,000 men.

The town was now given to the Knights of the Order of St John, who kept it by constant fighting for a hundred years. In 1517 it was captured by the Turks; in 1799 it was besieged by the French for sixty-one days, but was successfully defended by the garrison, aided by a body of English sailors and marines under Sir Sidney Smith. In 1832 it was stormed by Ibrahim Pasha, son of the viceroy of Egypt, and continued in his possession till it was bombarded and taken, in 1840, by a combined English, Austrian, and Turkish fleet. The British took it in September 1918. It is a centie of the Bahai movement.

Acri, a town of South Italy, 13 miles NE. of Cosenza; pop. 4000.

Acrididae. See LOCUST.

Acrobat literally signifies one who walks on tiptoe (Gr. *akron*, 'extremity', *bainō*, 'I go'), and designates one who performs difficult feats, vaulting, sliding, tumbling, and dancing on a slack or tight rope, stretched either horizontally or obliquely. These feats require great skill, suppleness, and steadiness. The extraordinary skill of some performers has given this perilous art a great celebrity. Within modern times Farioso, Madame Saqui, and Signor Diavolo have excited admiration by their marvellous agility; Blondin was even more widely known. The acrobats of antiquity appear to have closely resembled those of our own day.

Acroceraunia, a promontory of Albanian Epius, jutting out into the Ionian Sea, the termination of the Montes Ceraunii. This range derived its name from the frequent thunder-storms which occurred among its peaks (Gr. *keramos*, 'thunder'). The coast of the Acroceraunia was dangerous to ships; hence Horace in a well-known ode speaks of its 'ill-famed rocks.' Its mountains are alluded to by Shelley in his poem *Arethusa*.

Acrocomia. See PALM.

Acrogens (Gr., 'summit-growers'), a term applied to the higher cryptogamic plants in which root, stem, and leaf are usually distinctly developed—e.g. ferns, club-mosses, horsetails, &c. The name refers to the structure and growth of the stem in which the vascular bundles when present are 'simultaneous' (see STEM) in development, and growth occurs only at the apex, while increase in thickness is effected by the coherence of leaf-bases or the formation of roots. Of this 'acrogenous' growth, tree-ferns are the best examples. The term has, however, fallen into disuse, along with the terms Exogen and Endogen (q.v.), on account of the erroneous views of dicotyledonous and monocotyledonous stem-growth which these latter respectively imply.

Acrolein, $\text{CH}_2\text{:CH}\cdot\text{CHO}$, an unsaturated aldehyde. It is a colourless liquid, boiling at 126°F . (52°C). It constitutes the acrid principle produced by the destructive distillation of fatty bodies, and is in part due to the decomposition of glycerine. It is prepared by distilling glycerine with a dehydrating agent, potassium-hydrogen sulphate being generally employed. Two molecules of water are removed, acrolein being left, $\text{C}_3\text{H}_5(\text{OH})_3 = \text{C}_3\text{H}_4\text{O} + 2\text{H}_2\text{O}$. In its state of vapour, it is extremely irritating to the eyes, nostrils, and respiratory organs—a property to which it owes its name. The pungent smell given off by the smouldering wick of a candle just blown out is due to the presence of acrolein. When mixed with a solution of potash or soda, the irritating odour disappears, and is replaced by an odour of cinnamon, while a brown resinous substance is formed; and certain oxidising agents, as oxide of silver, convert it into *acrylic acid*, $\text{C}_3\text{H}_3\text{COOH}$.

Acroliths (Gr. *akron*, 'extremity', and *lithos*,

'a stone'), the name given to the oldest works of Greek plastic art, in which wood-carving is seen in transition into marble statuary. The trunk of the figure is still, in the old style, of wood, covered with gilding or with actual cloth drapery; but the extremities—head, arms, feet—which are meant to appear naked from below the drapery, are of stone. Compare the *chryselephantine* statues.

Acromegaly, a disease characterised by overgrowth of the face, hands, feet, and other parts. See PITUITARY BODY.

Acropolis, 'the high-town,' was, in many of the important cities of Greece and Asia Minor, the name of the citadel. It usually occupied the summit of a rock or hill, and was fortified, commanding the city and its environs. It contained some of the most important public buildings, especially temples, besides affording a last refuge in case of a hostile attack. The acropolis, like the castle of the middle ages, formed the centre or nucleus around which the town gradually grew. Notable amongst these old Greek strongholds were the Acropolis of Argos; that of Messene; that of Thebes, called Cadmea; that of Corinth, known as Acro-Corinthus; but especially that of Athens, which was styled pre-eminently the Acropolis, and contained the Parthenon, the Erechtheum, and other famous buildings. See ATHENS.

Acrostic (Gr., made up of *akros*, 'pointed, first,' and *stichos*, 'a row'), a term for a number of verses the first letters of which follow some predetermined order, usually forming a word—most commonly a name—or a phrase or sentence. Sometimes the final letters spell words as well as the initial, and the peculiarity will even run down the middle of the poem like a seam. Sir John Davies composed twenty-six *Hymns to Astrea* (Queen Elizabeth), in every one of which the initial letters of the lines form the words ELISABETHA REGINA. The following is one of the twenty-six:

E very night from ev'n to morn,
L ove's chorister amid the thorn
I s now so sweet a singer;
S o sweet, as for her song I scorn
A pollo's voice and finger.

B ut, nightingale, sith you delight
E ver to watch the starry night,
T ell all the stars of heaven,
H eaven never had a star so bright
A s now to earth is given.

R oyal Astrea makes our day
E ternal with her beams, nor may
G ross darkness overcome her;
I now perceive why some do write
N o country hath so short a night
A s England hath in summer.

One of the most ancient and remarkable acrostics is the phrase in Greek, 'Jesus Christ, the Son of God, the Saviour,' the initial letters of which form the word *ichthys*, 'fish,' to which a mystical meaning was attached (see SYMBOL). In Hebrew acrostic poetry, the initial letters of the lines or of the stanzas were made to run over the letters of the alphabet in their order. Twelve of the psalms of the Old Testament are written on this plan. The 119th Psalm is the most remarkable. It is composed of twenty-two divisions or stanzas (corresponding to the twenty-two letters of the Hebrew alphabet), each stanza consisting of eight couplets; and the first line of each couplet in the first stanza beginning, in the original Hebrew, with the letter *aleph*, in the second stanza with *beth*, &c. The divisions of the psalm are named each after the letter that begins the couplets, and these names have been retained in the English translation. With a view to aid the memory, it was customary at one time to compose verses on sacred subjects

after the fashion of those Hebrew acrostics, the successive verses or lines beginning with the letters of the alphabet in their order. Such pieces were called *Alphabetical Hymns*.

Acroterion (Gr., 'the summit'), a term for a statue or other ornament placed on the apex or at one of the lower angles of a pediment. Some understand by acroterion, the pedestal on which such ornament stands.

Act has various technical meanings, legal and other. The phrase 'act in the law' means generally an act which is fitted and designed to have a distinct legal effect. It includes a document in writing, as when a person executing a legal instrument declares it to be his *act and deed*. Or it may be the record of an act or proceeding of a public nature, as an Act of Parliament (q. v.). This use of the word is derived from the Romans.

ACT OF BANKRUPTCY, in English Bankruptcy Law, is any act which subjects a person to be proceeded against as a bankrupt. Such acts are equivalent to the marks of notour bankruptcy in Scots law. See **BANKRUPTCY**.

ACT OF GOD is a legal expression, and signifies any occurrence not caused by human negligence or intervention, such as storms, lightning, tempests, the consequences of which no party under any circumstances (independently of special contract) is bound to make good to another. The chief applications are in the law of carriage of goods, where Act of God is an exception to the liability of the carrier, and in the law of contract, where Act of God often excuses from performance.

In the United States, an act signifies something done for which the person doing is responsible; something done by an individual in his private capacity, or as an officer; or by a body of persons, as an association, corporation, legislature, or court. It includes not only physical acts, but also decrees, orders, resolutions, and laws. An act indicates intention. In criminal matters, an act does not make the actor criminal unless the intention was criminal. An act is also an instrument in writing to verify facts. A public act is one that has public authority, made public by authority, or attested by a public seal; one pertaining to the whole community, while a private act operates upon particular persons and private concerns.

Act, in the Drama, is a distinct section of a play, in which a definite and coherent part of the plot is represented. It is generally subdivided into smaller portions called *scenes*, and its conclusion is properly marked by a fall of the act-drop or curtain. As every dramatic plot naturally divides itself into three parts—the exposition, the development, and the conclusion or catastrophe—a division into three acts would seem most natural, and has accordingly been adopted in modern comedies. But it has been found inconvenient to inclose extended plots in such limits, and since the earliest days of tragedy, *five* acts have generally been considered necessary for its satisfactory development.

Act of Congress. See **CONGRESS**.

Act of Parliament. See **PARLIAMENT**.—For the Acts of Settlement, of Toleration, of Uniformity, and the Test Acts, see **SETTLEMENT**, **TOLERATION**, **UNIFORMITY**, and **TEST ACTS** respectively.

Acts of Sederunt, ordinances of the Court of Session or supreme civil court in Scotland, made originally under authority given by King James V. in 1532, and ratified by the Scots Act, 1540, chap. 93, whereby the judges are empowered to make such rules or ordinances as may be necessary for the regulation of legal procedure and the expediting of

justice. The court passed a great number of acts prescribing the forms of process in both superior and inferior courts. Acts of parliament frequently allow or direct the Court of Session to make rules in the form of Acts of Sederunt with a view to carrying out the statutory provisions. In certain cases the rules are laid on the table of parliament, and, if not rejected by parliament, have the authority of an act of parliament. The rules in election petitions, the fees of law-agents and burgh registrars, the examination of law-agents, and other matters are regulated by Acts of Sederunt. The Report of the Scottish Judges to the House of Lords in 1810 shows that this power of regulation was formerly extended to legislation by the judges; but no such power is now claimed. In 1913 the Court of Session passed a codifying Act of Sederunt consolidating and amending previous acts, and repealing all inconsistent therewith.

Acts of the Apostles, the fifth book of the New Testament, from which we derive most of our knowledge of the history of the apostolic age. The book commences with an account of the earliest Christian community at Jerusalem, and concludes with a brief reference to the visit of St Paul to Rome. It has often been suggested that 'From Jerusalem to Rome' would be a more fitting title for the book, since it would more aptly describe its contents. The chief problems connected with the book are those of *authorship*, *motive*, *date*, and *historical value*. On the question of *authorship*, the investigations of Harnack have done much to re-establish the traditional view that it was the work of Luke 'the beloved physician.' Harnack lays stress on the passages written in the first person plural—the 'we-passages,' as they are called—and adduces evidence to prove that the rest of the book is the work of the same hand. *Motive*.—Modern scholarship has rejected the extreme forms of the 'tendency-theory' advocated by Baur and Zeller. The main motive of the book was historical—to supply information to Theophilus, who was probably a Roman official. Incidentally, however, the writer attempts to use the story as an encouragement to the Christians of his own day, and to show by use of illustrations that the Roman empire had in the earliest period always been a protector of the Christian religion. *Date*.—Harnack has revived the theory that the book was written almost immediately after the point at which the narrative breaks off—i.e. about 62 A.D. Otherwise, he argues, the abrupt ending of Acts seems inexplicable. Most modern scholars, however, seem to prefer a date about 80 A.D.; while some, on the ground that certain passages seem to imply the use of Josephus, date it as late as 100. *Historical Value*.—The investigations of Sir W. Ramsay have demonstrated the remarkable accuracy of the geographical and historical details in the second part of Acts. The description of the status of the civic officials in each town has been proved to be true by the evidence of inscriptions, &c. In the earlier chapters, however, the character of the narrative appears to be less trustworthy. The account of the tongues at Pentecost seems to conflict with the statements of the Epistles, and many scholars think that the references to Theudas and Judas in Gamaliel's speech are an anachronism.

See Harnack, *Luke the Physician*; Ramsay, *St Paul the Traveller*; Chase, *Credibility of Acts*; Zeller, *Acts of Apostles Critically Examined* (1876); Commentaries by Wendt (in German), Rackham (Westminster Commentaries), Knowling (Expositor's Greek Testament), Bartlett (Century Bible); Andrews (Westminster New Testament).

Actæa. See **BANEBERRY**.

Actæon, the hunter, who, having surprised Diana bathing, was changed by the goddess into a stag, and so torn to pieces by his own dogs.

Acta Sanctorum (Acts of the Saints), the collective title usually given to various ancient works on the saints and martyrs, both those of the Greek and Roman Catholic churches, but now applied especially to one great collection begun by the Jesuits in the 17th century, and continued by the Bollandists (q.v.). For other collections, see SAINT, MARTYR.

Actinia. See ANEMONE.

Actinism (Gr. *aktis*, 'a ray of sunlight') is a term whose signification has varied considerably. It seems to have been invented by Sir J. Herschel (about 1824), and with him it was used to express the heating-power of sunlight. His Actinometer was employed for the same purposes as the Pyrheliometer (q.v.). Later the term was applied to the property—which certain rays of light (alone) appeared to possess—of decomposing chemical compounds (see SPECTRUM and PHOTOGRAPHY). Recent discovery has proved that there is no special class of actinic rays, it being found possible to utilise any of them photographically by proper physical and chemical processes. See HEAT.

Actinium, a name given to a radio-active element which Debierne separated from pitchblende (before the discovery of radium), and which he held to be responsible for the radio-activity of impure thorium. See RADIUM.

Actinolite, a calcium-magnesium-iron Amphibole (q.v.) generally occurring in columnar or fibrous masses of greenish colour. It may be considered a variety of Tremolite (q.v.).

Actinomyco'sis, a disease of cattle long since noted, but for many years confounded with tubercle or sarcoma. In 1877 Bollinger of Munich showed that little yellow grains are always present, consisting of a minute fungus, with its mycelium arranged in a radiate manner. To this fungus he gave the name Actinomyces; and further observation has confirmed his view that it is the cause of the disease (ray-fungus). It is most common in cattle, occurs also in pigs, and (rarely) in man. It consists of tumours, sometimes of large size, formed of inflammatory material deposited round numerous grains of the fungus. They frequently suppurate and break down. In cattle they occur usually in the jaws, mouth (woody tongue), and stomach; in man in the neck, lungs, and adjacent parts.

Actinozoa (Gr. *aktis*, 'a ray,' and *zōon*, 'an animal'), one of the three classes of Coelenterates, including sea-anemones, dead-men's fingers, corals, &c. Like all Coelenterates, they possess a central mouth and digestive cavity, and are provided with Stinging Cells (q.v.); but they are distinguished from the other two classes (Hydrozoa and Ctenophora) by the possession of a turned-in mouth-tube, forming a stomach region distinct from the body-cavity, and by the presence of a definite number of radial partitions extending from the inner tube to the body-wall. They are provided with tentacles round the mouth, and live either isolated or in colonies. The generative products are always formed on the cross partitions or mesenteries above referred to. The Actinozoa include two orders—Alcyonaria or Octacoralla, with eight tentacles; and Zoontharia or Hexacoralla, with tentacles in sixes. Of the former, Alcyonium, or dead-men's fingers, is a convenient type; and the sea-anemone is a familiar representative of the latter, to which the vast majority of corals also belong. See ALCYONIUM, ANEMONE, CORAL.

Action, in its large sense, means a judicial proceeding before a competent tribunal for the attainment of justice; and in this sense it is applied to procedure, whether *criminal* or *civil*. In its more limited acceptation it is used to signify proceedings in the *civil* courts, where it means the form pre-

scribed by law for the enforcement of a right. Thus in England the word is defined by the Judicature Act, 1873, as a 'civil proceeding commenced by writ, or in such other manner as may be prescribed by rules of court.' The procedure in actions in the High Court of Justice is mainly regulated by the Judicature Acts of 1873 and 1875, and by the rules of the Supreme Court, which are made by the judges under powers conferred on them by these acts. The High Court of Justice has all the powers of a Court of Common Law and a Court of Equity; and the rules of procedure formulated for actions in that court have in various ways assimilated the common law and the equity procedure, selecting the good points of both. Criminal proceedings in the King's Bench Division which are commenced by information or indictment are not 'actions'; nor can that term properly be applied to matters coming before the court on what are called 'motions,' which are mere summary applications made to the court. In Scotland the formal distinction between law and equity never obtained. In certain civil actions the Court of Session has exclusive jurisdiction; in certain cases its jurisdiction can be exercised only in the way of review. But the great majority of civil actions may in Scotland be brought in the first instance either in the Court of Session or in the Sheriff Court. Actions in Scotland were never confined to the same rigid *formulae* in original writ and subsequent pleading as in England. Now, however, there is no very substantial difference between the course of an action in England and in Scotland. The first step is to bring the defending party into court by service of a summons; the next to ascertain by a record or adjusted pleadings what is the question at issue; the next to ascertain by argument, evidence, or both which party is in the right—a judgment on a question of law being generally subject to appeal, while the verdict of a jury on a matter of fact is generally final. In England, under the Judicature Acts, the defending party has a much larger power of bringing forward a counter-claim than in Scotland, and can even obtain decree in his favour if the counter-claim exceeds the original claim. Every action includes many incidental matters, such as motions to recover documents, to sist new parties, to amend, &c. The expenses of an action are generally ordered to be paid by the losing party, subject, however, to audit or taxation by an officer of court. See COMMON LAW (COURTS OF), and EQUITY.

Actium, a promontory on the west coast of Greece, at the entrance of the Ambracian Gulf, memorable for the naval victory gained near it by Octavian (afterwards the Emperor Augustus), over Mark Antony and Cleopatra, which decided the fate of Rome and of the world, 2d September 31 B.C. The two armies were encamped on the opposite shores of the gulf. Octavian had 80,000 infantry, 12,000 cavalry, and 250 ships of war; Antony, 100,000 infantry, 12,000 cavalry, and 500 ships. Antony's ships were large, and well provided with engines for throwing missiles, but clumsy in their movements; Octavian's were smaller and more agile. It was the advice of Cleopatra that decided Antony to rest the issue on a sea-fight. The battle continued for some hours undecided; at last, Agrippa, who commanded Octavian's fleet, succeeded, by a skilful manœuvre, in compelling Antony to extend his line of battle, the compactness of which had hitherto resisted all attempts of the enemy to break through. Cleopatra, who was stationed behind Antony's line, in terror took to flight with her sixty ships, and Antony at once flung away the empire of the world, and recklessly followed her with a few of his ships. The deserted fleet continued to resist bravely for some time, but was finally vanquished.

Acton, a borough of Middlesex, just beyond the western boundary of the county of London, whose population (61,314 in 1921) more than doubled between 1891 and 1911.—**ACTON BURNELL** is a parish 8 miles SE. of Shrewsbury, with the ruins of the castle where, in 1283, the parliament was held which passed the 'Statute of Merchants.'

Acton, **SIR JOHN FRANCIS EDWARD** (1736-1811), minister of Ferdinand IV. of Naples, was the son of an English physician, and was born at Besançon. Acquiring distinction in the naval service of Tuscany, he became admiral and generalissimo in that of Naples, and soon managed the entire administration. His measures, able but arbitrary, ultimately caused a reaction against the royal family of Naples, and in favour of the French party; and he fell from power in 1806.—His grandson, **JOHN EMERICH EDWARD DALBERG-ACTON**, **LORD ACTON** (1834-1902), was born at Naples, and succeeded his father as baronet in 1837. He was educated at Oscott under Cardinal Wiseman, and at Munich by Dr Dollinger, whose views he zealously espoused, distinguishing himself in Rome in 1870 by his hostility to the dogma of papal infallibility. He sat in parliament for Carlow (1859-65), and was raised to the peerage by Mr Gladstone in 1869. Leader of English Liberal Catholics, he was for a time editor of the *Home and Foreign Review*, and afterwards of the *Weekly Chronicle* and *British Quarterly*; but it was rather by his universal repute as a scholar of singular learning and breadth of mind than by his writings on the Vatican decrees (1874), Wolsey (1877), German Schools of History (1886), and other occasional publications, that he had shown himself exceptionally well qualified to hold the Cambridge chair of History as Seeley's successor (1895). His inaugural lecture on *The Study of History* expounded the high and deep view he took of the subject. The inherent worth and interest of humanity was his leading thought; the course of history was for him a philosophy of history. His erudition was vast and his insight profound. But his lofty ideal of fastidious accuracy limited his productiveness. No scholar of anything like his learning wrote or published so little; perhaps his chiefest bequest to posterity was his planning the great *Cambridge Modern History*. His enormous library, purchased after his death by an American millionaire, and presented to Lord Morley, found an appropriate resting-place in the university of Cambridge.

See *Lord Acton and his Circle*, by Cardinal Gasquet (1906); his *Lectures on History* (1906); *Freedom and Other Essays*, and another volume of *Essays* (1907).

Actuary, a word that in England, like *actuarius* in ancient Rome, once meant the clerk or registrar who recorded the *acta* or business of public bodies—as it still does in the convocation of the province of Canterbury. It was also used for a notary, and till the 19th century for the managing secretary or accountant of a company. Now it means a member of the profession whose calculations supply the principles of life assurance, annuity, and reversionary business; the actuary's functions are the application of the doctrine of probabilities to the affairs of life. The Institute of Actuaries of Great Britain and Ireland was founded in 1848; the Faculty of Actuaries in Scotland in 1856; the Actuarial Society of America in 1889. See **ANNUITY**, **INSURANCE**, **PROBABILITIES**.

Acupressure, a mode of arresting hemorrhage from cut arteries, introduced by Sir James Y. Simpson. It consists in the insertion of a needle through the tissues on both sides of the bleeding vessel, so that the elasticity of the tissues, aided sometimes by a wire firmly looped round the projecting ends of the needle, presses the

artery against the needle and closes its tube. It is now rarely used; and only under special circumstances. Acupressure has also occasionally been used in the treatment of Aneurism (q.v.).

Acupuncture (Lat., 'pricking with a needle') is a very ancient remedy, and one practised extensively in the East, for the cure of headaches, lethargies, &c. In Europe it is principally employed to relieve neuralgic pains, and those of chronic rheumatism. Steel needles are made use of, about three inches long, and set in handles. The surgeon, by a rotatory movement, passes one or more to the desired depth in the tissues, and leaves them there from a few minutes to an hour. Their insertion is accompanied by no pain, except the first prick—a fact the quacks of the 16th century did not fail to take advantage of. According to Jerome Cardan, they travelled from place to place practising acupuncture, and before inserting the needle, they rubbed it with a peculiar kind of magnet, either believing or pretending that this made the operation painless. The relief to pain afforded by this simple operation is sometimes astonishing, and the wounds are harmless if care be taken to avoid large vessels. Needles protected except at their points by insulating material are sometimes used as conductors of the galvanic current to deep-seated parts. For the use of hollow needles in the administration of medicines, see **HYPODERMIC INJECTION**. See also **NEURALGIA**.

Ada, a town of the Bachi (Bács-Bodrog), on the river Theiss, a trading town and import station for steamers; pop. 12,500.

Adagio (It.), a slow or very slow movement or measure of time in Music. In the more extended compositions of orchestral or chamber music, the second or third *movement* is generally marked *adagio*, and serves as a contrast to the rapid and energetic movement of the preceding and following parts of the sonata or symphony. The distinctive feature of the *adagio* being its power of expression, it affords the most direct means to the composer of manifesting his individuality of feeling. The finest specimens of the *adagio* are found in the works of the old masters, above all in Beethoven. In recent works, our composers have generally succeeded better in their rapid movements than in the *adagio* (see **SYMPHONY**).

Adal is the name of the flat and barren country lying between the Abyssinian plateaux and the Red Sea, from Massowa to the Bay of Tajurra, its greatest width being 300 miles. The native tribes are of the same stock as the Danakil, and are Mohammedans.

Adalbert, St., the apostle of the Prussians, was a native of Prague, and was chosen its bishop in 982. His austerity irritated the lawless and but recently converted Bohemians, and he was obliged to flee from his diocese. Soon after his return, he left it anew to carry the gospel to the Hungarians. He afterwards preached without much success to the heathen Poles and Prussians, and was murdered by the latter, 23d April 997. His body was buried in the cathedral at Gnesen, and afterwards carried to Prague; and here, in 1880, his bones were discovered in a vault and re-interred in the cathedral.

Adalbert, a great German ecclesiastic, born of a noble family about 1000, was appointed Archbishop of Bremen and Hamburg in 1045, and papal legate to the north in 1053. He soon extended his spiritual sway over Scandinavia, and carried Christianity to the Wends. In 1063 he became tutor of the young Henry IV., and soon, spite of the opposition of the nobles, ruled over

the whole kingdom. His ambitious mind now conceived the design of founding a great northern patriarchate, which should vie with the Roman curia itself; but he died too soon for his vast design, at Goslar, March 16, 1072.

Adalia, anciently *Attalia*, a growing seaport on the south coast of Asia Minor, at the head of the Gulf of Adalia. Pop. 30,000.

Adam and Eve, the names of the first pair of human beings in the account of the creation given in the book of Genesis. 'Adam' is strictly a generic name, applicable to both man and woman, as used in Genesis, chapter i.; but it came to be a proper name used with the article, as in chapters ii., iii., and iv. The origin of the name is uncertain, but is usually connected with the Hebrew root *Adam*, 'to be red.' It is often derived from *Adamah*, 'the ground,' but this is taking the simpler from the more developed form. The Assyrian equivalent is *Adamu*, 'man,' used only in a general sense, not as a proper name. This is connected by Sir Henry Rawlinson and Professor Sayce with *Adamatu*, 'red skins,' the Assyrian word by which the dark-skinned Accadians of primitive Babylonia are designated in the bilingual tablets. Eve is the Hebrew *Havvah*, which name, according to Gen. iii. 20, Adam gave her as the 'mother of all living.' Literally the word means 'life.'

The early part of Genesis contains two somewhat different accounts of the creation of Adam. In the earlier account (i. 26-30), the creation of man and woman is given after the creation of the animals; in the second account (chapter ii.), the creation of Adam is mentioned before that of the animals, and the forming of Eve afterwards. The first narrator is commonly called the Elohistic, from his use of the name *Elohim* for 'God;' the second, the Jehovistic, from his using the name *Jehovah Elohim*. The Elohistic narrator simply states that God created man in his own image. Man is created at the close of the six days' work as the lord of the whole lower world, for whom all things are made. The Jehovistic narrator gives a detailed account of Paradise, the original sin of Adam and Eve, their subjection to the curse, and expulsion from Eden (q.v.). It is, in Ewald's phrase, the 'history proper of the creation of man.' The first condition of Adam and Eve is one of innocent simplicity. They are placed in Eden, where they are allowed to taste freely of the fruit of every tree save one. Temptation comes from without, through the serpent's persuading Eve that the divine prohibition is really intended to keep human beings from becoming as wise as God. Eve yields to the temptation, and leads Adam also into her sin; and thus the moral consciousness of man awoke, and spiritual death passed upon mankind. Adam and Eve are then driven out of Paradise, and prevented by the cherubim and a flaming sword which turned every way, from returning 'to take also of the tree of life, and eat, and live for ever.' Adam lives 930 years; has three sons, Cain, Abel, and Seth, then sons and daughters.

Such is the form of the story which has usually been interpreted by orthodox Jews and Christians as a narrative of literal history, notwithstanding many difficulties about the anthropomorphic details and the admitted uncertainty of the point where the literal ends and the figurative begins. Many of the later Jews explained the story as an allegory. Philo, the foremost writer of the Alexandrian school, explains Eve as the sensuous part, Adam as the rational part, of human nature. The serpent attacks the sensuous element, which yields to the temptation of pleasure, and next enslaves the

reason. Clement and Origen adapted this interpretation somewhat awkwardly to Christian theology. Augustine explained the story as history, but admitted a spiritual meaning superinduced upon the literal; and his explanation was adopted by the Reformers, and indeed generally by the orthodox within the Komish and the various Protestant churches alike. More modern critics have sought to separate the kernel of history from the poetical accretions, and attribute the real value of the story, not to its form, but to the underlying thoughts. Martensen describes it as a combination of history and sacred symbolism, 'a figurative presentation of an actual event.' The narrative may be regarded as embodying the philosophy of the Hebrew mind applied to the everlasting problem of the origin of sin and suffering; a question the solution of which is scarcely nearer us now than it was to the primitive Hebrews. It is not the form of the story which is material here, but the substance and the meaning; and the elemental truth of the fall of man by misuse of his free-will remains a religious fact, apart altogether from the historical form in which the fact is stated. In the Pauline theology Adam stands as the covenant head or federal representative of the whole human race in contradistinction to Christ, 'the second man,' 'the last Adam.' See FALL.

Egyptian, Babylonian, and Persian accounts.—The fundamental ideas of pantheism and emanation, which formed the basis of the great religions of the ancient world, were perfectly consistent with a vague theory of the origin of man, which explained him as having issued somehow from the very substance of divinity itself by a kind of spontaneous generation—a development of the chain of emanations—rather than as the result of a free act of a creative will. Such is the account in the *Sanchoniathon*, a fragment of a Phœnician cosmogony that has reached us in a Greek version. Egyptian accounts explain that the fertile slime left by the Nile, under the vivifying influence of the heat of the sun's rays, sprouted into the bodies of men; or as expressed in mythological form, men sprung from the eye of the sun-god. This emanation produced the material body, but a later demiurgic process moulded the form to beauty and communicated to it a soul. Various nations were thus formed by different goddesses: the Egyptians—the highest race in the world—were moulded by the supreme demiurge, Khnoum. One very detailed Babylonian account of the creation is preserved in the Greek of Berosus (q.v.). According to it there was a time when there was nothing but darkness and an abyss of waters, inhabited by a monstrous brood of composite creatures, over which presided a woman named Omoroca ('the sea,' *Tiamat*). Bel cut this woman asunder, making of her lower half the earth, and of her upper half the heavens, while he destroyed all the creatures within her. He next cut off his own head, on which the other gods kneaded the blood as it gushed out with earth, and from it formed men. Hence it is that they are rational and partake of divine knowledge. Next he formed, in the same way, the animals, then the stars, the sun, the moon, and the five planets. Here, leaving out the polytheistic element, the facts follow the same order as in the narrative of the Jehovistic author of Genesis.

Another account, deciphered from the cuneiform inscriptions, has a striking resemblance to the story in the first chapter of Genesis, but it is questioned by Sayce whether this account was translated into Assyrian from an older Accadian document, or in its present form is older than the 7th century B.C. Unfortunately only portions of it exist. It would appear that in these inscriptions the events of each of the days' work were recorded on a special tablet,

and that the numbers of the tablets generally followed the same order as the days of creation in Genesis. Thus, the first, which gives an account of Chaos and the generation of the gods, corresponds closely with the first two verses of the first chapter of Genesis, even to the same word being used in both narratives as the name of the *Chaos*. The fifth tablet, giving the creation of the heavenly bodies, is the most recognisable portion, and is closely parallel to the fourth day of creation in Genesis; while the seventh corresponds with the sixth day. Another tablet refers to the creation of man, ascribing it to Hea, as in all the references in other inscriptions. An early tablet from Nippur, now in Philadelphia, was found by Dr Langdon in 1914 to preserve part of a Sumerian hymn to the creatress Nintud, giving the story of the fall and the flood. Noah, or Tagtog, a gardener, is cursed by Nintud for eating of the cassia tree. In Babylonian monuments the serpent frequently occurs; and from his epithets is evidently an embodiment of moral evil. An archaic Babylonian gem represents a tree, on either side of which are seated a man and woman, with a serpent behind the latter, and their hands are stretched out towards the fruit that hangs on the tree; but Schrader warns us that here there is not the slightest indicated reference to what constitutes the specific feature of that narrative—the presentation of the fruit by the woman to the man. The palm may be recognised as the prototype of the ‘sacred tree’ as represented on the Assyrio-Babylonian monuments. Somewhat similar mystic trees were the Haoma of the Iranians, and the Soma in India.

The religion of Zoroaster is the only one of the ancient religions other than the Jewish which ascribes the creation to the free-will of a personal god, distinct from primordial matter. Ahuramazda, the good and great god, creates the universe and man in six successive periods of a year. The first man is Gayōmaretan. In the Pehlevi *Bundehesh*, the cosmogony goes further. Here both a man type and a bull type are formed, who live for 3000 years on the earth, until the latter is destroyed by Angromainyus, representing the evil principle. Next the man also falls, but from his body after forty years springs a stalk, from which blooms a creature of double body, both male and female, which Ahuramazda divides into two, and so forms Maschya and Maschyana, the couple from whom descend the whole human family.

It was a common opinion that man was created both male and female in one body, and that the two sexes were separated to form man and woman. This is taught by many of the Rabbis, and is suggested by Aristophanes in the *Symposium* of Plato, to explain the passion of love, which is merely a craving of the incomplete and imperfect for its original completeness and perfection. Lenormant endeavours to show that this is borne out by Gen. i. 28, and chap. v. 2, and the interpretation has the authority of Jewish tradition, as well in the Targums and Talmud, as in scholars like Moses Maimonides, and Eusebius of Caesarea.

Greek, Polynesian, Zulu, and other accounts.—An ancient Greek account represents Prometheus as making the first man out of earth, or clay and water, and then quickening him with fire stolen from heaven; but earlier accounts limit his work to the latter function, and make men spring up out of the soil. Hesiod describes man in his primitive state as free from sickness and evil before Prometheus stole fire from heaven, and Pandora, who corresponds to Eve, brought miseries to the earth. Prometheus gives man the capability of knowledge; his daring theft is for man the beginning of a fuller and higher life. Æschylus regards Prometheus as

the representative of humanity, led into misery by his self-will, until he submits to the higher will of God. This corresponds with the story of Genesis, save that in the latter the spiritual features are clearer and more distinct.

In Scandinavian mythology, the gods draw the first men from the trunks of trees. In many primitive mythologies, the first man is synonymous with the deity, himself his own creator. The theory of family manes, carried back to tribal gods, leads us naturally upwards to a divine ancestor, or first man. Among the Polynesians, men are sprung from the divine Maui, the Raratongan Tiki, the Tii of the Society Islands, whose son Taata (‘man’) precisely represents a Polynesian Adam, the ancestor of the human race. In the mythology of Kamchatka, one of the sons of Kutka, the creator, is Haetsh, the first man, who after his life on earth descends into Hades to be lord of the under world. The Brazilian tribes refer their origin to Tamoi, the grandfather, the first man, who after living on earth and teaching men to till the soil, ascended to the sky, there to receive the souls of his descendants as they die. The Hindu Yama is not only the first created man, but the first who died, the ‘first to show us the way when our course is run, and our sun sets in the far west.’ In later Indian theology, he becomes also the awful Judge of the dead, who assembles the souls of men in a house appointed to them for ever. The supreme god of the Dacotah Indians is the creator Unkayhee, who after he had finished the making of the world, took one of his own divine offspring, and grinding him to powder, sprinkled it upon the earth. This produced many worms which matured into infants to become full-grown Dacotahs. Similarly, the Jouskeha of the Iroquois was at once creator of the world and father of the human race; and the gods of the Quiches of Guatemala, Tohil, discoverer of fire, Avilisa and Kacavitz, were apotheosised men, who were actual progenitors as well as ancestral deities. The Zulus carry their worship of the manes of the dead back into tribal deities (Unkulunkulu), and beyond these to the original race deity and creator, the First Man—he who ‘broke off in the beginning,’ the Old-old-one, the great Unkulunkulu.

Later Jewish, Gnostic, and Moslem Versions.—In Rabbinical and Moslem theology, the first man has hardly more than a place of precedence in Hades or in heaven. Yet even here we find traces of the universal tendency to deify an ideal ancestor; for the Rabbinical Adam is a gigantic being reaching from earth to heaven. Rabbi Jehuda says that as he lay stretched out on earth he covered it completely. Eve’s proportions were correspondingly large. When he was first created, the angels stood in awe of him, and all creatures hastened to worship him. Then God caused a sleep to fall on Adam, and removed a portion of every limb. Thus he lost his vast stature, but remained perfect in every part. His first wife was Lilith; but she fled from him when Eve was created. At the marriage of Adam and Eve, who were of course endowed with every grace, angels were present, some playing on musical instruments; while the sun, moon, and stars danced together. The happiness of the human pair excited envy among the angels, and the seraph Sammael tempted them, and succeeded in bringing them to their fall. The Targum of Jonathan makes Eve created from the thirteenth rib of Adam’s right side; and thus he was furnished with one rib more than any of his descendants. According to the Koran, all the angels paid homage to Adam, except Eblis, who, on account of his refusal, was expelled from Paradise. To gratify his revenge, he tempted them to sin. In the system of the Christian Gnostics,

Adam, the primal man, stands as earthly representative of the Demiurge, and ranks as one of the highest Æons.

Some have tried to establish from the double account of the creation in Genesis that there were two creations of man—the first, a defective race which peopled the whole Gentile world; the second, Adam, from whom the Jews were specially descended. The argument for the pre-Adamite creation will be found in a curious book published in 1655 by Isaac de la Peyreire, a converted Jew, who afterwards, for safety's sake, recanted his errors at Rome.

Science and the Unity of Man.—The question of the unity of man has caused much controversy. The old chronology was set aside when geology and archeology made it manifest that man existed on the earth many thousands of years ago. This discovery removed the chief difficulty of the *monogenists*, who had to account for the great varieties in the present races of men as having sprung from one common stock within a limited period of time. The *polygenists* pointed to the remarkable permanence of type, in spite of the differentiating conditions of climate and circumstance, to prove that such races as the Negroes, Mongolians, and Whites were distinct species—each sprung from a separate origin in its own region. But fuller knowledge of savage man has demonstrated the essential identity in the working of his mind as well as the structure of his body with the most cultured races; and experience has shown that all the present races, in spite of form and colour, are capable of forming crossed races of every combination. Moreover, the modern doctrine of evolution, or the development of species, has confirmed the monogenist theory in insisting against constituting separate species where the differences are moderate enough to be accounted for as due to variation from a single type.

The question of the original unity or diversity of language is not, however, necessarily identical with that of the unity of the human race. For, even allowing mankind to have descended from a single pair, language might not have originated till long after they had passed away; and the formation of language may not have taken place at once, but may have been a gradual process going on for ages. However this may be, the faculty of speech is still one grand mark of distinction between man and the brute; and the fact remains that no anthropoid ape has ever raised himself to the level of articulate-speaking man.

The story of Adam has been a rich subject both in literature and art. It was frequently treated by the mediæval painters, and formed the material of many mysteries and other poems. Of more modern works, it is enough to mention the splendid epic of Milton, *Paradise Lost*. Here Adam and Eve are the archetypal man and woman, sketched with outlines that can only be compared for grand simplicity with Michael Angelo's two frescoes in the Sistine Chapel, of Adam and of Eve coming into life.

See Tylor's *Primitive Culture* (1871); Darwin's *Descent of Man* (1871); Haeckel's *History of Creation* (trans. by Ray Lankester, 1876); Peschel's *Races of Man* (trans. 1876); Baudissin's *Studien zur Semitischen Religionsgeschichte* (1876-78); De Quatrefages' *The Human Species* (trans. 1879); Professor Sayce's edition of George Smith's *Chaldean Account of Genesis* (1880); vol. i. (1882) of Lenormant's *Les Origines de l'Histoire d'après la Bible*; Schrader's *Keilinschriften und das Alte Testament* (2d ed. 1883; Eng. trans. vol. i. 1885); Sayce's *Introduction to the Science of Language* (2d ed. 1883); and Euchtha's *Mélanges de Critique Biblique* (1886).

Adam of BREMEN, an old historical writer, whose work entitled *Gesta Pontificum Hammen-burgensium* gives a history of the archbishopric of Hamburg from 788 A.D. to the death of the

Archbishop Adalbert in 1072. It has great historical value; besides notices of ecclesiastical affairs, it gives accounts of the northern Slavonic tribes, which the author collected during a visit to the Danish king Svend-Estrithson. Adam was canon and *magister scholarum* at Bremen from 1069 to the time of his death, which took place in 1075.

Adam, ADOLPHE CHARLES, musical composer, was born in Paris on July 24, 1803, and died in 1856. He was professor of Composition in the Paris Conservatoire from 1848, and also contributed considerably to the newspapers. His best works are his comic operas, among which the chief is the *Postillon de Longjumeau*, produced in 1835, which still keeps the stage as a popular work. He was the successor to the style of Boieldieu, but the frequent triviality of his music marks a stage of the decline of French comic opera to the lower level of opera-bouffe.

Adam, ALEXANDER, LL.D., was born near Forres, Elginshire, 24th June 1741. The son of a small farmer, he had to struggle through much hardship in the pursuit of learning; but in 1757 he came to Edinburgh University, and in 1761 obtained the head-mastership of Watson's Hospital, and in 1768 the rectorship of the High School. This post he filled for nearly forty years with distinguished ability and success, raising the reputation of the school beyond what it had ever been before. Scott, Horner, and Jeffrey were among his pupils. In some of his reforms he encountered such opposition as now seems almost fabulous. He published a new Latin grammar (1772), written in English; but the town-council prohibited him from teaching it. His *Roman Antiquities* (1791) was the work which did most to promote his reputation, and for many years was the best manual of the kind in existence. His *Summary of Geography and History* appeared in 1794, his *Classical Biography* in 1800, and his *Latin Dictionary*—an abridgment of a larger work unfinished at his death—in 1805. On 18th December 1809 he died of apoplexy, his last words being: 'But it grows dark, boys; you may go.'

Adam, JEAN, a Scottish poetess, was born near Greenock in 1710, and died in the Glasgow poor-house in 1765, after a joyless life, first as school-mistress, then as lawker. Her *Poems* (1734), religious effusions in the Tate and Brady style, by no means support the claim advanced for her to the authorship of 'There's nae Luck about the House,' which, with much more likelihood, is ascribed to Mickle. See a long article in *Athenæum* for 27th January 1877.

Adam, ROBERT, a distinguished architect, was born at Kirkcaldy in 1728. His father, William Adam of Maryburgh, Fife, who died in 1748, was also an architect of no mean repute. After leaving Edinburgh University, Robert Adam proceeded in 1754 with Clérissieu, a French architect, to Italy, and thence to Dalmatia, where he made drawings of the ruins of Diocletian's palace at Spalatro. On his return to Britain, in 1762, he was appointed architect to the king. In opposition to the heavy style of architecture then prevalent, he introduced a taste for lightness and decoration, which, however, tended to the opposite extreme of weakness and triviality. In 1768 he was elected member for Kinross-shire. During upwards of twenty-five years, his practice, in partnership with his brother James, was more extensive than that of any other architect. In 1773 the brothers commenced to publish a series of engravings of their chief designs, which was completed by a posthumous third volume in 1822. Robert died in London 3d March 1792, and was buried in Westminster Abbey. In

Edinburgh his principal works are the Register House, and the main block of the University buildings, which last were completed only in 1887 by the addition of a graceful dome. Glasgow owes its Infirmary to him; and London, the Adelphi buildings (so called after the two *brothers*) and the screen to the Admiralty. Other works were Caenwood House, Kedleston Hall, Luton House, Lansdowne House. See books by Swarbrick (1916) and Bolton (1922).—His nephew, the Right Hon. WILLIAM ADAM of Blair-Adam (1751–1839), sat in parliament as a Whig from 1774 to 1811, and in 1816 was appointed chief-commissioner of the Scottish jury court. He was father of JOHN ADAM (1779–1825), Anglo-Indian statesman, of Admiral Sir CHARLES ADAM (1780–1853), and of General Sir FREDERICK ADAM (1781–1853); whilst Sir Charles was father of WILLIAM PATRICK ADAM (1823–81), for six years Liberal 'whip,' and then governor of Madras for the last few months of his life.

Adam's Apple, the popular name given to the projection in the fore-part of the neck formed by the anterior extremity of the thyroid cartilage of the larynx; so called from the notion that it was caused by a bit of the forbidden fruit which stuck in Adam's throat. The same name is applied to the fruit of a variety of the lime with a kind of depression on the surface, in which the Italian peasants see the mark of Adam's teeth. The name is also used for the Forbidden Fruit (q.v.).

Adam's Bridge, a chain of sand shoals 30 miles long, extending from a small island off the Indian coast to one just off Ceylon. It greatly obstructs navigation of the channel. A ferry connects the railways of India and Ceylon.

Adam's Peak, the name given by Mohammedans, and after them by Europeans, to a mountain summit in the south of Ceylon, 7420 feet high (not, however, the highest of the group). The native name is Samanella. The cone forming the summit is a naked mass of granite, terminating in a narrow platform, in the middle of which is a hollow, five feet long, having a resemblance (increased by human agency) to a human footstep. Mohammedan tradition makes this the scene of Adam's penitence, after his expulsion from Paradise; he stood 1000 years on one foot, and hence the mark. To the Buddhists, the impression is the *Sri-pada*, or sacred footmark, left by Buddha on his departure from Ceylon; and the Hindus recognise Buddha as an avatar of Vishnu. Multitudes of devotees, Buddhist, Hindu, and Mohammedan, visit the mountain.

Adamant, a term now used to express any substance of extraordinary hardness, chiefly a rhetorical or poetical word. The name was attached to a supposed stone or mineral, as to the properties of which vague notions long prevailed. It was identified with the lodestone or magnet, and was often used as synonymous with it by early writers. This confusion ceased with the 17th century, but the word for a long time had a currency among scientific writers as a synonym with diamond. The original of the word is the Gr. *adamas*, originally an adjective meaning 'invincible,' afterwards used as a name of the hardest metal, and also applied by Theophrastus to the hardest crystalline gem then known—the emery-stone of Naxos. Sir J. Murray says that the early medical Latin writers (apparently explaining the word from *adamare*, 'to take a liking to,' 'have an attraction for') took the *lapideum adamantem* for the lodestone or magnet (an ore of iron, and thus also associated with the ancient metallic sense); and with this confusion the word passed into the modern languages.

Adamantine Spar. See CORUNDUM.

Adamawa, an African territory lying between the Cameroons and Boinu. Anglo-German agreements (1885–90), defining the boundaries between the territory of the Royal Niger Company and German Kamerun, divided Adamawa between them, the larger share falling to Germany. Since 1900, when the company's territories were taken over by the British government, the British part of Adamawa, including Yola, the capital, is in northern Nigeria (q.v.). Amid the southern mountains rise numerous streams, the most important being the Benue (q.v.), which waters the entire province. The people, who are Mohammedans, are active, industrious, and intelligent.

Adamites, a 2d-century Gnostic sect in Africa, who sought to recall the state of innocence men were in before the fall, rejected marriage, and went naked. Part of their doctrines were in the middle ages adopted by some of the Beghards or Brethren of the Free Spirit; especially in Bohemia and Moravia, where Ziska slew large numbers of them.

Adamnan, Columba's biographer, was born about 625, of the race of Hy-Neill, in that part of Ulster which now forms the county of Donegal. Educated at the monastic seminary of Clonard, in his 28th year he joined the Columban brotherhood of Iona, of which, in 679, he was chosen abbot, the ninth in succession to his great kinsman, the founder. In 686 he paid a visit to his friend and pupil, Aldfrid, king of Northumbria, to procure the release of some Irish captives; and during this visit, and another one two years later, he was converted to the Roman views as to the holding of Easter and the shape of the tonsure. Those views he endeavoured to inculcate in Iona, and also in Ireland, which he twice revisited, in 692 and 697; but he failed, at least in Iona, and it is said that mortification at the failure caused his death, which befell on 23d September 704, the day of his translation in old Irish and Scottish calendars. He left behind him a Latin treatise 'On the Holy Places' of Palestine and other countries, dictated, he says, by Arculfus, a Frankish bishop, who, returning from a pilgrimage, had been wrecked on the Western Isles. It is valuable as one of our earliest descriptions of Palestine; and three editions of it were published between 1619 and 1734, and one in 1889 (ed. G. J. R. Macpherson). *Adamnan's Vision*, a professed account of his visit to heaven and hell, is preserved in an Irish MS. of the 12th century, but was certainly written by a later hand (10th or 11th century; see Boswell's *Fis Adamnain*, 1909). A work of surpassing interest that is certainly his is the *Vita Sancti Columbæ*, his Life of Columba. Along with miracles and many stories palpably incredible, this book reveals a great deal of distinct and minute matter concerning the remarkable community to which both the author and his hero belonged. The standard edition, from an 8th century codex found at Schaffhausen in 1845, was edited by Dr Reeves in 1857 for the Bannatyne Club (q.v.), and the Irish Archaeological Society, which (with trans.) forms the sixth vol. (1874) of *Scottish Historians*. Most of our knowledge about the early Scoto-Irish Church is comprised in that volume. Another edition of the life is that by Dr Fowler (Oxford 1895).

Adams, CHARLES FRANCIS, an American diplomatist, the son of John Quincy Adams, was born in Boston on the 18th of August 1807. He passed his childhood mostly in St Petersburg and London, graduated at Harvard, studied law, and was admitted to the bar in 1828. He served for five years in the legislature of Massachusetts. He was nominated at Buffalo, in August 1848, for the office of vice-president by the convention of Free-soilers. In 1858, and again in 1860, he was elected to congress for Massachusetts. In 1861 he was

appointed minister to England, where he acquitted himself with credit in the difficult and important controversies that arose between his government and Great Britain during the great civil war in the United States. He resigned this office in 1868, was an arbitrator in the Alabama claims tribunal at Geneva (1871-72), and died 21st November 1856. He published the *Life and Works of John Adams* (10 vols. 1850-56), his *Letters to his Wife*, and the *Diary of J. Q. Adams* (12 vols. 1876-77). There is a *Life* of him by his son (1900).

Adams, JOHN, the second president of the United States, was born in Braintree, about 10 miles from Boston, in the then British colony of Massachusetts Bay on the 19th of October 1735, old style. He was the eldest son of John Adams, a farmer in comfortable circumstances, and distinguished himself at Harvard College. He at first intended to become a minister, but the orthodox teachings of that day 'drove him from the profession of divinity to that of the law.' After his graduation in 1755, he was master of a school for three years at Worcester, Massachusetts, studying law meanwhile, and was admitted to the bar in 1758. For the practice of the law, he was pre-eminently qualified by these natural endowments—a sound constitution of body, a clear and sonorous voice, a ready elocution and intrepid courage, characteristics which served him in excellent stead in the stormy political career which he was destined to pass through.

In 1768 Adams removed from Braintree to Boston—then a town of about 16,000 inhabitants—where he soon acquired 'more business at the bar than any other lawyer in the province.' Soon after his settlement in Boston, the Attorney-general of the province (an officer of the crown) tendered him the post of Advocate-general in the Court of Admiralty, an offer which his ardent sympathies with the colonists, as against the crown, constrained him to decline. Important questions touching the rights and duties of the colonies under the crown were at this time being freely debated, and Adams is credited with having struck the key-note of the revolution which separated the colonies from the mother-country, by protesting before the governor and council in 1765, against the enforcement of the Stamp Act, and against any right of parliament to tax the colonies without their consent. Although one of the most resolute and prominent of the advocates of the popular cause, he appears never to have countenanced or encouraged those violent excesses of the colonists which ended in coercive measures on the part of the crown; and when, in March 1770, some soldiers stationed in Boston fired on a mob and killed several persons, his sense of duty induced him to imperil his popularity by acting as counsel for the soldiers, who were tried for murder. In the same year the people of Boston elected him a member of the general court (the legislature); but his health failing, he withdrew from public life, and removed his residence, in 1771, to Braintree. Meanwhile he was chosen one of the five delegates from Massachusetts to the first Continental Congress, which met in Philadelphia in September 1774.

Here he found a fit arena for the exercise of those great talents, both for business and debate, which ultimately raised him to the leadership of that body. He proposed and secured the election of George Washington as commander-in-chief of the Continental Army; he carried (May 1776) a resolution that the colonies should assume the duty of self-government; and on the 7th of June seconded a motion made by Richard Henry Lee, of Virginia, that these colonies 'are and of right ought to be free and independent states.' The support on the

floor of congress of this motion and of the 'Declaration of Independence' which followed, devolved mainly upon Adams, who, in the face of a sturdy opposition, acquitted himself with such ability as to lead Jefferson to style him 'The Colossus of that debate.'

The public duties which devolved upon Adams after the passing of the Declaration of Independence in congress are reported as something enormous. He was appointed president of the Board of War, and a member of upwards of ninety committees, of twenty-five of which he was chairman. He records that he was kept constantly at work from four o'clock in the morning until ten at night. After months of these incessant labours, he was granted a long vacation in the winter of 1776-7, and finally retired from congress in November of the latter year. He was, however, immediately appointed a commissioner at the court of France, from which he returned in 1779, and took part in a convention to frame a constitution for the state of Massachusetts. In November he again embarked for Europe, armed with powers from congress to negotiate a treaty of peace and commerce with the mother-country (with which the colonies were still at war); but the object of his mission becoming known at Paris, the jealousy of the French ministry was aroused, and through their influence his powers were revoked. He next visited Amsterdam, in an endeavour to interest Dutch capitalists in the cause of his country; and in January 1781 he was authorised to represent the colonies at the court of Holland. Meanwhile a new commission, consisting of Adams and four coadjutors, had been appointed by the American congress to settle the terms of peace between the United States and the mother-country, and on the 3d of September 1783 the treaty was signed. In 1785 Adams was appointed minister to England, a position which he held until he was recalled, at his own request, in 1788. While in London, he published his *Defence of the Constitution and Government of the United States* (3 vols. 1787).

In 1789 he became vice-president of the United States—General Washington being inaugurated president. Washington and Adams were re-elected in 1792; and at the close of their administration in 1796, Adams was chosen president by the Federalists—Thomas Jefferson, the republican candidate for the presidency, becoming vice-president. An administration chiefly noted for fierce dissensions among the leaders of the Federal party, especially for a bitter hostility between Adams and Alexander Hamilton, was followed by the defeat of Adams (who had become a candidate for re-election) in 1800, and the election of Jefferson and Aaron Burr, the democratic candidates, as president and vice-president. Chagrined at his defeat, and burdened with a sense of what he deemed his undeserved unpopularity among the members of his own party, Adams now retired to his home at Quincy, Massachusetts, where he passed the remainder of his life in comparative obscurity. He died July 4, 1826.

See *Works of John Adams*, edited by his grandson, C. F. Adams (10 vols. 1850-1856); *Life of John Adams*, by J. Q. Adams and C. F. Adams (2 vols. 1871); *John Adams* (American Statesmen Series), by John T. Moise, jun. (1885).

Adams, JOHN COUCH, discoverer, simultaneously with Leverrier, of the planet Neptune, was born near Launceston in Cornwall, 1819. He was sent in 1839 to St John's College, Cambridge, where, in 1843, he attained the honour of senior wrangler, and became a mathematical tutor. Soon after taking his degree, he undertook to find out the cause of the irregularities in the motion of Uranus, anticipating, indeed, his own and Leverrier's dis-

covery—that they are due to the influence of a then unknown planet. Leverrier did not commence his researches till the summer of 1845; but on the 10th of November published the results of his calculations, assigning to the unknown planet almost the same place as Adams had done in a paper which he left with the Astronomer Royal at Greenwich Observatory in the previous October, but which he neglected to publish. Leverrier thus acquired a larger share in the honour of the discovery; but the merit of Adams is not less, and the council of the Royal Astronomical Society awarded equal honours to both in 1848. Neptune was actually observed, near the place assigned, by Galle at Berlin in September 1846. In 1858 Adams was appointed to the Lowndean Professorship of Astronomy, Cambridge. He made important researches as to the secular acceleration of the moon's mean motion, on the November meteors, and on other subjects. He died at Cambridge, 21st January 1892. See his *Scientific Papers* (edited by W. G. Adams, with Life by Glaisher, 1896-98), and Professor H. H. Turner's *Astronomical Discovery* (1904).

Adams, JOHN QUINCY, an American statesman, the son of President John Adams, and himself the sixth president of the United States, was born in the parish of North Braintree (now Quincy), in the colony of Massachusetts Bay, July 11, 1767. When eleven years old, he accompanied his father on a diplomatic journey to Paris, and at the age of fourteen became private secretary to Francis Dana, the envoy from the United States to St Petersburg. He was secretary to the commission which negotiated the treaty of peace between the colonies and the mother-country; but when, in 1785, his father received the appointment of minister to the court of St James's, Adams returned to America, and entered the junior class of Harvard College. He graduated in 1787, studied law, and was admitted to the bar in 1790. In 1794 he received from President Washington the appointment of minister resident at the Hague; was afterwards sent to the court of St James's was nominated by Washington as minister to Portugal; and on the accession of the elder Adams to the presidency, was appointed minister to Prussia. In 1802 he was chosen state senator by the Federalists of his district, and in 1803 was elected to the United States senate from Massachusetts. Here he gradually rose into a position of influence, though often jeopardising his popularity with his own party by acting with the opposition.

In 1806 he boldly denounced in the senate the right claimed by the British government of searching and confiscating the cargoes of neutral vessels bound for countries with which the British were at war, and introduced resolutions (which were supported by the republicans) requesting the president to demand the restoration of property so confiscated. This position thoroughly alienated Adams from the Federal party, and the Massachusetts legislature expressing its disapproval of his course by prematurely electing his successor, he promptly resigned his seat in the senate. In 1809 he was appointed minister to St Petersburg by President Madison; in 1814, was chosen a member of a commission to negotiate a treaty of peace between Great Britain and the United States, and in the following year became minister at the court of St James's, where he remained until he was recalled in 1817 to assume the duties of secretary of state under President Monroe. In the latter capacity he negotiated with Spain a treaty for the acquisition of Florida by the United States, and for the settlement of the western boundary of Louisiana; and it is claimed that to him belongs the paternity of that policy which denies the right of interference by

European governments in the affairs of the American continents, familiarly known as 'The Monroe Doctrine.'

On the close of Monroe's administration in 1825, Adams was elected president by the House of Representatives—no election having been made by the people. An uneventful administration followed. Failing of an election for a second term, he retired to his home at Quincy, depressed, unhappy, and poor in purse. In 1830 he was elected by the National Republican (afterwards the Whig) party to the lower house of congress, where he became particularly noted as a promoter of the growing anti-slavery sentiments of the Northern States; was ever ready to defend the abstract right of petition, and subjected himself to severe reproaches by constantly laying before the house floods of petitions for the abolition of slavery. One of the ablest of the old school of statesmen, he was returned to each successive congress until his death, which occurred in the Speaker's room of the House of Representatives, February 23, 1848.

His *Memoirs*, comprising portions of his diary (1795-1848), were edited by his son, Charles F. Adams, in 12 vols.; his *Writings* by W. C. Ford (12 vols. 1913 *et seq.*). See *Lives* by John T. Morse (1882) and W. O. Stoddart (1887).

Adams, SAMUEL, American statesman, was born at Boston, U.S., September 27, 1722, and graduated at Harvard. He was destined for the Congregationalist ministry, but by his father's misfortunes was obliged to engage in business, which he presently exchanged for a collectorship of taxes. He displayed on all occasions an unflinching zeal for popular rights, and in 1765 was elected by the patriotic party a member of the Massachusetts legislature. He played a prominent part as deputy of his native state in the Philadelphia congress, and signed the Declaration of Independence (1776). He took an active share in framing the constitution of Massachusetts, and was for several years president of its senate. He held the office of its lieutenant-governor from 1789 to 1794, and of governor from that time till 1797. He then retired from public life, and died at Boston, October 2, 1802, poor as he had lived. Adams was somewhat narrow-minded and bigoted, both in religion and politics. He was prejudiced against Washington, whose conduct of the war his ignorance of military matters led him to think weak and dilatory. In 1776 he anticipated Napoleon by applying the term, 'a nation of shopkeepers,' to the English. See his *Life*, by Wells (3 vols. Bost. 1865), and Morse (Bost. 1884).

Adams, THOMAS, a notable Puritan preacher, of whose personal history few details are precisely known. From 1612 till about 1653 he held charges in Bedfordshire, Buckingham, and London. His most notable works are his sermons and his commentary on 2d Peter. Southey called him 'the prose Shakespeare of Puritan theologians.'

Adams, WILLIAM, an English navigator, who was born in 1564 at Gillingham, near Chatham, and who from 1600 till his death in 1620 was resident in Japan, where he was 'in such favour with two emperors as never was any Christian in those parts of the world.' See his *Letters* in vol. i. of *Purchas his Pilgrimes*; his *Log*, ed. Purnell (Japan Soc. xiii.); also the *Diary* of Richard Cocks (1883).

Adams, WILLIAM, was born in 1814, and died in 1848 at Bonchurch in the Isle of Wight, having been an Oxford tutor and clergyman (1837-42). He was author of *The Shadow of the Cross* and three other beautiful 'Sacred Allegories,' as also of *The Cherry Stones*, &c.

Adana, a city of SE. Asia Minor, on the Sihun, 30 miles from the sea, commands the pass of the Taurus Mountains, is on the Bagdad railway-line,

and has cotton-mills. Cotton, cereals, wool, chrome, and copper are local products. In 1909 terrible riots and massacres of Christians took place. The victims were about 2000 in the town and 15,000 to 25,000 in the neighbourhood. Pop. 50,000.

Adanson, MICHEL (1727-1806), born at Aix, left clerical studies for natural history, and at twenty-one went to Senegal, whence after five years he brought back a large collection of botanical specimens. In 1757 he published his *Histoire Naturelle du Sénégal*, and in 1763 his *Familles des Plantes*, in which he endeavoured to give a new form to botany, the classification being based on the similarity of the several organs of the plants; but he could not prevail against the established Linnæan system. An encyclopædia planned by him received little substantial encouragement. During the Revolution he fell into great poverty; afterwards he received a pension.

Adansonia. See BAOBAB.

Adaptation, a term applied in biology to any particular fitness in structure or in function which adds to effectiveness in given conditions. Adaptations are to be seen throughout the whole organism—in the architecture of bone, in the structure of the heart, in protective coloration, in the so-called mechanism which brings about warm-bloodedness, in the distribution of regenerative capacity, in immunity to certain poisons, in the shapes of leaves, in the flower's arrangements which secure cross-fertilisation, and so on endlessly. Sometimes the term is used in reference to the evolutionary process by which the adaptive result has been brought about, whether by the selection of inborn variations (Darwinism) or by the hereditary accumulation of acquired modifications (Lamarckism). See DARWINIAN THEORY, EVOLUTION.

Adda (Lat. *Addua*), a river of Lombardy, rising in the Rhaetian Alps, flows through the Lake of Como, traverses Lombardy, and falls into the Po 8 miles above Cremona, after a course of 180 miles.

Addah, a seaport, at the mouth of the Volta, in eastern Gold Coast.

Addams, JANE, born in 1860 at Cedarville, Illinois, has lectured on and greatly promoted social reform, and written on *Democracy and Social Ethics*. In 1889 she and Miss Starr opened the famous Social Settlement of Hull House at Chicago.

Adder. See VIPER, PUFF-ADDER.—The very venomous *Death or Deaf Adder* of Australia (*Acanthophis antarctica*) is found in hot sandy districts.

Addington. See SIDMOUTH.

Addis Ababa, better ADIS ABABA, a place which, dating only from 1892, was soon thereafter made capital of Abyssinia by Menelek, stands in the south of Shoa, on the southern slopes of the Entoto range, draining to the Hawash; pop. 50,000. A railway to Djibouti is under construction.

Addiscombe, a place in Surrey, near Croydon. A mansion here was, in 1812-61, the East India Company's college for cadets.

Addison, JOSEPH, was born on the 1st of May 1672. He was the eldest son of Lancelot Addison, then rector of Milston, in Wiltshire, and afterwards dean of Lichfield, and of Jane, his wife, daughter of Dr Nathaniel Gulston. He was educated at Amesbury, at the grammar-school in Lichfield, and afterwards at the Charterhouse, from which, in his sixteenth year, he passed to Queen's College, Oxford. Having obtained a demyship at Magdalen, he proceeded to his Master's degree in 1693, and in the same year began his literary career with a poetical address to Dryden. Next year appeared his *Account of the Greatest English Poets*, and a translation of the

fourth book of the *Georgics*, with an Essay on that poem. Through Dryden, he became acquainted with Jacob Tonson, the publisher, and by him was introduced to Charles Montague and Somers, at whose suggestion, probably, he wrote in 1695 his complimentary *Address to King William*. In 1697 he was elected probationary fellow of his college, and would in the regular course have been obliged to take orders, had not Montague, who wished him to enter political life, prevailed on the president not to insist on the fulfilment of this condition. Through the influence of Montague, he obtained in 1699 a pension from the crown of £300, for the purpose of enlarging his experience by continental travel. He spent four years in France, Italy, Austria, Germany, and Holland, during which period he wrote his *Letter to Lord Halifax*, and made notes for his *Remarks on Several Parts of Italy*, and his *Dialogue on Medals*. He returned to England in the autumn of 1703. His chief patron, Halifax, having been removed by Queen Anne, on her accession, from the Privy Council, he was now without hope of political advancement, and was apparently reduced to a state approaching poverty, when he was invited by the ministry, acting on the advice of Halifax, to commemorate in verse the victory of Blenheim. This was the origin of *The Campaign*, written in 1704, in return for which he received a commissionership of appeal in Excise.

In 1706 he was promoted to be under-secretary of state, first to Sir Charles Hedges, and, after his removal, to the Earl of Sunderland. While acting in this capacity, he produced his opera *Rosamond*, which was performed, but without much success, in April 1706. In 1707 he attended Lord Halifax to the court of Hanover, whither the latter was sent to carry the Act for the Naturalisation of the Electress Sophia. When the Earl of Sunderland was replaced in 1708 by Lord Dartmouth, Addison found himself without employment, but he was almost at once appointed by Lord Wharton, who at that time became lord-lieutenant of Ireland, to the post of secretary. In this year he was also elected member of parliament for Lostwithiel, and on that election being invalidated, was chosen to represent Malmesbury. While he was secretary in Ireland, he formed a warm friendship with Swift, who frequently mentions him with affection in his *Journal to Stella*, and regrets the estrangement which afterwards grew up in consequence of their party differences. He also contributed largely to the *Tatler*, which had been started by his friend Steele in 1709; 41 papers being wholly by Addison, and 34 by him and Steele conjointly. The Whig ministry fell in the autumn of 1710, and Addison had to vacate his appointment, though he was allowed to keep, apparently through Swift's influence, the keepership of the records in Bermingham's Tower, a place worth £400 a year. In March 1711 was founded the *Spectator*, 274 numbers of which, namely those signed with one of the letters C L I O, were the work of Addison.

His fortune was now so much augmented, that in 1711 he was enabled to purchase for £10,000 the estate of Bilton, near Rugby. While he was on his travels, he had written four acts of his tragedy, *Cato*, which his political friends, perceiving that it would be valuable for party purposes, persuaded him in 1713 to finish for the stage. It was acted on the 14th of April 1713, and in consequence of the vehement party-spirit of the times, aroused such enthusiasm, that it kept the stage for thirty-five nights. When the Treaty of Utrecht was signed, Addison, in promotion of Whig interests, attacked its commercial policy in a pamphlet called *The Late Trial and Conviction of Count Tariff*. These party services gave him great consideration with the Whigs, and on the death of Queen Anne in August

1714, he was named secretary to the lord-justices appointed provisionally to administer affairs. After the accession of George I., he became once more secretary to the Earl of Sunderland as lord-lieutenant of Ireland, holding the appointment till August 1715. In this year, a suspicion that he was the author of Tickell's translation of the first book of the *Iliad*, brought him into collision with Pope, who afterwards satirised him in the famous character of Atticus, declaring, in all probability falsely, that he had actually sent the verses to Addison himself. He also wrote his comedy of *The Drummer*, which was acted without success at Drury Lane; and, in order to reconcile the nation to the accession of the House of Brunswick, at the instigation of the government he started the *Freeholder*, which was continued from December 23, 1715, to June 9, 1716. He was soon afterwards made one of the commissioners for trade and colonies, and in August 1716, married Charlotte, Countess of Warwick. A report, in all probability unfounded, as it is inconsistent with the mention of the Countess in Addison's will, says that the marriage was an unhappy one. In April 1717 he was appointed secretary of state, but resigned his post, owing to his failing health, in March 1718. Almost his last literary undertaking was unfortunately a paper-war, on the subject of the Peerage Bill of 1719, with his old friend Steele, whose attack on the bill in a series of pamphlets called the *Plebeian*, was answered by Addison in the *Old Whig*. He was suffering at the time from asthma; dropsy soon after supervened; and he died at Holland House, on the 17th of June 1719, at the age of 47.

Addison's literary genius must be judged from different points of view. As a poet, his capacity is very moderate. *The Campaign* professes to be no more than an unadorned recital in verse of Marlborough's exploits; *Cato* is written with great elegance and correctness, but is wanting in dramatic spirit; the *Letter to Lord Halifax* has many fine verses, particularly in the apostrophe to Liberty. As a light essayist he has no equal, and scarcely a second, in English literature. It was his object to form a sound public taste, and to recover the nation from the distracted intellectual state into which it had fallen after the Restoration, by preserving the morality of the Puritans without their fanaticism, and the elegance of the court without its licentiousness. The noble monument of his success is the *Spectator*, a paper in which the foundations of all that is sound and healthy in modern English thought may readily be traced. As an 'abstract and brief chronicle' of the manners of the time, it is incomparable, and the name of Sir Roger de Coverley alone is associated with one of those creations which are instinctively selected as characteristic of the English genius and language. Addison's criticism does not aim at being profound; but in its sobriety and good sense, it afforded precisely the antidote which the age required against the extravagant conceits and false wit which had found favour with the 17th century. The praise of his prose style has been written by Johnson, and it is not exaggerated; his manner reflects the peculiar character of his humour, a singular grace and breeding being conveyed in sentences full of subtle irony, which are balanced without being formal, and though constructed with apparent simplicity, defy mechanical imitation. See the *Life*, by Lucy Aikin (1843), and Macaulay's review of it; also the present writer's *Addison* (1884).

Addison, THOMAS, physician, was born near Newcastle in 1793, and graduated in medicine at Edinburgh in 1815. He settled in London, and in 1837 became physician to Guy's Hospital, where

he was almost equally eminent as investigator and as clinical lecturer. His chief researches were on pneumonia, phthisis, and especially on the Supra-renal Capsules (q.v.) and the somewhat rare disease of those organs since known as *Addison's Disease*. The discovery of this disease was a piece of sound original work, though of no great practical importance. He also wrote on poisons, on the disorders of females, and, with Dr Bright, *Elements of the Practice of Medicine* (vol. i. 1839). He died 29th June 1860.

Addison's Disease. See SUPRARENAL CAPSULES.

Addorsed, or ADDOSSÉ, a heraldic term signifying turned back to back.

Address, FORMS OF. The following are the correct ceremonious modes of addressing and beginning letters to persons of title or holding offices:

Ambassador, British—Address: 'His Excellency [in other respects according to his rank], H.B.M.'s Ambassador and Plenipotentiary.' Begin: 'Sir,' 'My Lord,' &c., according to rank. Refer personally to as 'Your Excellency.' An Ambassador's wife, when resident abroad, is sometimes, but not very correctly, designated 'Your Excellency.'

Archbishop—'His Grace the Lord Archbishop of —.' Begin: 'My Lord Archbishop.' Refer to as 'Your Grace.' In formal documents the Archbishop of Canterbury is addressed as 'The Most Reverend Father in God, Randall Thomas, by Divine Providence Lord Archbishop of Canterbury, Primate of all England and Metropolitan;' the Archbishop of York as 'The Most Reverend Father in God, Cosmo, by Divine permission Lord Archbishop of York, Primate of England and Metropolitan.' But an Irish Archbishop appointed since 1868 is only 'The Most Reverend the Archbishop of —,' unless he happen to be a temporal peer, in which case he is 'The Right Hon. and Most Rev.'

Archdeacon—'The Venerable the Archdeacon of —.' Begin: 'Venerable Sir.'

Baron—'The Right Hon. Lord —,' or 'The Lord —.' Begin: 'My Lord.' Refer to as 'Your Lordship.'

Baron's Daughter—If unmarried, 'The Hon. [Christian name and surname]. If married, 'The Hon. Mrs. [husband's surname]. Begin: 'Madam.' If married to a Baronet or Knight, 'The Hon. Lady' [husband's surname]. Begin: 'My Lady.' If the wife of a peer, or of the son of a Duke or Marquess, address as such.

Baron's Son—'The Hon.' [Christian name and surname]. Begin: 'Sir.' But the eldest sons of Barons in the Peerage of Scotland are usually addressed as 'The Hon. the Master of' [peerage title].

Baron's Son's Wife—'The Hon. Mrs.' [husband's surname], or, if necessary for distinction, the husband's Christian name should also be used. Begin: 'Madam.' If the daughter of an Earl, Marquess, or Duke, address as such.

Baroness, either in her own right or her husband's—'The Right Hon. the Baroness —,' 'The Right Hon. Lady —,' or 'The Lady —.' Begin: 'My Lady.' Refer to as 'Your Ladyship.'

Baronet—'Sir' [Christian name and surname], Bart.' Commence: 'Sir.'

Baronet's Wife—'Lady' [surname]. Begin: 'Madam.' Refer to as 'Your Ladyship.'

Bishop, Colonial—As Scottish bishop.

Bishop, English—'The Right Rev. the Lord Bishop of London,' or 'The Lord Bishop of London.' Begin: 'My Lord Bishop.' Refer to as 'Your Lordship.' In formal documents a Bishop is 'The Right Rev. Father in God, Arthur, by Divine permission Lord Bishop of London.'

Bishop, Irish, consecrated before 1868—As English bishop. *Bishop, Irish, consecrated since 1868*—'The Right Rev. the Bishop of Ossory,' or in case of the Bishops of Meath and Tuam, 'The Most Rev.' Begin: 'Right Rev. Sir,' or 'Most Rev. Sir.'

Bishop, Retired—'The Right Rev. Bishop —,' or 'The Right Rev. —, D.D.' Begin: 'Right Rev. Sir.'

Bishop, Scottish—'The Right Rev. the Bishop of St Andrews, Dunkeld, and Dunblane,' or 'The Right Rev. Bishop Plumb.' The Bishop who holds the position of Primus is generally addressed 'The Right

- Rev. the Primus' The use of 'Lord Bishop' and 'My Lord' is incorrect.
- Bishop, Suffragan*—The Right Rev. the Bishop Suffragan of Bedford. Begin: 'Right Rev. Sir.'
- Bishops' Wives and Children* have no titles.
- Clergy*—The Rev. [Christian name and surname]. Begin: 'Rev. Sir.' If son of a Duke or Marquess, 'The Rev. Lord' [Christian name and surname]. If the son of an Earl, Viscount, or Baron, 'The Rev. the Hon.' [Christian name and surname] is beginning to supersede 'The Hon. and Rev.'
- Companion of an Order of Knighthood*—The initials, C.B., C.M.G., C.S.I., or C.I.E., as it may be, are subjoined to the ordinary form of address.
- Consul, British*—_____, Esq., H.B.M.'s Agent and Consul-General, 'Consul-General,' 'Consul,' or 'Vice-Consul,' as it may be.
- Countess*—The Right Hon. the Countess of _____. Begin: 'Madam.' Refer to as 'Your Ladyship.'
- Dean*—The Very Rev. the Dean of _____. Begin: 'Very Rev. Sir.'
- Doctor*—The initials D.D., M.D., LL.D., Mus.D., are placed after the ordinary form of address, as 'The Rev. James Macgregor, D.D.,' 'Thomas Keith, Esq., M.D.' But 'The Rev. Dr Macgregor,' 'Dr Thomas Keith,' are also frequently used.
- Dowager*—On the marriage of a peer or Baronet, the widow of the previous holder of the title becomes 'Dowager,' and is addressed 'The Right Hon. the Dowager Countess of ____,' 'The Dowager Lady ____.' As more than one Dowager may hold the same title, the term is less used than formerly, and the Christian name is instead coming to be employed as a distinction—e.g. 'The Right Hon. Helen Countess of ____.'
- Duchess*—Her Grace the Duchess of _____. Begin: 'Madam.' Refer to as 'Your Grace.'
- Duke*—His Grace the Duke of _____. Begin: 'My Lord Duke.' Refer to as 'Your Grace.'
- Duke's Daughter*—The Right Hon. Lady [Christian name and surname], or 'The Lady' [Christian name and surname], the surname being that of her husband if married. Begin: 'Madam.' Refer to as 'Your Ladyship.' If married to a peer, she is addressed according to her husband's rank only. This, however, does not hold in the case of peers by courtesy, and a Duke's daughter married to the eldest son of an Earl, after the prefix 'Lady,' sometimes takes her own Christian name, followed by her husband's courtesy title.
- Duke's Eldest Son and his Children*—The courtesy title is treated as if it were an actual peerage; his eldest son taking the grandfather's third title, and being addressed as if a peer.
- Duke's Eldest Son's Wife*—As if her husband's courtesy title were an actual peerage.
- Duke's Younger Son*—The Right Hon. Lord [Christian name and surname], or 'The Lord' [Christian name and surname]. Begin: 'My Lord.' Refer to as 'Your Lordship.'
- Duke's Younger Son's Wife*—The Right Hon. Lady, or 'The Lady' [husband's Christian name and surname]. Begin: 'Madam.' Refer to as 'Your Ladyship.'
- Earl*—The Right Hon. the Earl of _____. Begin: 'My Lord.' Refer to as 'Your Lordship.'
- Earl's Daughter*—As Duke's daughter.
- Earl's Eldest Son, and Earl's Eldest Son's Wife*—As if the courtesy title were an actual peerage.
- Earl's Younger Son and his Wife*—As Baron's son and his wife.
- Governor of Colony*—His Excellency [ordinary designation], Governor of _____. Begin according to rank, and refer to as 'Your Excellency.'
- Judge, English or Irish*—The Hon. Sir _____, if a Knight, or 'The Hon. Mr Justice _____,' Begin: 'Sir.' On the bench only he is addressed as 'My Lord,' and referred to as 'Your Lordship.'
- Judge of County Court*—His Honour Judge _____. When on the bench, referred to as 'Your Honour.'
- Judges, Scottish*—See *Lord of Session*.
- Justice of Peace in England* (not Scotland) by custom referred to when on the bench as 'Your Worship.' (He is not 'Right Worshipful'.)
- King*—The King's Most Excellent Majesty. Begin: 'Sire,' or 'May it please your Majesty,' or 'Lord _____ presents his duty to Your Majesty.' Refer to as 'Your Majesty.'
- King's Counsel*—append K.C. to ordinary address.
- Knight Bachelor*—As Baronet, except that the word 'Bart.' is omitted.
- Knight of the Bath, of St Michael and St George, or of the Star of India*—Sir [Christian name and surname], with the initials G.C.B., K.C.B., K.M.G., or K.S.I., added. Begin: 'Sir.'
- Knight of the Garter, of the Thistle, or of St Patrick*—The initials, K.G., K.T., or K.P., as it may be, are to be added to the address.
- Knight's Wife, whether wife of Knight Bachelor, of the Bath, of St Michael and St George, or of the Star of India*—As Baronet's wife.
- Lord Advocate of Scotland*—The Right Hon. the Lord Advocate. Usual beginning: 'My Lord,' though 'Sir' is said to be more correct.
- Lord Chancellor*—The Right Hon. the Lord High Chancellor. Begin and refer to according to rank.
- Lord Chief-Justice*—The Right Hon. the Lord Chief-Justice of England, or 'The Right Hon. Sir _____,' Lord Chief-Justice of England. Begin, if a peer, according to his degree, otherwise as under *Judge*.
- Lord High Commissioner to the General Assembly*—His Grace the Lord High Commissioner. Begin according to rank as a peer. Refer to as 'Your Grace.'
- Lord Justice-Clerk*—The Right Hon. the Lord Justice-Clerk. Begin: 'My Lord.' Refer to as 'Your Lordship.'
- Lord Justice-General of Scotland*—The Right Hon. the Lord Justice-General. Begin: 'My Lord.' Refer to as 'Your Lordship.'
- Lord Justice of Appeal*—The Right Hon. the Lord Justice _____, or 'The Right Hon. Sir _____.' Begin and refer to as a Judge.
- Lord Mayor of London, York, Dublin, &c.*—The Right Hon. the Lord Mayor of London, or 'The Right Hon. _____,' Lord Mayor of London. Begin: 'My Lord.' Refer to as 'Your Lordship.'
- Lord Mayor's Wife*—The Right Hon. the Lady Mayoress of _____. Begin: 'Madam.' Refer to as 'Your Ladyship.'
- Lord of Appeal in Ordinary, and his Wife*—As Baron and Baroness. Their children have no title.
- Lord of Session in Scotland*—The Hon. Lord _____. Begin: 'My Lord.' Till 1905 without any title, their wives have now the style of 'Lady.'
- Lord Provost*—The Right Hon. the Lord Provost of Edinburgh, 'The Right Hon. the Lord Provost of Glasgow,' 'The Lord Provost of Aberdeen' or of 'Perth.' Begin: 'My Lord Provost,' or 'My Lord.' Refer to as 'Your Lordship.' The Lord Provost's wife has no title.
- Maid of Honour*—The Hon. Miss _____. Begin: 'Madam.'
- Marchioness*—The Most Hon. the Marchioness of _____. Begin: 'Madam.' Refer to as 'Your Ladyship.'
- Marquess*—The Most Hon. the Marquess of _____. Begin: 'My Lord Marquess.' Refer to as 'Your Lordship.'
- Marquess's Daughter*—Like Duke's daughter.
- Marquess's Eldest Son*—Like Duke's eldest son.
- Marquess's Younger Son*—Like Duke's younger son.
- Mayor of a City*—The Right Worshipful [The Worshipful, if of a borough] the Mayor of _____. Address: 'Sir.' Refer to as 'Your Worship.'
- Member of Parliament*—Add M.P. to ordinary address.
- Minister Resident*—_____, Esq. [or according to rank], H.B.M.'s Minister Resident, _____. Begin: 'Sir.'
- Moderator of the Established Church of Scotland*—The Right Reverend the Moderator of _____. Begin: 'Right Rev. Sir.'
- Officers in the Army and Navy*—The professional is prefixed to any other rank—e.g. 'Admiral the Right Hon. the Earl of _____,' 'Lieut.-Col. Sir _____,' K.C.B. Officers below the rank of Captain in the Army or Commander in the Navy are more generally addressed by their social, not professional rank, followed by the name of the regiment, R.A., R.E., or R.N., as may be.
- Premier*—According to his rank.
- Prince*—If a Duke, 'His Royal Highness the Duke of _____,' If not a Duke, 'His Royal Highness Prince' [Christian name]. Begin, in either case, 'Sir.' Refer to as 'Your Royal Highness.'
- Princess*—If a Duchess, 'Her Royal Highness the Duchess of _____,' If not a Duchess, 'Her Royal

Highness the Princess' [Christian name]. Begin: 'Madam.' Refer to as 'Your Royal Highness.'

Principal of a Scottish University—When a clergyman, 'The Very Rev. the Principal of —,' or 'The Very Rev. Principal' [surname].

Privy Councillor—'The Right Hon.' followed by name or title. Begin and refer to according to rank.

QUEEN—'The Queen's Most Excellent Majesty.' Begin: 'Madam,' or 'May it please Your Majesty.' Otherwise, 'Lord — presents his duty to Your Majesty.' Refer to as 'Your Majesty.'

Secretary of State—'His Majesty's Principal Secretary of State for the — Department.'

Serjeant-at-Law—'Serjeant —,' or 'Mr Serjeant —.'

Sheriff of London—'The Right Worshipful.'

Vice-Chancellor—As a Judge. Begin: 'Sir.' Address on the Bench as 'My Lord.'

Governor of India—As Governor of Colony, *mutatis mutandis*.

Viscount—'The Right Hon. the Lord Viscount —,' or 'The Lord Viscount —.' Begin: 'My Lord.' Refer to as 'Your Lordship.'

Viscountess—'The Right Hon. the Viscountess —,' or 'The Viscountess —.' Begin: 'Madam.' Refer to as 'Your Ladyship.'

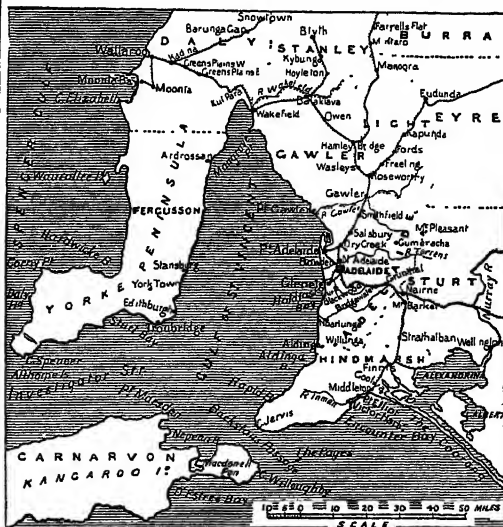

Viscount's Daughter, Son, and Son's Wife—As Baron's daughter, son, and son's wife.

In correspondence with equals or personal friends letters are begun less formally—e.g., 'My dear Lord,' 'Dear Lord —,' 'Dear Sir James.' We are less ceremonious than our ancestors a few generations ago, when letters to the nearest relatives and most intimate friends were begun and ended in the most formal manner. Designations like 'Mrs General —,' 'Mrs Captain —,' 'Mrs Dr —,' which were fifty years ago not uncommon, were always improper. Persons holding offices other than those enumerated are addressed in the usual form, 'Sir,' 'Dear Sir,' or 'My dear Sir,' according to the more or less formal terms on which the writer may be with his correspondent. A firm is addressed 'Gentlemen,' or 'Dear Sirs.'

Adelaer (Norwegian, 'Eagle'), a name of honour given to Curt Sivertsen (1622-75), born at Brevig, in Norway, who greatly distinguished himself in the naval service of Venice against the Turks. He died just after taking command of the Danish fleet for an expedition against Sweden. Frederick III. made him admiral of the Danish fleet, ennobled him, and gave him the name of Adelaer.

Adelaide, capital of South Australia, is situated on the Torrens, an insignificant stream running into St Vincent Gulf. It stands on a large plain which is walled in on the eastern and southern sides by the Mount Lofty range. The first settlement was made in 1836, and named after the queen of William IV. The Torrens separates the town proper (which is enclosed in a belt of park lands) from the residential suburb of North Adelaide; a dam retains in the river-bed at this point enough water for regatta purposes, and four bridges span the long, narrow lake thus formed. The streets are broad and regularly laid out, cross each other at right angles, and are for the most part planted with trees. Among the public buildings are the parliament houses; government offices, post-office, and town-hall; South Australian Institute, with museum, library, and art-galleries; and hospital. The botanical garden, with the botanical garden park, covers more than 120 acres of ground. Adelaide is abundantly supplied with water from reservoirs several miles distant. The chief manufactures are woollen, leather, iron, and earthenware goods; but the prosperity of the city depends on its being the great emporium for South Australia. Wheat and wool account for more than half the export figures; copper ore is also exported, and there is a growing trade in wine. Among educational institutions the most important are the Adelaide University; St Barnabas Theological College, opened in 1881;

and two fine public schools, St Peter's College (Anglican) and Prince Alfred College (Wesleyan). Adelaide is the seat of an Anglican and of a Roman Catholic bishop. It is the terminus of the direct telegraph-line to London, *via* Port Darwin; it is connected by rail with Broken Hill and Melbourne (and so with Sydney and Brisbane), by the transcontinental railway with Kalgoorlie and Perth, while the Australian government is constructing another transcontinental line which will give com-

munication with Port Darwin to the north. The city's port is at Port Adelaide, on the tidal portion of the Torrens; lower down at the river-mouth a new harbour for the great overseas mail-boats has been constructed. Glenelg on the Gulf, 5 miles away, is the principal watering-place. Adelaide is a great share-market for the gold-mines of Western Australia and the silver of Broken Hill. Port Adelaide ranks third amongst Australian ports. Pop. of Adelaide with suburbs inside a ten-mile radius (1901) 162,100; (1911) 189,982; (1921) 255,318.

Adelaide, QUEEN (1792-1849), daughter of the Duke of Saxe-Meiningen and consort of William IV. (q.v.) of England, whom (as Duke of Clarence) she married in 1818. She was much more worthy than popular. See *Memoir* by Doran (1861).

Adelboden, a Swiss winter-sport resort, 24 miles S. of Thun.

Adélie Land, a portion of Antarctica (q.v.), lying approximately in lat. 66° S. and between long. 135° and 140° E., was discovered by Dumont D'Urville in 1840.

Adelsberg (Slov. *Postojna*, Ital. *Postumia*), a town in Italian Carniola, 22 miles NE. of Trieste. Near it are many caves, the most famous being a large stalactite cavern, the *Adelsberg Grotto*. This cavern, the largest in Europe, is divided into the old and the new grotto, the latter discovered in 1816. The old grotto is 858 feet in length; the new, 8550 feet. The various chambers, called by names such as the Dome, the Dancing-hall, the Belvedere, contain stalactites and stalagmites of great size and grotesque forms. The river Poik runs through a part of the grotto, and then disappears below the ground. In its waters the *Proteus* (q.v.) is found.

Adelung, JOHANN CHRISTOPH, a distinguished linguist and lexicographer, was born 1732, in Pomerania, and died September 10, 1806, at Dresden,

where, since 1787, he had held the office of chief-librarian. His chief works are his *Wörterbuch der Hochdeutschen Mundart* (5 vols. 1774-86), in which he took Dr Johnson as his model; and his *Mithridates oder allgemeine Sprachenkunde* (1806), a work on general philology.

Ademption means that if a testator bequeaths a specific article, or specific property, and before his death the article or property is destroyed or ceases to be part of his estate, either by the act of the testator, or otherwise, then the legatee gets nothing. It is often a question of difficulty to say whether the bequest was really specific. In Roman law ademption did not occur unless it was shown that the testator intended to adeem the legacy. But both in England and in Scotland it is now settled that ademption operates, independently of the intention of the testator, wherever a specific subject is bequeathed and that subject does not remain as part of the testator's estate at the date of his death. A mere change in the name or form of the subject bequeathed does not involve ademption if, despite such change, the thing itself, or substantially the same thing, continues to be part of the testator's estate.

Aden, a peninsula and town on the SW. coast of Arabia, 105 miles E. of the strait of Bab-el-Mandeb, the entrance to the Red Sea. It is in 12° 47' N. lat., 45° 10' E. long., and is a British possession. The peninsula is a mass of volcanic rocks, 5 miles in length from E. to W., the highest point being 1776 feet in height. It is joined to the mainland by a narrow, level, and sandy isthmus. The town is on the eastern shore of the peninsula, stands in the crater of an extinct volcano, and is surrounded by indescribably barren, cinder-like rocks. The main crater is known as the Devil's Punch-bowl. Frequently the heat is intense; but the very dry hot climate, though depressing, is unusually healthy for the tropics. The Romans occupied it in the 1st century A.D. Up to the time of the circumnavigation of Africa, it was the chief mart of Asiatic produce for the Western nations. The Portuguese held it for a short time; but in 1838 it had sunk to be a village of 600 inhabitants. The increasing importance of the Red Sea route to India gave Aden great value as a station for England to hold. Maltreatment of shipwrecked mariners led to English interference and fruitless negotiations with the Arab sultan. In 1839, after a few hours' contest, Aden fell into the hands of the British. In its medieval prosperity, Aden had a magnificent system of cisterns for collecting rain-water. They had fallen into utter disrepair; but some of them have been restored so as to be serviceable. The present water-supply depends partly on the distillation of sea-water, and is also drawn from these cisterns, from an aqueduct, and from wells sunk to a depth of 120 to 190 feet in the solid rock: all water must be paid for.

Aden is of very great importance to Britain, both in a mercantile and naval point of view, especially as a great coaling-station; it has a garrison and strong fortifications. The population and resources of the place have rapidly increased since 1838, and the opening of the Suez Canal in 1869 gave it a great impetus. The exports include coffee, gums, spices, cotton, tobacco, grain, hides, sugar. A railway runs from Aden to Lahej and beyond. It is on the cable from Suez to Bombay and to the Cape, and has a wireless station. To provide for its growing population, a considerable territory on the mainland has been added to the peninsula (in all 75 sq. m.), besides a protectorate (1905) of 9000 sq. m.; the settlement, which includes Perim, and

is politically connected with Bombay (five days' sailing distant), had in 1921 a population of 54,923. The Kuria Muria islands are attached to Aden. The bulk of the natives of Aden are Arabs and Somalis from Africa, all speaking Arabic. In the settlement there are besides Aden proper, called the Camp, or the Crater (whose population cannot for military reasons be allowed to increase much), two other centres of population—Steamer Point, which is cooler than the Crater; and the outlying town of Shaikh Othman, 10 miles towards the interior.

Adenitis (Gr. *adēn*, 'a gland') and **LYMPHANGITIS** (Gr. *angeion*, 'a vessel') are the terms employed in medicine to indicate inflammation of the lymphatic glands and inflammation of the lymphatic vessels respectively. In most instances of inflammation in the absorbent or lymphatic system the vessels and glands are simultaneously involved. Although there is plenty of evidence, from the examination of the dead body, that inflammation of the lymphatics may occur internally, it is only observed in the living subject in connection with the skin or an ulcerated surface, and is most common in the arm or leg, as these parts are most exposed to injury and irritation. The disease usually originates in an open wound of almost any form, as a puncture, a cut, or a blister. This wound is directly infected by some morbid matter, as, for example, the organisms present in decomposing mud or in the discharge from a septic sore. The inflammation that is thus set up in the lymphatics always extends towards the trunk, never in the opposite direction. The degree of inflammation of the gland may vary from slight enlargement, with tenderness on pressure, to profuse suppuration.

Adenoids are 'gland-like' growths (usually in children or young persons), soft, spongy tissue between the back of the nose and the throat, which impede the breathing, provoke asthma, give rise to a catarrh tending to produce deafness, induce a dull and vacant expression of countenance, and seriously hinder healthy bodily development. Like enlarged tonsils, adenoids may sometimes disappear as a child reaches adolescence; but in many cases surgical removal is the only remedy.

Adenoma means a tumour composed of tissue resembling a gland in structure. The prefix *adeno-* is used in medicine to indicate a glandular nature, as in the terms Adeno-sarcoma, Adeno-carcinoma.

Adenostoma, a Californian genus of rosaceous shrubs. *A. fasciculatum* forms the thickets called chaparral on dry grounds.

Aderbaijan, Aderbijan. See AZERBAIJAN.

Aderno (ancient *Adranum*), a town of Sicily, 17 miles NW. of Catania. It is situated at the base of Mount Etna, has an ancient Norman tower, now a prison, and several churches. Population, 30,000.

Adersbach Rocks, a remarkable labyrinthine group of sandstone rocks situated near the village of Adersbach, in the NE. of Bohemia. The aspect of some parts of the group has been compared to that of a city ruined by a conflagration. There are thousands of curious cones, peaks, and pinnacles (one over 200 feet high); many of which have names such as 'The Praying Monk,' and 'Sugarloaf.' The structure of the rocks has been produced, not by any commotion of the earth, but by the influences of rain, frost, and other atmospheric changes, wearing down the soft sandstone by very deep furrows into fantastic forms.

Adhesion, in Pathology, a vital union between two surfaces of a living body which have been either naturally or artificially separated. In the healing of Wounds (q.v.), it is usually an altogether

beneficial process; though even in this case it may cause deformity—e.g. when adjacent surfaces of two fingers are allowed to become united by adhesion after a burn. After injuries to joints, adhesion frequently takes place between the injured structures and those adjoining, which may cause subsequent stiffness. Adhesion is a frequent consequence of inflammation of serous and synovial membranes—e.g. Pleurisy (q.v.) may cause adhesion of the lung to the chest-wall; Inflammation (q.v.) of a bursa or sac may lead to its obliteration by adhesion of its opposing surfaces. In inflammation of mucous membranes it is rare.

Adhesion, in Physics. See COHESION.

Adiabene, a district of Assyria, E. of the Upper Tigris, between the greater and the lesser Zab rivers.

Adiantum. See MAIDENHAIR.

Adia'phora (Gr.), things indifferent which men might or might not do without violation of the law of God. The name was specially applied during the Protestant controversy in Germany to certain customs in use in the ritual of the Roman Church, which were declared things indifferent—of which the use was an open question—by the Leipzig interim of 1548. The most important of these were episcopal jurisdiction, and the use in religious worship of pictures, candles, suplices, Latin hymns and vespers. These Melancthon and his party were ready to accept for the sake of the harmony of the church, while more strenuous Lutherans saw in such conformity a renunciation of the faith.

Ad'igé (Ger. *Etsch*; ancient *Athēsis*), after the Po, the most important river in Italy, rises in the Rhetian Alps, and is formed by various streamlets which descend from these mountains and unite at Glurns. From Glurns it flows east into Tyrol, then, after a slight *détour* to the south-east, it flows due south past Trent and Roveredo into Lombardy, and, passing Verona, takes a south-eastern sweep, discharging its waters into the Adriatic, not far north of the Po. It is very rapid, and subject to sudden swellings and overflows, which cause great damage to the surrounding country. Its banks have repeatedly been the scenes of bloody engagements. Its length is about 250 miles; its breadth in the plain of Lombardy, 650 feet; its depth, from 10 to 16 feet. It is navigable as far as Trent, but the navigation is difficult, on account of the swiftness of the current. The Adige forms a joint delta with the Po. Within historic times it has changed its course considerably. Formerly it entered the Adriatic farther north than now.

Adi Granth, or GRANTH SAHIB, the sacred books of the Sikhs (q.v.).

Adipic Acid, $C_6H_8(COOH)_2$ (Lat. *adeps*, 'fat'), a member of the dicarboxylic acids, of which oxalic acid is the lowest member, is a white crystalline solid, melting at $148^\circ C$. It is obtained from fats by oxidation with nitric acid.

Adipoce're (Lat. *adeps*, 'fat,' and *cera*, 'wax'), a substance resembling a mixture of fat and wax, and resulting from the decomposition of animal bodies in moist places or under water. Human bodies have been found, on disinterment, reduced to this state. Lean beef kept under running water for three weeks was found reduced to a fatty substance. A piece of a liver that has suffered what is called fatty degeneration, if immersed for some time in water, is said to become exactly like adipocere.

Adipose Tissue consists of an aggregation of minute spherical pouches or vesicles filled with fat or oil. Under the microscope, each vesicle presents a very delicate envelope inclosing a drop of the oily matter. Thus it is that in the living

body the fat, although nearly liquid, is not moved by gravitation, as is the case when the filamentous tissues are infiltrated by the water of dropsy. It is copiously supplied with capillary blood-vessels, but no nerves have been seen to end in it, and thus it may be punctured without causing pain. Adipose tissue is widely distributed throughout the body. It occurs as the yellow marrow of bones. A considerable layer is found under the skin, where it serves to give smoothness and roundness to the contour, and, being a bad conductor of heat, it is specially valuable in retaining the warmth of the bodies of animals exposed to great cold, such as whales. Being light and elastic, it forms an excellent packing substance; hence it is found surrounding large vessels and nerves, in the omentum and mesentery, round the kidneys, joints, &c., where it affords support, and protects from injurious pressure. Its utilisation as a reserve supply of nutriment is well illustrated in hibernating animals like the hedgehog.

Fat Cells (highly magnified):

m, membranous envelope; *n*, nucleus of cell; *fg*, fat globule; *ct*, connective tissue. Blood-vessels not represented.

body the fat, although nearly liquid, is not moved by gravitation, as is the case when the filamentous tissues are infiltrated by the water of dropsy. It is copiously supplied with capillary blood-vessels, but no nerves have been seen to end in it, and thus it may be punctured without causing pain. Adipose tissue is widely distributed throughout the body. It occurs as the yellow marrow of bones. A considerable layer is found under the skin, where it serves to give smoothness and roundness to the contour, and, being a bad conductor of heat, it is specially valuable in retaining the warmth of the bodies of animals exposed to great cold, such as whales. Being light and elastic, it forms an excellent packing substance; hence it is found surrounding large vessels and nerves, in the omentum and mesentery, round the kidneys, joints, &c., where it affords support, and protects from injurious pressure. Its utilisation as a reserve supply of nutriment is well illustrated in hibernating animals like the hedgehog.

Adirondack Mountains, the chief range in New York State, lie between Lakes Champlain and Ontario, and extend from the NE. corner of the state towards its centre. Rising from an elevated plateau about 2000 feet above sea-level, they are remarkable for grand and picturesque scenery; the highest summit, Mount Marcy, is 5402 feet high. Small lakes are numerous; the head-streams of the Hudson are here; and there is much fine timber in the region. The discovery of magnetic iron in the township of Macomb, led to the establishment of the village of Adirondack, but the works were afterwards abandoned. The whole northern wilderness of New York State is popularly known as the Adirondacks, and is a very favourite resort of sportsmen and pleasure-seekers.

Adjudication, in English law, means an order of the Bankruptcy Court, adjudging the debtor to be a bankrupt, and transferring his property to a trustee. See BANKRUPTCY. Another meaning of the term common both to English and Scottish law is the assessment by the Commissioners of Inland Revenue of the amount of stamp duty chargeable upon a document. The decision is indicated by an 'adjudication' stamp. In Scots law the word is used to denote a proceeding in court to take the heritable property of a debtor in satisfaction of debt, or to make up a title to heritable property where an agreement has been made to transfer it, and also in certain cases of intestacy.

In the United States, adjudication is used generally as the act or process of trying and determining judicially; it is the judgment of a court. Adjudication is also used specifically as the act of a court declaring a person bankrupt.

Adjustment of Average is a term used mainly in Marine Insurance, but also in Fire Insurance, to denote the ascertainment of the amount which the insured is entitled to receive under the policy, and of the proportion of the loss to be borne by each underwriter. For the principles on which this adjustment takes place, see INSURANCE (Marine and Fire). It is generally done by the brokers or the agents of the assured, or the matter may be referred to arbitration. The nature and amount of

damage being ascertained, an indorsement is made on the back of the policy, declaring the proportion of loss falling on each underwriter; and on this indorsement being signed or initialled by the latter, the loss is said to have been adjusted. Unless made under a serious mistake as to facts, this signature or initialling binds the underwriter both in a question with the insured and with the other underwriters. Adjustment of *General Average* is made as soon as the ship arrives at its destination, and in case of dispute is referred to a body of 'average adjusters.' See *AVERAGE*.

In the United States the adjustment, to be binding, must be intended by the parties to be absolute and final. No specific form is necessary; it may be made by indorsement on the policy, by payment of the loss, or the acceptance of an abandonment. Fraud on the part of either party will vitiate an adjustment. If one party is led into a mistake of fact by the fault of the other party, the adjustment will not bind him.

Adjutant, an officer not above the rank of major, appointed to assist the officer commanding a regiment of cavalry, a brigade of artillery, a battalion of infantry or of mounted infantry, or a depot of Royal Engineers, of infantry, or of Army Service Corps. In the field he acts as aide-de-camp, and in quarters has charge of correspondence, drill, and discipline; keeps and regulates the officers' duty roster (or list); issues orders by the commanding officer's authority; supervises the training of recruits and instructs the non-commissioned officers and newly joined officers; has charge of the orderly-room (colonel's office), and all records and returns prepared there; and is generally responsible to the commanding officer for the efficiency of the corps. An assistant-adjutant is sometimes appointed, a young officer in training for the post of adjutant. The appointment is held for three years, and may be extended. Adjutants must have a musketry-course certificate. They receive extra pay according to circumstances.—*Adjutants of Territorial Forces* are officers of the regular army appointed by the Army Council for a term of three years. The adjutant of a brigade is the Brigade-major (q.v.).—The *Adjutant-general* is the second military member of the Army Council. He deals with supply of officers and men, recruiting, pay, discipline, rewards, peace regulations, mobilisation, medical services, army schools, auxiliary forces. He is the head of an important department of the general staff, which ramifies through the larger units of the army. In those called infantry divisions and cavalry divisions there are assistant-adjutant-generals, deputy-assistant-adjutant-generals, one of each to each division. These are officers of the general staff, and all are, in their respective units, representatives of the adjutant-general, and have duties analogous to his.

In the French army an 'adjutant,' usually called *adjutant sous-officier*, corresponds in some degree to our sergeant-major. The *capitaine adjutant-major* corresponds to our adjutant.

Adjutant (*Leptoptilus argala*), a stork-like bird, common during summer in India. It is especially frequent in the north, and extends southwards to the Malay peninsula. Generally stork-like in appearance, it stands about 5 feet high, and measures 14 or 15 feet from tip to tip of extended wings. The four-sided pointed bill is very large; the head and neck are almost bare; and a sausage-like pouch, sometimes 16 inches long, and apparently connected with respiration, hangs down from the base of the neck. While feeding largely on carcasses and offal about the towns, it also fishes for living food, and sometimes devours birds and small mammals. According to popular superstition in

India, the brain of the living bird contains a stone valuable as a poison antidote. The loose under-tail

Adjutant.

feathers of this and of another species (the Marabout stork) are used for decorative purposes.

Adjygarh. See *AJAIGARH*.

Adler, NATHAN MARCUS, chief-rabbi, was born at Hanover in 1803, and educated at Gottingen, Erlangen, and Wurzburg. He became chief-rabbi of Oldenburg in 1829, of Hanover in 1830, and of the united congregations of Britain in 1845. His writings are *Sermons on the Jewish Faith*, and *Nethina Lager*, on the Targum of Onkelos. He died 21st January 1890.—HERMANN, his son, born in Hanover in 1839, graduated B.A. at London in 1859, and Ph.D. at Leipzig two years later. In 1863 he became Principal of the Jews' College in London, and in 1879, as delegate chief-rabbi, coadjutor to his father. He greatly distinguished himself by his learned and spirited defence of his co-religionists in the columns of the *Nineteenth Century* and elsewhere, especially by his vigorous controversy with Professor Goldwin Smith on the subject of the Jews as citizens. Hardly less able were his earlier reply to Colenso's criticism on the Pentateuch, and that to Max Müller, entitled *Is Judaism a Missionary Faith?* A member of the Mansion House Committee for the relief of the Jewish victims of persecution in Russia in 1881–82, Adler visited the conference of leading Jews at Berlin, and afterwards the colonies of Russian refugees in the Holy Land. Other works are *The Jews in England*; *Ibn Gabirol, the Poet Philosopher*, &c. He died 18th July 1911.

Ad Libitum (Latin, 'at pleasure'; in Italian, *a piacere*, or *a piacimento*) is a musical term which implies that the part so marked may be performed according to the taste of the principal performer, and not necessarily in strict time. *Ad Libitum* also frequently means that a part for a particular instrument or instruments, in instrumental scores or pianoforte arrangements, may either be played or entirely left out.

Admetus, the husband of Alcestis (q.v.).

Administration, in politics, is equivalent to the executive government of a state; in Britain, more especially the ministry.

Administration, *RIGHT OF*, is the right reserved by the law of Scotland to the husband of managing the wife's property. It is distinct from the *jus mariti* which before 1881 transferred the wife's movable estate to the husband. The wife

can now dispose of her income without her husband's consent, but not the capital.

Administrator, in the law of England, is the person to whom the Probate Division of the High Court commits the administration or distribution of the personal estate of a person dying intestate, or leaving a will in which no executor is named. The administrator is usually the wife or child or a creditor of the deceased, or a person who has an interest in the property. The Public Trustee may now be appointed administrator. The duties of an administrator are to pay the funeral expenses, the cost of obtaining probate of the will or 'letters of administration,' and the debts of the deceased, and thereafter to hand over the property to those entitled. In the Scottish law a father is **ADMINISTRATOR-IN-LAW** for his children, and, as such, is their guardian during minority.

In the United States an administrator is a person appointed by competent authority to manage and distribute the estate of an intestate. Any person competent to make contracts may be appointed. The husband of a deceased wife, or the wife of a deceased husband, the next of kin, or creditors of the decedent, may be appointed to administer upon the estate. An administrator is generally obliged to give a bond for the faithful performance of the duties therein mentioned.

Admiral, since the 13th century, the title borne by officers appointed to the command of a fleet or squadron. The word is said to be derived from the Arabic *Amir* or *Emir*, a man in authority; thus *Amir-al-Bahr*, commander of the sea, whence the abbreviation 'Amiral' or 'Admiral.' The first record of the use of the title in England is to be found in a convention signed at Bruges on 8th March 1297, in which Sir William Leybourne is styled 'Admiral of the Sea of the King of England.' In the 14th century we find the title conferred on the officers commanding the fleets for the protection of the coasts, and it was at this period also that the rank of Vice-admiral and Rear-admiral is first met with. In the early part of the 15th century we find mention made of an 'Admiral of England,' in the person of the Earl of Somerset, to whom extensive powers were granted; his successors in this office bore the title of 'Lord High Admiral,' who, in addition to exercising executive and administrative control, went afloat in command of the fleet when occasion required, as Lord Howard of Effingham did against the Spanish Armada and the Duke of York (afterwards James II.) against the Dutch. See **ADMIRALTY AND ADMIRALTY COURTS**.

By the middle of the 17th century our fleets had come to be divided into three squadrons, distinguished as the Red or Centre, commanded by the admiral; the White or Van, commanded by the vice-admiral; and the Rear or Blue, commanded by the rear-admiral, each having a distinctive ensign, red, white, or blue, as the case might be. From this followed the division of officers of flag-rank into Admirals, Vice-admirals, and Rear-admirals of the Red, White, and Blue respectively, the Red taking the senior place and the Blue the junior. As, however, in the 17th and 18th centuries the admiral commanding the Centre was in command not only of the Red squadron, but of the whole fleet, he flew the Union-jack at the main as 'Admiral of the Fleet'—hence that rank; and there were no Admirals of the Red until after the battle of Trafalgar, when, as a special compliment to the navy, this rank was instituted. The flag of Admirals of the Red was plain red; of Admirals of the White, white with a red St George's Cross; of Admirals of the Blue, plain blue. The ships of different divisions of the fleet flew ensigns of the same colour as the flag of the admiral under whom they were serving. In 1863 these distinctions were done away with, the white

flag with the red St George's Cross being definitely selected as the flag for admirals, with the corresponding white ensign as the ensign for H.M. ships. Admirals, vice-admirals, and rear-admirals fly their flags at the main, fore, and mizen respectively; but as battleships and large cruisers have mostly only one mast, a vice-admiral's flag is distinguished by a red ball in the inner upper canton of the flag, and that of a rear-admiral by two balls.

Flag-officers, as officers of flag-rank are termed, rise from captain to full admiral by seniority, but promotion to 'Admiral of the Fleet' is by selection with the approval of the sovereign. The establishment of flag-officers after the Great War (1919) was: admirals of the fleet, 6; admirals, 12; vice-admirals, 23; rear-admirals, 62.

In the navy of the United States no officer of higher rank than captain was commissioned prior to 1862 (with one single exception). In that year there were authorised to be commissioned 9 rear-admirals on the active list, and 9 on the retired or reserve list. Subsequently the number on the active list was reduced to 7, the number on the retired list varying from time to time. Rear-admirals have the relative rank of major-generals. The rank of vice-admiral and that of admiral were created in 1864 and 1866; both had lapsed in 1891, but in 1899 Admiral Dewey was appointed to the highest rank.

Admiralty, **BOARD OF**, a government department which has the management of all matters concerning the British navy. It comprises nine lords commissioners, who decide collectively on important questions. Besides this collective or corporate action, each has special duties assigned to him. There are three civil or political lords, and six naval or sea lords. The First Lord, who is always a cabinet minister, besides having a general control, is responsible for all business of the Admiralty, and the other members of the Board act as his assistants in the various duties which are divided among them. Thus the First Naval Lord is responsible to the First Lord for the administration of such business as the movements and condition of the fleet operations and general naval policy, and is chief of the naval staff. He also advises as to appointments of flag-officers and certain officers in command of ships. The Second Naval Lord assists the First Naval Lord, and is responsible for all matters in connection with *personnel*. The Fourth Naval Lord assists the First Naval Lord, and appoints officers of civil branches, looks after fuelling, victualling, and legal matters, &c., connected with the fleet. The Controller of the Navy is responsible to the First Lord for business relating to the *matériel* of the fleet—that is, the building and repairing of ships—and to guns and naval stores. The Civil Lord acts as assistant to the Parliamentary Secretary. Under the lords are the First Secretary (parliamentary), the Second Secretary (permanent), and the Naval Secretary (professional). The Parliamentary and Financial Secretary is responsible to the First Lord for the finance of the department and parliamentary duties. The Permanent Secretary has exclusive charge of the secretariate, under direction of the First Lord, and is responsible for the discipline and general organisation of admiralty office. The post of private secretary to the First Lord is an appointment usually held by a post-captain of the Royal Navy. The only lord who necessarily resigns when the prime minister resigns is the First Lord, yet a change of the others frequently takes place. The other two naval lords are called Deputy Chief of Staff and Assistant Chief of Staff—the former advises on war operations in home waters; the latter advises on war operations abroad and on anti-submarine matters. There is also a liaison officer of high rank to advise as to matters in connection with the Royal

Air Force. All delicate or doubtful matters are specially reserved for the First Lord; but in the Board meetings he has only one vote, like the rest, though, from his general parliamentary responsibility, he practically has both an absolute veto and an absolute power of giving action to his views.

Admiralty Courts. The Admiralty Court (whose functions are now exercised by the Probate, Divorce and Admiralty Division of the High Court of Justice, constituted in 1873-5) was created to try and decide maritime causes. Formerly, the maritime courts of England were divided into the *Instance Court* and the *Prize Court*—separate tribunals, though usually presided over by the same judge; the Prize Court (q.v.) exists only during time of war. The jurisdiction in question of booty of war, and the distribution thereof, was in 1865 conferred on the Admiralty Court; and jurisdiction relating to the attack and capture of pirates is vested in the court in this country, and in the vice-admiralty courts in the colonies and foreign possessions. The proceedings of the Admiralty Court, like those in the ecclesiastical courts, were originally based on the civil law, and upon this account it was usually held at Doctors Commons. But it is merely as the basis of the earlier mercantile codes, such as the Rhodian laws and those of Oleron, and by no means exclusively, that the civil law is of authority in these courts. Questions of the utmost nicety in the law of nations fall to be decided by maritime courts in time of war. The appeal from the Admiralty Court, which was originally to the king in Chancery, is now to the Court of Appeal created by the Judicature Act of 1873-5. Appeals from the vice-admiralty courts in British colonies and dependencies formerly lay to the Admiralty Court in England, but are now carried to the Court of Appeal. The civil jurisdiction of the Admiralty Courts now extends generally (and the county courts also exercise part of it) to disputes between part-owners of a ship, suits for mariners' and officers' wages, suits for pilotage, suits on bottomry and respondentia bonds, and relating to salvage, wreck, collision of ships, &c. County courts are expressly prohibited from entertaining questions of prize, questions arising under the act for the suppression of the slave-trade, or questions of Admiralty jurisdiction by way of appeal. In criminal matters, the Admiralty Court formerly took cognisance of piracy and other offences on the sea, or on the coasts beyond the limits of any county, and, concurrently with the common law courts, of certain felonies committed in the main stream of great rivers below the bridges. This criminal jurisdiction is regulated now by the Criminal Law Consolidation Acts generally; and the criminal jurisdiction of the Admiralty Court may be regarded as obsolete. There is a separate Court of Admiralty in Ireland. The Admiralty Court of Scotland has been abolished, and its ordinary jurisdiction transferred to the Court of Session, the Court of Justiciary, and the sheriffs; questions of prizes, captures, condemnations, and the like, being vested exclusively in the Admiralty Division of the High Court in England.

In the United States, the court of original Admiralty jurisdiction is the United States district court. From this court causes may be removed, in certain cases to the circuit, and ultimately to the supreme court. The jurisdiction of Admiralty has been extended beyond that of the English Admiralty Court. Its *civil* jurisdiction extends to cases of salvage, bonds of bottomry, respondentia, seamen's wages, seizures under the law of imposts, navigation or trade, cases of prize or ransom, charter-parties, contracts of affreightment between different states or foreign ports, contracts for conveyance of passengers, contracts with material men, jettisons,

maritime contributions and averages, pilotage, surveys of ship and cargo, and generally to all damages and trespasses occurring on the high seas. Its *criminal* jurisdiction extends to all crimes and offences committed on the high seas, or beyond the jurisdiction of any country. Courts of Admiralty, within the limits of their jurisdiction, resemble courts of equity in their practice and modes of proceeding, but are even more free from technical rules.

Admiralty Droits were formerly a portion of the hereditary revenues of the crown, arising from enemies' ships detained in the prospect of a declaration of war, or coming into port in ignorance of the commencement of hostilities, or from such ships as are taken by non-commissioned captors, the proceeds of wrecks, the goods of pirates, and the like. The proceeds of the Droits of Admiralty are now paid into the Exchequer for the public use.

Admiralty Island lies off the coast of Southern Alaska, in 57° 30' N. lat., and 134° 15' W. long. It is about 90 miles long, well wooded and watered; and contains coal and copper. It is inhabited, and belongs to the United States.

Admiralty Islands, a group of 40 islands, to the N.E. of New Guinea, about 2° S. lat., and 147° E. long. They were discovered by the Dutch in 1616. The largest is above 50 miles long, and is mountainous but fruitful; their total area is 878 sq. m. Some are volcanic, others are coral islands. They abound in coconut-trees, and are inhabited by a race of tawny frizzle-headed savages, of the Papuan stock, about 800 in number. Together with New Britain and some adjoining groups, they were annexed by Germany in 1885, and are now included in the Australian mandate for New Guinea.

Adobe (Span. *adobar*, 'to plaster') is a sun-dried brick. These unburnt bricks are commonly used, in Mexico, Texas, and Central America; and the houses built with them are very durable.

Adolphus, JOHN, born in London in 1768, was called to the bar in 1807, and became a successful Old Bailey practitioner. He died 16th July 1845. His historical and other works fill upwards of 20 volumes, the chief being a *History of the Reign of George III.* (1802; new ed. 1840-43).

Adonai, a Hebrew name for the Supreme Being; a plural form of *Adon*, 'lord' (see also ADONTS; and compare the art. JEHOVAH), combined with the pronoun of the first person. In reading the Scriptures aloud, the Jews pronounce 'Adonai' wherever the holy name JHVH is found in the text; and the name 'Jehovah' has arisen out of the consonants of *Jwh*, with the vowel points of *Adonai*.

Adoni, a town of the province of Madras, 64 miles N.E. of Bellary. Pop. (1891) 26,243; (1921) 30,232, many of them engaged in weaving.

Adonis, in Greek Mythology, a youth of marvellous beauty, beloved by Aphrodite. He was killed by a boar while hunting, and the goddess, coming too late to his rescue, changed his blood into flowers.—A yearly festival was celebrated in honour of Adonis, and consisted of two parts—a mourning for his departure to the under world, and a rejoicing for his return to Aphrodite. This festival, widely spread among the countries bordering on the Mediterranean, was celebrated with peculiar pomp at Byblus and Alexandria. Before the festival, wheat, fennel, and lettuce were sown in earthen and even in silver pots, and forced by heat; intended to indicate, doubtless, by their brief bloom, the transitoriness of earthly joy. The myths connected with Adonis belong originally to the East. They display a worship of the powers of nature conjoined with that of the heavenly bodies, and Adonis himself

appears to be the god of the solar year. The similarity of the name to the Phœnician *Adon*, which signified 'lord,' is unmistakable; and this name Adon was given to the king of heaven, the sun. See J. G. Frazer's *Attis, Adonis, Osiris* (1914).

Adonis, a herbaceous annual or perennial genus of Ranunculaceæ, of which only one, *Adonis autumnalis* (Pheasant's Eye), is a doubtful native of Britain. Its bright scarlet petals obtained for it the name of *Flos Adonis*, their colour having been ascribed to their being stained with the blood of Adonis. It is a well-known ornament of our gardens; in which also *Adonis vernalis* frequently appears, and *Adonis vernalis*, a perennial species common upon the lower hills of Middle and Southern Germany, with early and beautiful flowers.

Adoptianism, a heretical doctrine akin to Nestorianism, originated about the end of the 8th century in Spain. Elipandus, Archbishop of Toledo, and Felix, the Bishop of Urgel, advanced the opinion that Christ, in respect of his divine nature, was doubtless the Son of God; but that as to his human nature, he was only declared and adopted to be the first-born Son of God. The flame of controversy thus kindled, spread into the Frankish empire, and gave occasion to three synods, one held at Ratisbon (792), another at Frankfort (794), and a third at Aix-la-Chapelle (799). Adoptianism was condemned as heresy, and the Catholic doctrine of the unity of the two natures of Christ in one divine person was re-affirmed.

Adoption was a legal institution of much importance in both of the classical nations of antiquity, whose laws frequently encouraged the possession of a large family. Adoption, in the stricter sense, in the Roman law, applied only to the case in which a person in the power of his father or grandfather was transferred to that of the person adopting him. Where the person adopted was already emancipated from the paternal power (*patria potestas*), and was regarded by the law as his own master (*sui juris*), the proceeding was called adrogation (*adrogatio*). At Athens, the adopted child was transferred from his own family and parish or tribe (*demos*), into those of the adoptive father, whose property he inherited in the absence of legitimate children, and whose sacred rights he was bound to maintain. In fact, the theory of adoption at Athens, as in India, was that there might be some one to offer the funeral cake, and prevent a failure of the funeral ceremonies. Only Athenian citizens could be adopted, so that not only the next of kin, but the whole community were interested in preventing fraudulent adoptions. With this view, registration in the *demos* of the adoptive father was requisite, in order to entitle the son to the rights of citizenship as a member of it.

In Rome, the adopted child assumed the name, and became bound to discharge the religious duties, of the adoptive father, which usually consisted in sacrifices to the *penates* or other divinities. Adoption of a person who was *in potestate* was effected first by the form of a fictitious sale, and then under the authority of a magistrate, the prætor at Rome, or the governor (*præses*) in the provinces. Adrogation of a person who was *sui juris* originally required a vote of the people in the *Comitia Curiata*; but under the emperors it became the practice to effect it by an imperial rescript. This change of form made possible the adrogation of women. The entire property of the person adrogated passed to the adrogator. If a father, having children in his power, was adrogated, both he and his children passed into the power of the adrogator. Down to the time of Justinian the person adopted came

under the *patria potestas* of the adoptive father. The tie of agnatio with his former family ceased, and he became agnate to the members of the adoptive family. Under the legislation of Justinian adoption (except in special cases) no longer produced these effects. Adoption was unknown to the early law of the Teutonic nations; but in the 15th century it became a prominent feature in the codes and social life of Prussia and Austria, and other German states. There, and also in France, the ceremony was carried through in open court, and conferred indefeasible rights of succession. It is, however, in the Hindu law that adoption is chiefly, in modern times, an active institution. Adoption has never existed as an institution either in England or Scotland. The express adoption of a child—e.g. as the result of the advertisement which frequently appears—imposes no legal liability except under a contract with the true parent.

In the United States, adoption is regulated by the statutes of the several states. Generally, it is accomplished by mutual obligations, assumed in some form prescribed by law, binding upon the adopter to treat the one adopted as his own child, towards whom he will discharge all the duties of a parent; while the one adopted assumes all the obligations of a child towards a parent. But these laws differ in the several states, although they all aim at one result—viz. the creation of new civil relations of child and parent.

Adour, a French river, rising in the department of Hautes Pyrénées, and flowing 180 miles through Gers and Landes, till it enters the Atlantic below Bayonne. It is navigable for 80 miles.

Adowa, a town of Abyssinia, the capital of Tigré, stands 6270 feet above sea-level, and 145 miles NE. of Gondar. Adowa is the chief entrepôt of trade between the interior of Tigré and the coast. It has a great weekly market and an extensive transit trade, in which gold, ivory, and slaves are articles of importance. Pop. 4000. Near the town the Italians met with a disastrous defeat in 1896. See ABYSSINIA.

Adra, a Mediterranean seaport of Spain, in the province of Almería, 49 miles SE. of Granada. The Phœnician Abdeira (not the Thracian Abdera, q.v.) stood on a hill close by. There are lead-mines in the neighbourhood. Pop. 9000.

Adramyti (Turkish, *Edremit*), a town on the west coast of Asia Minor, opposite Mitylene, and amid rich olive-groves. Pop. 6000, much disturbed by migrations after the war of 1912-13. To the east lay the ancient *Adramyttum*.

Adrar, a region south of Morocco, extending from the coast some 600 miles into the Sahara, and containing oases. Adrar Suttuf is Spanish (see RIO DE ORO), Adrar Temur French.

Adrastus, a king of Argos, whose daughter married Polynices of Thebes, who had been exiled from his native city by his brother Eteocles. He led the expedition of the 'Seven against Thebes' to restore his son-in-law to his right, and was the only one that survived, as Amphiaræus had foretold. Ten years later he led the six sons of the heroes that had fallen to a new attack on Thebes—the war of the *Epigoni* ('descendants'). This attack was successful, but a son of Adrastus fell, and the father died of grief.

Adrenalin, a powerful syptic obtained from the Supra-renal Capsules (q.v.).

Adria, a town of northern Italy, in the province of Rovigo, between the Po and Adige, was founded by the Etruscans, and till the 12th century it was a flourishing harbour of the Adriatic, to which it gave name; but by the silting up of this coast

of Italy, it has been gradually separated from the sea, from which it is now 14 miles distant. It still retains several interesting remains of Etruscan and Roman antiquity, with a fine cathedral. Pop. 20,000.

Adrian, a city of Michigan, U.S., situated on the Raisin River. It is well furnished with water-power, commands the trade of a large grain-growing region, has several factories, and a Methodist college founded in 1859. The population is about 12,000.

Adrian, the name of six popes (see POPE), none of them very remarkable. Adrian IV. was by birth an Englishman, the only one that ever sat upon the papal chair. His name was Nicolas Breakspear. He was a native of Langley, near St Albans, became first a lay-brother or servant in the monastery of St Rufus, near Avignon, and in 1137 was elected its abbot. His zeal for strict discipline raised a combination to defame his character, and he had to appear before Eugenius III. at Rome. Here he not only cleared himself of all charges, but acquired the esteem of the pope, who appointed him cardinal-bishop of Albano in 1146. In 1154 he was raised to the papal see. It has been asserted that he granted Ireland to Henry II. Adrian was at first on friendly terms with the Emperor Frederick I.; but his high notions of the papal supremacy, as high even as Gregory VII.'s, led to the beginning of that long contest of the popes against the house of Hohenstaufen, which ended in the destruction of the dynasty. He was about to excommunicate Frederick, when he died at Anagni, 1159. See books on him by Taileton (1896), Mackie (1907), and Mann (1914).—For the Emperor Adrian, see HADRIAN.

Adrianople (Turkish *Edirne*; Bulgarian *Odrin*), a city of Thrace, stands on the navigable Maitza (the ancient *Hebrus*), 138 miles WNW. of Constantinople by rail. The city has upwards of 50,000 inhabitants, of whom about one-third are Turks. The splendid mosque of Selim II., the palace, and the immense bazaar of Ali Pasha may be named as its principal features. It has a silk-factory, and a considerable trade in opium, attar of roses, and wine. Founded or greatly improved by the Emperor Hadrian, Adrianople was the seat of the Ottoman sultanate from 1366 to 1453. The Russo-Turkish war was ended in 1829 by the Peace of Adrianople. After the capture of the Turkish army defending the Shipka Pass in 1878, the Russians entered unopposed. Taken after five months' siege by the Bulgarians in 1913, it was reoccupied by the Turks in the same year.

Adriatic Sea, a large arm of the Mediterranean Sea, extending 450 miles north-westward between the east coast of Italy and the west coast of the Balkan peninsula, being terminated to the south by the Strait of Otranto, 45 miles wide. In the north, it forms the Gulf of Venice, and in the north-east, the Gulf of Trieste. The west coast is comparatively low and has few inlets, and the north is marshy and edged with lagoons. On the other side, the coasts of Illyria, Croatia, Dalmatia, and Albania are steep, rocky, and barren, with many inlets, and begirt with a chain of almost innumerable small rocky islands. The total area of the sea, including islands, is calculated at 52,220 sq. m.—the area of the islands being 1290; the mean depth is 110 fathoms, the greatest depth 565 fathoms. The most considerable rivers flowing into the sea are the Adige and the Po, which are continually depositing soil on the coast, so that places once on the shore are now inland. The extreme saltiness of the Adriatic is probably owing to the comparatively small quantity of fresh water poured into it by rivers.

Navigation on the Adriatic is safe and pleasant in summer, but in winter the north-east gales (*bora*) are formidable, on account of the rocky and dangerous coasts on the east. Venice, Trieste, Fiume, Ancona, Bari, Brindisi are the chief ports. Tides are scarcely perceptible. The fisheries of the Adriatic are rich, and industriously worked. The sea owes its name to Adria (q.v.). See also ALBANIA, BUCENTAURO, DALMATIA, ITALY, &c.

Adule, or ADULIS, an ancient town of Ethiopia, on the Red Sea, or what is now Annesley Bay. It afterwards had some importance as the port of Axum. On its site is the modern village of Zulla. Here was found in the 6th century the *Monumentum Adulitanum*, a Greek inscription of the conquests of Ptolemy II. Euergetes.

Adullamites. The attempt to extend the franchise made in 1866 by the government of Earl Russell and Mr Gladstone, led many of the Whigs to secede from the Liberal leaders, and vote with the Conservatives. The designation of *Adullamites* was fastened on the new party, in consequence of Mr Bright having likened them to the political outlaws who took refuge with David in the cave of Adullam (1 Sam. xxii.).

Adulteration. The crime of food adulteration is a very old one. Pliny tells us of one article which was so extensively adulterated in his time, that even the wealthier members of the community could not obtain it in a state of purity. In England during the 11th century, drugs, as well as several different articles of food, were subjected to various processes of sophistication. In those early days, the means of detection of adulteration were, as may be imagined, neither so refined nor certain as those which we now possess, and in consequence—notwithstanding the greater punishments which were then enforced—the practice not only became very common, but it was carried out in a most unblushing fashion. In 1843 Mr Phillips, of the Inland Revenue, stated that it was supposed that there were no less than eight manufactories for the purpose of re-drying exhausted tea-leaves in London alone. People were employed to go about and buy up used tea-leaves at hotels, coffee-houses, and the like, which they did at the rate of twopenny half-penny a pound. The leaves gathered in this way were then taken to the manufactories, where they were immersed in a solution of gum, and dried. If the leaves, thus manufactured so far, were intended to be sold as ordinary black tea, they were finished by being mixed with rose-pink and black-lead. But not only was exhausted tea made use of; such things as the leaves of the sycamore, horse-chestnut, and sloe were freely employed, and these not alone, but in conjunction with catechu, green vitriol, and indigo. In a notice of Accum's book on food adulteration, published in 1820, the following passage occurs: 'Devoted to disease by baker, butcher, grocer, wine-merchant, spirit-dealer, cheesemonger, pastry-cook, and confectioner, we call in the physician to our assistance. But here again the pernicious system of fraud, as it has given the blow, steps in to defeat the remedy. The unprincipled dealer in drugs and medicines exerts the most potent and diabolical ingenuity in sophisticating the most potent and necessary drugs—Peruvian bark, rhubarb, ipecacuanha, magnesia, calomel, castor-oil, spirits of hartshorn, and almost every other medical commodity in general demand, and chemical preparation used in pharmacy.'

A century of general advancement has no doubt produced a great change in the purity of our food; but the quarterly reports of the public analysts continually remind us that we have not

yet finally banished the demon of food adulteration from our midst. The excuses which have at different times been urged in extenuation of adulteration are numerous, and in some cases even plausible. Thus we are told again and again that many articles of food are prepared and sold in an adulterated form in obedience to the public taste. Preserved vegetables must, it is said, possess a bright, permanent green hue, in order to be appreciated by the public. Peas do not retain their natural colour when preserved, and therefore the manufacturers of these articles colour them with verdigris or some similar salt of copper. Sauces and preserved meats must, it is alleged, be made, for similar reasons, to assume a red tint; butter and cheese must be yellow, and bread white; while confections must needs possess all the colours of the rainbow. Again, it is asserted that some forms of adulteration, or, as it is more euphoniously put, admixture, are quite allowable, seeing that they are undoubted improvements. Thus, it is maintained that to mix chicory with coffee is not only perfectly allowable, but commendable, seeing that the compound is by many considered to be superior to the pure coffee. So with the admixture of such things as flour and turmeric with mustard. As a third form of excuse, we have it openly asserted that certain things must be mixed with others in order to insure their preservation. With such energy, indeed, was this insisted on, that the legislature was actually constrained to legalise an admixture of a certain amount of oil of vitriol with vinegar, in order that thereby there might be conferred upon the latter certain keeping powers, which apparently it was supposed it did not of itself possess. Another excuse frequently made use of is, that it is perfectly impossible to supply pure articles at the current price. Finally, we have frequently the plea advanced that, after all, in many cases it does no harm—as in the addition of water to milk or whisky, or potato-starch to cocoa; therefore thus diluting these substances cannot be regarded as a criminal act.

These excuses are found to be all perfectly invalid. It is possible that one who was unacquainted with the subject, might prefer such things as bright green peas or pickles to those which were more of a yellow tint. If, however, he were informed—as he certainly should be—that the bright, fresh-looking article owed its taking appearance to the presence in it of a poisonous copper salt, it is impossible to suppose that he would still elect to be supplied with it. As to admixtures being improvements, this is of course largely a matter of opinion, but it is worthy of consideration in this connection that the articles which are added by way of improvement are always very much cheaper than the articles which are supposed to have been improved. Thus coffee used to cost about two shillings per pound, while chicory cost about fourpence. Mustard cost also about two shillings per pound at a time when flour, by the agency of which the mustard is improved, cost about one penny. With reference to the statement that admixture is necessary for the preservation of certain articles, if this is true at all, it is true of very few articles indeed. That it does not apply to vinegar is abundantly proved by the fact that the vinegar now made by most if not all of the better manufacturers does not contain a drop of sulphuric acid. The statement that adulteration is rendered necessary because the public refuse to pay a fair price for pure articles, is manifestly absurd, for it is the traders and not the public who fix the price; and if a trader were only mindful to inform his patrons that, while the purity of the less costly articles sold by himself and his brethren in trade could by no means be guaranteed, that of

those which were a little higher in price was undoubted, he would not have reason long to complain of a want of demand for unadulterated wares. As to such an adulteration as the admixture of water with milk doing no harm, as well might it be said that selling milk by means of a measure which only holds half as much as it is represented to hold, does no harm. We are not thereby poisoned, but we are certainly defrauded as much in one case as in the other.

The objects of employing different materials in the adulteration of food may be said to be three in number. First, for the purpose of increasing the bulk or weight of the dearer article; as, for example, when water is added to milk or whisky, or when chicory is added to coffee, or flour to mustard, or butcher fat to butter. Second, to brighten its colour, or to alter or improve its appearance; as in the case of the addition of certain metallic compounds to preserved fruits or vegetables, or the addition of barley-meal to oatmeal, or of alum to bread. Third, to increase its pungency or alter its flavour; as, for example, when pepper is added to ginger, artificial flavourings to wine or to alcohol, as is done in the manufacture of spurious liquors, such as imitation brandy, &c.

As to the means which the public possesses of preventing the sale of adulterated food, it may be said that before this crime against society can effectually be put an end to, we must be able to do two things. First, we must be able satisfactorily to detect adulteration, however skilfully it may have been done; and second, we must be able to inflict on those proved to have been guilty of the crime such penalties as will render the practice of it unprofitable.

As the detection of the fraud and the consequent exposure often forms in itself the most salutary form of punishment, the subject of the detection of food adulteration becomes a most important one. It is effected mainly by two agencies, chemical analysis and microscopical examination. They are employed for this purpose by a body of well-educated, highly trained men, known as public analysts, one of whom is to be found in almost every town of any importance. The duties of these officials, as well as the mode in which they are appointed, will be described in the article ANALYST. Public analysts have not as yet been very long in existence, but the amount of work which they have already done in the way of checking adulteration of food is very great.

It was not until the year 1860 that any general act of parliament dealing with food adulteration was passed into law in Great Britain. Previous to that date, special statutes applying to certain specified articles, such as tea, coffee, bread, and wine, were in force; but the main object of these enactments was to prevent the defrauding of the revenue, the health and protection of the purchaser being apparently a matter of secondary importance. The Act of 1860 did not seem to produce much result, although it remained in force for twelve years. In 1872 another act was passed, which, however, as it was supposed to have been the means of inflicting many real hardships on retail dealers, was superseded by the 'Sale of Food and Drugs Acts' of 1875 and 1879. It is these acts which constitute the existing law on the subject of food adulteration. They are, no doubt, in many respects better than the previous acts, but they are still far from being perfect. One of their most glaring and palpable defects is, that though they lay down with commendable minuteness of detail the mode of proving adulteration, together with the penalties to be inflicted when adulteration is proved, they do not, except in the case of one or two descriptions of spirituous liquors, say what adulteration is. It is

really therefore left to the analyst to define (except in a certain general sense) what constitutes adulteration. Analysts, it so happens, are not all at one on this point, so that it is not by any means an impossible circumstance that a substance which might be found to be adulterated, and for the sale of which a man might be fined or imprisoned in one county, would be decided in the adjacent county to be quite pure. What is obviously required in order that the act may be more workable and useful, is that adulteration should be defined in exact and precise terms. The act should set forth exactly what is to be considered as constituting adulteration in each separate article of food, so that when an analysis is obtained, there will be no doubt as to whether the article is pure.

The Sale of Food and Drugs Act, 1899, is an amending act dealing principally with dairy produce. It simplifies previous acts, and generally prohibits the importation or sale of any adulterated or impoverished article of 'food' (which has a new and very wide interpretation) unless in a tin or case with a true description of the contents. It also provides for imported dairy produce being sampled at the port of entry, so that, when necessary, action may be taken against the adulterator through the importer, instead of against the retailer. Stringent changes are made with regard to milk, butter, and margarine (see subsections *Milk*, *Butter*). Penalties for offences under the acts are increased, and additional stringency introduced into their application. The penalty for a first offence is £20; second, £50; third and subsequent, £100, and three months' imprisonment may be added if culpable personal default is proved. The following list, includes the more important of the substances often sold in an impure condition.

Milk is not only a most important article of food, but is the one most frequently subjected to adulteration. That it should be so we can easily understand. To conduct the business of a milk-seller but little capital is required; the trade is therefore largely in the hands of the lower class of traders. Then again, the admixture of water with milk, or the abstraction of cream, is not only very easy to perform, but it is also, unless by chemical analysis, very difficult to detect. The two forms of sophistication just mentioned are the only ways in which milk is ever adulterated. All the sensational stories of sheep's brains and chalk being used for this purpose are purely apocryphal. But though seemingly simple, and as compared with adulteration of other substances, tolerably harmless, this practice of reducing the quality of milk is really a very serious affair. Of all forms of food, not even excepting bread, milk is the one most largely used. In London alone, very nearly one and a half millions of money used to be annually paid for milk; and of this sum—according to a government return—about one-twentieth part, or from £70,000 to £80,000, was paid for water sold as milk. Judging from official reports made by analysts in different parts of the country, the practice of adulterating milk is carried on extensively in most, if not all, the large towns in the kingdom.

The detection of adulteration in milk, unless by means of chemical analysis, is a very difficult matter. It may be done in a rough way either by taking the specific gravity of the milk, or by ascertaining how much cream it will throw up. The former operation is carried out by plunging into the milk, at a temperature of 60° F., an instrument called a Hydrometer (q.v.), which sinks in the milk to a greater or less extent, according as the specific gravity is high or low. The second operation is carried out by placing a quantity of the milk to be tested in a long narrow glass tube,

closed at one end, which stands in an upright position, and is graduated into a hundred divisions. Enough milk having been poured in to occupy a hundred divisions, it is allowed to repose in the tube for at least twelve hours. Under these circumstances, the milk will throw up a certain proportion of cream, the exact amount of which can be easily read off by means of the graduated divisions. Good pure milk will throw up a sufficient amount of cream to occupy from twelve to fourteen divisions of the scale, and such milk should have a specific gravity of from 1029 to 1032. Milk from which the cream has been removed will, on the other hand, throw up much less cream than fourteen per cent.; and milk which has been adulterated by being simply mixed with water, will show a lower specific gravity than that given above. The act of 1899, already referred to, increases the penalty for selling condensed, skimmed, or separated milk, not labelled as such, to £10.

Bread.—Bread and sugar are the purest forms of food with which the public are at present supplied. The only adulteration which we now occasionally find in bread is alum, and possibly occasionally an excessive amount of common salt. The former is added for the purpose of communicating an admired white appearance to the bread, and the latter in order that it may retain an undue proportion of water. The alum, it is alleged, is often added by the miller in order that his inferior produce may yield bread having the appearance of that made from flour of a higher class. Both of these forms of adulteration are to be severely reprobated. Alum, according to many authorities, has the effect of seriously impairing the digestibility of bread; and salt added knowingly in excess of what is necessary is a fraud, whether the allegation that it causes the bread to retain water be true or not.

Alum may be detected in bread by laying a piece about two inches square upon a saucer, and then pouring upon it a small quantity of tincture of logwood, which has previously been mixed with its own bulk of carbonate of ammonia solution. If alum be present, the bread will turn blue by this treatment, whereas, if it be free from any admixture of this kind, it will become pink. Other substances besides alum which might be present in bread, have the effect of producing a blue colour with logwood, so that all we can certainly say as the result of this test is, that if a blue colour is produced, the bread is not pure, and that the impurity most probably is alum.

Other substances said to be used for adulterating bread are rice-flour, bran-flour, potatoes, borax, sulphate of copper, sulphate of zinc, chalk, and carbonate of magnesia. These, however, if they are ever employed at all, are employed to a very limited extent only; and in England in recent times, no conviction has been obtained except for admixture of alum.

Coffee is now extensively adulterated, inasmuch that it is becoming a difficult matter to obtain it free from admixture. The material most commonly used for adulterating coffee is ground chicory-root. It is used for this purpose in enormous quantities, 40 or 50 per cent. being no unusual amount to find in coffee as frequently sold; and occasionally as much as 70, 80, or even 90 per cent. has been shown to be present. When coffee cost about two shillings per pound and chicory about fourpence, the temptation to sell a mixture of the two as coffee was very strong. As already mentioned, it is legal to sell the mixture if labelled as such. Chicory may be detected in coffee by allowing a few grains of the suspected article to fall into a glass of cold water. If the coffee is pure, almost all the little

particles will, after one or two minutes, remain hard, and will continue to float on the surface, communicating very little colour to the water. If, on the other hand, chicory or any similar foreign substance be present, many of the little particles will become quite soft, and they will sink to the bottom, colouring the water more or less brown.

Cocoa is largely adulterated with sugar, arrow-root, and other starchy matters, with the view of concealing the cocoa-fat and enabling the powder to mix easily with boiling water.

Butter used to be extensively adulterated, and occasionally materials were sold as butter which contained very little or no butter at all. The original article called *butterine* was a poor compound of animal fats, manipulated with salt and milk, with or without a mixture of real butter, and was too often sold as butter. Owing to the stringency of the acts dealing with food adulteration, and particularly of the act of 1899, already referred to, this is no longer possible. The substance called *margarine*, which has superseded butterine, is, owing to greatly improved manufacture, a much superior article, and is really what it professes to be—a cheap substitute for butter, and, properly prepared, not an injurious substitute. By the act of 1899 the Margarine Act of 1887 is extended to include margarine-cheese and other products, and further and very stringent precautions are taken against their being imported or sold unless properly labelled as such. As a further precaution against its being sold as butter, margarine must not have more than 10 per cent. of real butter in its composition. The only adulterations now found in butter are boric preservatives and colouring matter.

Sugar is usually sold in a state of great purity; it should not have a damp appearance; it should have a pure, sweet taste; it should dissolve completely in cold water; and it should leave only a very small residue or ash when it is burned.

Tea was formerly much more extensively adulterated than it is at present. The only form of adulteration which we encounter in these days is in the so-called faced tea. This is nothing more than black tea, possibly not of a very high class, to which a fictitious appearance has been communicated by means of such things as indigo, Prussian blue, French chalk, plumbago, and lime being made to adhere to the surface of the leaf. This certainly is not a very serious form of adulteration, and it is very rapidly decreasing. When tea is heavily faced, the facing material may be detected by removing a portion of it either by friction on a soft piece of white cloth, or by digesting the leaves for a few minutes in a small quantity of warm water.

Oatmeal is occasionally adulterated with barley-flour, added to give a whiter appearance—to make the meal from damaged or poor oats look as if made from a better quality. The addition may be ascertained by means of the microscope. The starch granules of barley are large and somewhat oval; those of oats are smaller and angular.

Rice, properly of a creamy white, is, to meet an unreasonable demand for 'dead whiteness,' coated with a blue pigment such as indigo or Prussian blue.

Whisky is generally supposed to be extensively adulterated. This, however, is a mistaken belief. It is frequently sold when it is too new and not properly matured, and it is occasionally rather freely watered by some of the smaller retailers. Any other form of adulteration is, however, extremely rare. The strength can be ascertained by means of the hydrometer.

Brandy is a preparation resulting from the distillation of wine. There can be little doubt, however, that most of the brandy made in this country

is simply a mixture of spirit with various flavouring materials, including, possibly, a small quantity of genuine brandy.

Wine.—The stronger wines, before they are imported, are generally 'fortified' by the addition of a certain amount of spirit. It is also alleged that wines are frequently coloured with various colouring matters. While this may be true of some of the very low-priced wines, it seems that, on the whole, wine for which a fair price has been paid, and which has been obtained at a respectable establishment, is fairly pure. A satisfactory test of the purity and quality of wine, and of similar spirituous liquors, cannot be made without employing somewhat complicated chemical processes.

Malt Liquors.—These vary in strength very considerably, from Scotch ale containing nearly 9 per cent. of alcohol, to table-beer containing sometimes as little as 2 per cent. Now that the use of other bitter principles than that derived from hops has been legalised, only such bitter substances as are deleterious can be regarded as adulterations. Picric acid is certainly a poison, and it has been detected in beer. Picrotoxin, the poisonous principle of *Cocculus indicus*, is another objectionable bitter substance, the presence of which in beer has been at least strongly suspected. It is supposed that other bitter substances, such as those existing in wormwood, in aloes, in gentian, and in quassia, are occasionally used in the manufacture of beer. These, however, if they are employed at all, are made use of very seldom. It was alleged on one occasion that large quantities of strychnine were habitually used by English brewers in the production of their famous bitter beer. This absurd statement was conclusively shown to be utterly destitute of foundation. The addition of undue quantities of salt to beer is an offence for which several persons have been prosecuted. The object of adulterating beer with salt is not very apparent, unless it is done with the intention of creating thirst. Salicylic acid has also occasionally been found in beer. The salicylic acid is a powerful preservative agent, and it is added with the view of conferring special keeping properties upon the beer. Sulphuric acid, sulphate of iron, and alum were at one time added to beer or porter by the London publicans, for the purpose of giving the liquor a 'smack of age,' and producing a head. This offence seems now to be of rare occurrence. An extensive epidemic of a form of neuritis in many of the midland towns of England in 1900 was traced to the presence of arsenic in beer, which in its turn was traced to 'inverted' sugar used in the manufacture, improperly prepared with impure sulphuric acid, causing the formation of arsenic.

Honey.—Much of the material sold as honey is really not honey at all. It is composed largely of starch—sugar or glucose, and contains a small quantity of real honey in order to communicate a little of the true flavour. The raw material from which this spurious mixture is made, is prepared by acting on potato starch with oil of vitriol. The result is then mixed with a small proportion of real honey, and to detect the fraud requires the resources of a chemical laboratory, no simple test sufficing.

Golden Syrup, properly the uncrystallisable part of sugar, is sometimes mixed with—harmless, but cheap and flavourless—glucose or starch sugar.

Pickles are now sold in a much purer condition than formerly. At one time it was apparently thought necessary that certain varieties of pickles should always possess a bright green colour. As the vegetables themselves did not exhibit this in a degree sufficiently pronounced, the requisite tint was produced by the agency of

verdigris or of some other salt of copper. When such an adulteration as this does exist to any considerable extent, it may be detected by introducing the blade of a steel knife, which has been recently polished by means of fine sand-paper, into the vinegar in which the pickles are preserved. The presence of copper will be proclaimed by the appearance of a coating of metallic copper on the part of the knife immersed, after that has stood in contact with the liquid for a few minutes.

Mustard is at present adulterated to an enormous extent; indeed, it is only by the exercise of care that pure mustard can be obtained. Flour and the yellow dye-stuff, turmeric, are the usual adulterants; cayenne pepper, ginger, and charlock are not nearly in such common use.

Pepper is frequently mixed with sand, occasionally with linseed-meal and other vegetable substances, and sometimes with starchy matters, such as wheat-flour, rice-flour, sago, &c. The most common adulteration, the sand, may be detected by burning the suspected pepper until all the vegetable matter is consumed, and making an examination of the ash.

Vinegar.—The chief substances employed for the adulteration of vinegar are water and sulphuric acid; chillies and grains of paradise are occasionally made use of. Adulteration by water is best detected by estimating the amount of real vinegar acid which is present, by means of a properly conducted chemical analysis. A rough test may be made by means of the hydrometer; and vinegar which shows less than 1015 on the hydrometer scale must be held to be adulterated with water. Sulphuric acid and other mineral acids may be detected by adding to the suspected vinegar a few drops of methyl aniline violet. If the vinegar be pure, no colour will result; if it be mixed with sulphuric or any similar acid, a blue or green colour will be developed.

Cinnamon may be adulterated with galangale, or with guava or jungle bark, cunningly peeled, dried, and flavoured with waste water produced in distilling cinnamon, and with impure cinnamon-oil.

In the United States every separate state has food laws of its own. The American National Pure Food Law (1907) is not of extensive scope, and does not supersede them. Australia has paid great attention to securing the purity of its food-supply. The Federal Trade Descriptions Act of 1905 gives power to compel the placing of a true description of the ingredients contained in packages of food, drink, medicine, &c. imported into or exported from the Commonwealth; and in most of the states, dairies are systematically inspected and adulteration or false description of any article of food strictly prohibited; while New South Wales, Victoria, and South Australia have set up advisory committees by which food standards are prescribed.

The following is a list of some of the chief drugs and miscellaneous articles used in the arts and manufactures, and the most usual adulterants to be found in them:

DRUGS.	ADULTERATING SUBSTANCE.
Aconite	Exhausted dried root.
Animal charcoal	Wood charcoal and earthy matters.
Asafetida	Magnesian limestone.
Bismuth subnitrate.	Calcium phosphate.
Cape aloes	Ship's biscuit and turmeric.
Cascara bark	Other barks.
Castor-oil	Olive and lard oils.
Citrate of magnesia.	Sodium tartrate.
Gregory's mixture.	Magnesium carbonate.
Iodine	Plumbago and sulphide of antimony.
Ipecacuanha	Potato starch.
Liquorice	Sand and starch.
Myrrh	Various gums and resins.
Oil of bay rum	Oil of clove and oil of pimento.
Oil of cacao	Tallow.
Oil of lavender	Oil of spike.
Ferru balsam	Rosin, benzoin, and castor-oil.

DRUGS.	ADULTERATING SUBSTANCE.
Powdered rhubarb	Starch and turmeric.
Quinine and quinine sulphate.	Quinine sulphate, salicine, and finely picked cotton.
Salicylic acid	Acid sulphate of potash.
Sarsaparilla	Beet-root, serpentaria, podophyllum.
Scammony	Starch and chalk.
Soap	Sand, sulphate of baryta, starch, &c.
Spruce gum	Resin.
Storax	Sawdust.
Volatile oils (such as essential oil of bergamot)	Fixed oils, chloroform, alcohol, &c.

MISCELLANEOUS.	ADULTERANT.
Beeswax	Mineral matters (gypsum, sulphate of baryta, and yellow ochre), starch, resinous bodies, and paraffin.
Calicoes	Size, China clay.
Cement	Sand.
China-clay	White-lead or talc.
Colours and dyes	Cheaper colours and diluents.
Gano and other manures	Sand, oxide of iron, ochre, &c.
India-rubber	Rubber substitute, &c.
Isinglass	Gelatin.
Linen	Cotton.
Oil	Cheaper varieties.
Paper	China clay, &c.
Seeds	Inferior and cheaper seeds.
Snuff	Carbonate of soda, and moisture.
Toosacco	Nitre, glycerine, and moisture.
White-lead	Sulphate of baryta, and chalk.
Woolen cloth	Cotton fibre, shoddy.

Adultery means illicit intercourse had by a married person. In Roman and Jewish law adultery was committed only when the guilty woman was the wife of another; but in most modern systems it is adultery if either the man or the woman is married. Under the canon law, which considered marriage as indissoluble, separation was granted to either spouse for adultery. Since the Reformation, in Protestant countries adultery has been generally recognised as a ground for complete Divorce (q.v.), at the instance of either husband or wife. In Scotland this is generally referred to a statute of 1567, but it was previously announced as the common law. In England divorce could be obtained only through private statute until 1858, when the law was established which made a distinction between the sinning husband and the sinning wife. The wife's adultery was sufficient to procure the divorce for the husband; but to free the wife, the husband's adultery had (till 1923) to be shown to be complicated with incest, bigamy, gross cruelty, or two years' desertion. A decree of divorce is, in the first instance, a decree *nisi*, to be made absolute on the application of the petitioner, after the expiry of a certain period, not less than six months. In Scotland adultery or wilful desertion by either spouse will free the other. Adultery was a crime severely punishable by Jewish, Roman, and many modern systems of law, but it is doubtful how far these laws were executed. Adultery in the case of clergy leads to deprivation of office. In England and Scotland damages may be claimed by the injured husband from the paramour, and this was the case in England even before 1858, when the Divorce Court was introduced. In England, when a marriage has been dissolved by decree of divorce made absolute, it is lawful for either party to marry again, as if the prior marriage had been dissolved by death. In Scotland a statute of 1600, still in force, forbids marriage between adulterers named in the decree of divorce. See JUDICIAL SEPARATION.

In the United States, adultery is a civil injury, for which the husband of the woman can have an action of damages against her paramour. Adultery is also a crime, punishable by fine and imprisonment, with more or less severity throughout the United States.

Ad Valorem (Lat., 'according to value'), a phrase used in levying customs duties, when the duties on the goods are fixed, not according to weight, size, or number, but at rates proportioned to the estimated value of the goods.

Advancement is properly an English law term which is applied to the advancing of money by a parent to a child for some such purpose as setting him up in business. Settlements very often give a power to trustees to do this. In the case of intestate succession, in England as also in Scotland, such advances made by the parent in his lifetime must be brought into hotch-pot by the children before they can share in the distribution of the parent's estate.

Advance Note, an order for (generally) a month's wage given to sailors when they engage.

Advent (Lat. *adventus*, 'the coming'), a season of preparation for the festival of Christmas, as Lent for that of Easter. In the Greek Church, the Advent period comprises forty days; and similarly, in the earliest authentic notice of Advent, a canon of the Council of Mâcon (581 A.D.), fasting three times a week is enjoined from the feast of St Martin (11th November) to the Nativity. In England, this forty days' fast was observed even after Bede's death (735), though Gregory the Great (590-604) had restricted the season to the four Sundays of Advent, now observed in the Roman communion and the Church of England. It was common from an early period to speak of the coming of Christ as *fourfold*: his 'first coming in the flesh'; his coming at the hour of death to receive his faithful followers; his coming at the fall of Jerusalem; and at the day of judgment. The Gospels for the four Sundays were chosen to illustrate this fourfold view of Advent. The Advent season is intended to accord in spirit with the object celebrated. As Christians were called upon to prepare for the second personal coming of Christ, so they are exhorted, during this season, to look for a spiritual advent of Christ. The time of the year when the shortening days are hastening toward the solstice—which almost coincides with the festival of the Nativity—is thought to harmonize with the strain of sentiment proper during Advent. In opposition, possibly, to heathen festivals observed by ancient Romans and Germans, which took place at the same season, the Catholic Church ordained that the four weeks of Advent should be kept as a time of penitence; according to the words of Christ: 'Repent, for the kingdom of heaven is at hand.' During these weeks, therefore, public amusements, marriage festivities, and dancing were prohibited; fasts were enjoined, and sombre vestments were used in religious ceremonies. It was perhaps a natural thought to begin the ecclesiastical year with the days of preparation for the coming of Christ. This practice was introduced into the Western churches in the 6th century.

Adventists, a family of American religious sects, who look for the speedy second coming of Christ, and the commencement of the millennium. The earliest to bear the name were followers of William Miller (1781-1849), and expected the end of the world in October 1843, but repeatedly changed the date. Despite such mistakes, their numbers have steadily increased, and in 1917 amounted to 118,000 members, with 2700 organisations. The several sections or sects hold varying views on the subjects of the divinity of Christ and the annihilation of the wicked.—The 'Seventh-day' Adventists set no time for the coming of Christ. They observe Saturday as the Sabbath. Alcohol and tobacco are generally forbidden, and abstinence from pork, tea, and coffee is recommended by this body.

Advertising is usually effected by means of the ordinary newspapers, covers and fly-leaves of magazines, or of newspapers and publications specially devoted to the purpose. Advertisements, both printed and written, are still posted on church-

doors and other places of public resort, in which case they are commonly called bills or placards. The most formal kind of advertisement, and that which is employed in the case of royal proclamations and the like, is publication in the *Gazette* (q.v.); but such a publication alone is not a sufficient notice of a dissolution of partnership to free a retiring partner from debts afterwards contracted in name of the firm to persons who have before dealt with the firm. Public notifications are frequently enjoined by statute; as, for example, under Road and Bridge Acts, the Bankrupt Statutes, &c., and in certain actions—e.g. for the distribution of a succession, or where an entailed estate is being dealt with, the court orders advertisement. It is in England a criminal offence to advertise for stolen property, promising not to make inquiries, or to repay the money advanced by pawnbrokers. Persons advertising a reward for the return of any property stolen or lost, and adding words to the effect that if returned no questions will be asked, are liable to a penalty of £50. The same applies to the printer and publisher of such advertisement. Advertisements by public carriers, railway companies, and the like, are equivalent to offers whereby the advertiser will be bound to those who send goods on the faith and in accordance with the terms of the advertisement. By advertising a *General Ship* (q.v.) for a particular voyage, the master places himself on the footing of a public carrier, and is bound to receive goods for the port to which the vessel is advertised to sail. A merchant in such circumstances can insist on his goods being received, unless the ship be full, or the entire freight engaged. The contract of affreightment is completed by the advertisement, and the shipping of the goods in conformity and with reference thereto (see CHARTER-PARTY, CARRIER).—A duty on advertisements was first enacted in 1712, and in 1853 it was wholly repealed. The Indecent Advertisements Act, 1889, renders it a punishable offence to exhibit or deliver advertisements of an indecent nature. Under the Advertising Stations (Rating) Act, 1889, ground used for advertising is rateable.

Advertisements were not unknown in ancient Greece and Rome. The ruins of Pompeii and Herculaneum afford examples, the walls in the most frequented parts being covered with notices, painted in black and red. Announcements of plays and gladiatorial shows are common; and so are those of salt-water and fresh-water baths. In still earlier times, especially amongst the Greeks, a common medium of advertisement was the public crier; another, in cases of things stolen or strayed, or of injuries inflicted upon the advertiser, was an inscription affixed to the statues of the infernal deities, invoking curses upon the offender. In mediæval times, it appears that the advertising shopkeeper's chief organ was the public crier; and it was also customary for most traders to have touters at their doors. One of the very first posters 'ever printed in England was that by which Caxton announced, circa 1480, the sale of the "Pyres of Salisbury use," at the Red Pole, in the Almonry, Westminster.' The *pye* or *pica* was a table or directory of devotional services.

The early newspapers of the 17th century were slow to admit advertisements; and the first regular advertisers were booksellers, followed by dealers in quack medicines, and merchants. Books and pamphlets were advertised in 1647-48, and the *Mercurius Politicus* for November 22, 1660, had a quack advertisement which might have appeared at the present time. The *Public Advertiser* (1657) consisted almost wholly of advertisements, including the arrivals and departures of ships, and books to be printed. Soon other papers commenced to

insert more and more advertisements; and by the year 1682 newspaper advertising was well developed, chiefly through the medium of the *London Gazette*, the only paper that still exists of all those started about the middle of the 17th century. In 1785 was established the *Daily Universal Register*, which, in 1788, changed its name to the *Times*. Its establishment marks the beginning of the era of modern advertising.

It is well known that most newspapers and periodicals derive the bulk of their income from their advertisements; and when we remember that there are some 2300 newspapers and 1500 magazines issued in the United Kingdom, the enormous development of advertising may be imagined. When a stamp-duty was enforced on advertisements, the *Times* paid government in 1830 the sum of £70,000; calculated on its present sale and advertisements, what would the total now be? Advertising is now an art, and great ingenuity and activity are shown in catching the eye of the public; unless guarded, the finest scenery, rocks, and islands are not held sacred by the ubiquitous advertiser. Unhappily the facilities put in their way by the papers are frequently used by unscrupulous persons to puff their wares beyond their desert, and otherwise to mislead the public; and a question has been raised as to the morality of publishing advertisements without any assurance that the expectations held out correspond in any way to the value of the specifics lauded. The aid of painters, poets, and essayists is called in to make the advertisements attractive. Thomas Holloway, who began to advertise his pills and ointment in 1837, ultimately devoted £1000 a week to advertisements. Some English advertisers are said to spend £40,000 or £50,000 a year in this way. Altogether some eighty to one hundred million pounds a year are spent on advertising in Great Britain, and about six or seven times that amount in the world, or 7s. 6d. a head.

America is the classical land of advertising. A great impulse was given to it by the establishment of the *New York Sun* in 1833, the *Herald* in 1835, and the *Tribune* in 1841. At the beginning of the 20th century there were upwards of 20,000 newspapers in the United States; and the amount spent in advertising was estimated at \$500,000,000 a year. The proprietors of a quack medicine offered £5000 towards the gigantic statue of Liberty in New York harbour, provided they were allowed to put an advertisement on it for a year.

See *NEWSPAPERS*; Grant's *Newspaper Press* (1871); Sampson's *History of Advertising* (1874); Hatton's *Journalistic London* (1882); Coe's *Red Book on Advertising* (1904); Moran's *Business of Advertising* (1905); the *Reminiscences of Morgan Richards* (1905); T. Lewis, *The Advertisements of the Spectator* (1909); Goodall, *Advertising* (1914); and Russell, *Commercial Advertising* (1919).

Advocate (Lat. *advocatus*). An advocate is generally defined 'the patron of a cause,' though it does not appear that the 'patrons' who, in the republican era of Rome, assisted their clients with advice and pleaded their causes were called by that name. Even in the time of Cicero the term *advocatus* was not applied to the patron or orator who pleaded in public, but rather, in strict accordance with the etymology of the word, to any one who in any piece of business was called in to assist another. Under the Empire the term was used to signify persons who made it their profession to aid in the conduct of actions (Sig. 50. 13. 1). They received fees (*honoraria*) for their services, and occupied a position analogous to that of the advocate of modern times. The occupations of a juriconsult and a forensic orator seem to have differed pretty much as those of a consulting and a practising counsel do with us. They might be exercised

separately, but were generally combined. The office of the advocate or barrister who conducted the cause in public, was, in Rome, altogether distinct from that of the procurator, or attorney, or agent, who represented the client in the litigation, and furnished the advocate with information regarding the facts of the case. The distinction between these two occupations does not everywhere prevail; and in many of the states of Germany, in Geneva, in America, and in some British colonies, as, for example, in Canada, they are united in the same person, and there is a movement in Great Britain in this direction. The common arrangement is that a firm undertakes all legal business, and one partner does forensic, another conveyancing, business. The view on one side is that a qualified practitioner should be entitled to charge for his services, and to recover payment of accounts; on the other side, that the public interest requires a bar placed by custom and honourable feeling beyond the ordinary temptations of business. In England and Ireland, advocates are called Barristers (q.v.). In England the name advocate was confined to those formerly admitted by the archbishop to practise in the Court of Arches, and who formed a separate legal college. This was changed in 1857, and barristers now practise in the ecclesiastical courts. In Scotland, as in France, the more ancient name has been retained (see *ADVOCATES*). The advocates who practise under that name in the town and county of Aberdeen are, however, not advocates in this sense, but solicitors. In France, the *avocat* and *avoué* correspond very nearly to the barrister and solicitor in England.

In the United States, advocate, if used in a legal sense, is almost synonymous with counsellor. But there is in America no such distinction between the counsellor and solicitor as exists in Britain between barrister or advocate and solicitor.

Advocate, LORD. The Lord Advocate for Scotland, called also the King's or Queen's Advocate, is the public prosecutor of crimes, senior counsel for the crown in civil causes, and an officer of state of very great importance in the management of Scottish affairs. He may issue warrants for arrest and imprisonment in any part of Scotland, and possesses many other discretionary and indefinite powers. Previous to the Union, the King's Advocate had a seat in the parliament of Scotland *ex officio*; and since that event, he has been almost invariably a member of parliament. He is appointed by the crown, and his tenure of office ceases with that of the administration of which he is a member. As first law-officer of the crown for Scotland, the Lord Advocate, when in parliament, was, prior to the creation of a Secretary for Scotland in 1885, expected to answer all questions relating to the business of Scotland, and to take the superintendence of legislation for that portion of the United Kingdom, and he still largely performs these duties, especially when the Secretary for Scotland is in the House of Lords. Notwithstanding his multifarious official duties, the Lord Advocate accepts ordinary practice at the bar, and, indeed, is usually the most extensively employed practitioner connected with the party in power. He is assisted in the duties of public prosecutor by the Solicitor-general, and by four advocates, called advocates-depute, appointed by himself. His salary (since 1894) is £5000. The Crown-agent, who is a Writer to the Signet (q.v.), performs in reference to crown causes pretty much the same duties that fall to a solicitor or agent in ordinary litigation. As to the relation in which the Lord Advocate stands to the public prosecutors of crimes in the inferior courts, see *PROCURATOR-FISCAL*.

The Lord Advocate and Solicitor-general are entitled to plead within the bar. The Lord Advocate has a title to sue, and is the proper party to be sued, in civil actions on behalf of the crown and the public departments. He has full discretionary power as to the prosecution of crimes in Scotland. When the Lord Advocate declines to prosecute, it is competent for a private party who has suffered injury to do so with his concurrence or 'concourse.' When he refuses his concurrence, the High Court of Justiciary may authorise a private party to institute criminal proceedings in the High Court by way of 'criminal letters.'

It is not certain that the King's Advocate was originally authorised to act as public prosecutor in crimes; but he certainly possessed that power in 1587, and it seems to be implied in a statute of 1579. Under the existing system all prosecutions for the public interest by way of indictment, whether before the High Court of Justiciary or before a sheriff and a jury, proceed in the name of the Lord Advocate, and he and the subordinate public prosecutors acting under his control are directly responsible for the institution, preparation, and conduct of such prosecutions. On the death of a Lord Advocate during his tenure of office, indictments may be raised in name of the Solicitor-general then in office, until another Lord Advocate is appointed. In any case of sudden or suspicious death in Scotland, the Lord Advocate is empowered, by the Fatal Accidents Inquiry Act, 1906, to direct a public inquiry into the death and its circumstances. Special statutes confer on the Lord Advocate the right and duty of intervening in the public interest in various judicial proceedings of a civil character. Thus he may intervene in actions of divorce where there is any suspicion of collusion, in the settlement by the court of any scheme for the administration of charitable or other permanent endowments, and in certain bankruptcy proceedings. So proceedings for the revocation of a patent must be in the form of an action of reduction at the instance of the Lord Advocate, or of a party having an interest with the concurrence of the Lord Advocate. The act (48 and 49 Vict. chap. 61) which instituted the office of Secretary for Scotland expressly provides (sec. 9) that none of the provisions of the act shall prejudice or interfere with any rights, powers, privileges, or duties vested in the Lord Advocate. See G. W. T. Omond, *The Lord Advocates of Scotland* (2 vols. 1883; and second series, 1914).

Advocates, FACULTY OF, in Scotland. The constitution of this body, like the name by which its members are known, was unquestionably derived from France. The profession seems to have existed in Scotland from a very early time; and in 1424 a statute was passed for securing the assistance of advocates to the poor. This institution has remained with little alteration to the present time (see POOR'S ROLL). But though existing as a profession, the advocates of Scotland did not form a faculty or society till the institution of the College of Justice (q.v.) in 1532. At first their number was limited to ten, but there is now no limit. From the improvements which have been made in the sheriff courts, and from other causes, the amount of litigation in the Court of Session has tended to diminish, and the continued accession of new members to the Faculty of Advocates is to be accounted for only by the fact that the bar is still regarded as the regular avenue to public and official life in Scotland. The Faculty was at one time a highly aristocratic institution, but now it is recruited from all classes of society. The Scottish advocates have always taken a liberal view of improvements in the law and legal institutions; and the chief reforms in these directions are due to their initiation or support. Two examinations are

imposed on candidates for admission, the one in general scholarship, the other in law—the first, however, being dispensed with if the intrant is Master of Arts of a British university, or has a satisfactory degree of a foreign university. Otherwise an examination takes place before a committee of the Faculty on (1) Latin; (2) Greek, or one modern language—French, German, Italian; (3) Ethics or Metaphysics, and Logic; (4) Mathematics, or Natural Philosophy, or Chemistry; (5) History. After the expiry of a year, the qualified intrant may go in for his private examination on law. The examiners, however, cannot take him on trial if during the year he has been engaged in any trade, business, or profession. Proof of attendance on the law-classes in a Scottish university is also requisite. An intrant who has obtained the degree of LL.B. from a Scottish university is exempted from examination. An advocate is entitled to plead in every court in Scotland, civil, ecclesiastical, or criminal, superior or inferior; and also before the House of Lords. A party may manage his own cause in the Court of Session (q.v.), so far as oral pleading is concerned, but, subject to a few exceptions, every paper in the cause must be signed by an advocate. There is a widows' fund belonging to the body, which is also regulated by statute. The supreme judges of Scotland and principal sheriffs are always, and the sheriff-substitutes generally, selected from the bar. The fees on admission to the Faculty of Advocates are about £355, the great bulk of which is devoted to the purposes of the Advocates' Library (q.v.). The Faculty elect from time to time a distinguished advocate as Dean of Faculty, who claims precedence at the bar over the law-officers of Scotland.

Advocates' Library, in Edinburgh, was established by Sir George Mackenzie of Rosehaugh, Dean of the Faculty of Advocates, in 1682. In 1684 the first librarian was appointed, his salary in 1686 being fixed at 400 merks per annum. In 1700 the collection narrowly escaped destruction by fire, after which it was removed from the Parliament Close to the ground-floor of the Parliament House, which it still occupies. By the first Copyright Act (1709), the privilege of claiming a copy of every book entered at Stationers' Hall was conferred on the Advocates' Library, and is still retained by it. The number of volumes in the library in 1692 was 3140; it is now about 700,000. The MSS. number some 3000 volumes, and relate principally to the civil and ecclesiastical history of Scotland, to genealogy and heraldry, together with poetry, bibles, prayer-books, liturgies, and copies of the Latin and Greek classics. The catalogue of 1853-79 is a complete list of all printed books in the library at the end of 1871. Although the library belongs to the Faculty of Advocates, it is freely made accessible to all engaged in literary work. The management is by a keeper and staff of assistants, working under a board of curators. Among keepers have been Thomas Ruddiman, David Hume, Adam Ferguson, and Samuel Halkett. In 1922 the library was offered to the nation as the basis for a National Library of Scotland, and in 1923 a gift of £100,000 by Sir (then Mr) Alexander Grant made the acceptance of this offer possible.

Advocation, a name formerly given to the process of Appeal (q.v.) from a Sheriff Court in Scotland to the Court of Session. It was abolished as a mode of civil appeal in 1868. But, in criminal procedure, advocacy to the Court of Justiciary is still a competent method of bringing the proceedings of summary criminal courts under review.

Advocatus Diaboli ('the devil's advocate'), a popular, somewhat jocular, name given to the *promotor fidei*, the person appointed to state

the objections to any proposed canonisation in the Roman Catholic Church. An examination of the past life of the candidate takes place, and in this process the *advocatus diaboli* brings forward all possible objections; while, on the other side, the *advocatus Dei* ('God's advocate'), or *promotor causæ*, undertakes the defence. See BEATIFICATION, CANONISATION.

Advowson, the right of presentation to a church or ecclesiastical benefice in England. Advowsons are either *appendant* or *in gross*. Lords of manors were originally the founders, and, of course, the patrons of churches; and so long as a right of patronage continues annexed or appended to the manor, it is called an *advowson appendant*. Such rights are conveyed with the manor as incident thereto, by a grant of the manor only, without adding any other words. But where the advowson has been once separated from the manor, it is called an *advowson in gross*, or at large, and is annexed to the person of its owner, and not to his manor or lands.

Advowsons are of three kinds—(1) Collative, where the bishop is patron. When this is the case, rights of patronage are seldom grossly abused; though clergymen complain that the bishops are accustomed to appoint their own relatives and dependents, without due regard to the principle of promotion by merit. (2) Donative, where a private patron disposes of the living without presenting his nominee to the bishop. This form of patronage is generally condemned. No benefice with cure of souls is now held as a donative; but the number of donatives is small. (3) Presentative, where the patron presents to the bishop, who may refuse to institute a person whom he has good—i.e. legally sufficient—reason to regard as unfit, in point of learning, doctrine, or morals. If the patron is a Jew, he cannot present, and his right lapses to the Archbishop of Canterbury. If the patron is a Roman Catholic, his right lapses to the university of Oxford or of Cambridge, according to the county in which the living is situated.

An advowson is regarded as real estate, and may be disposed of as freely as other rights of property, subject to the rules of law relating to simoniacal contracts. An agreement to sell an advowson or next presentation while the living is vacant is simoniacal, and therefore unlawful. By an act of 1713, clergymen are forbidden to buy next presentations for themselves; but it has been held that the act does not apply to the purchase of a life estate in the advowson. The traffic in livings is conducted as a regular branch of agency business. It often happens that a clergyman, who owns the advowson of his living, offers it for sale, 'with immediate possession'—in other words, he agrees to resign as soon as the sale is complete, that the purchaser may present himself or the person for whom he has purchased the living; and bishops acquiesce in these illegal transactions, because they see that no good will be done by compelling the vendor to remain in charge of the parish. Scandal is also caused by the advertisements put forth by the 'clerical agents' who have livings for sale. By way of inducement to purchasers, they state that 'there is a good trout stream in the neighbourhood'—'there are no charities to support'—'the weekly attendance in church is very small'—'there is no house, and consequently no obligation to reside in the parish.' If the incumbent remains in possession, it is explained that he is extremely old, and in feeble health. Sometimes the living is offered at an enhanced value, because the church or the parsonage has been improved by means of a public subscription, or of a grant from Queen Anne's Bounty.

The abuses connected with the traffic in livings

have led to many parliamentary debates and inquiries. In 1879 a royal commission sat to take evidence on the subject; and in 1886 the Archbishop of Canterbury introduced a reforming bill into the House of Lords. Those churchmen who favour reform have generally disclaimed hostility to private patronage as an institution. They believe that patronage, when properly exercised, tends to bring a wholesome lay influence to bear on the clergy; they prefer that patronage should be in private and not in episcopal hands; and they are opposed to popular election, which, they say, works badly in the few parishes where the minister is chosen by the ratepayers. They are also well aware that parliament is not easily persuaded to meddle with rights which have been acquired by the payment of hard cash. But they desire to confer on the parishioners the right of raising objections to an unfit presentee, and on the bishop the right of refusing institution on any ground which implies unfitness for pastoral duty. Advocates of religious equality have sometimes opposed such legislation, holding that church reformers claim powers of self-government inconsistent with the position of a state church. The Benefices Act of 1898 provides that advowsons shall not be sold by auction except along with landed estate adjacent to the benefice, and makes various other restrictions on the transfer of patronage.

Adytum, the sanctuary or innermost part of an ancient temple, which none but priests could enter, and from which oracles were delivered.

Ædiles, Roman magistrates, who had the care of public buildings (*ædes*), especially the temples, and also attended to the cleansing and repairing of the streets, the preparations for funerals, public games and spectacles, the inspection of weights and measures, the regulation of markets, &c.—At first there were only two ædiles, who were chosen from the plebeians, and styled *Ædiles plebis*; afterwards two others, styled *Ædiles curules*, were chosen from the patricians (366 B.C.), and Julius Cæsar appointed a new order of *Ædiles cereales* to take charge of the public granaries.

Ædui, a powerful tribe in ancient Gaul between the rivers Liger (*Loire*) and Arar (*Saône*), who at first formed an alliance with Cæsar, but joined the rest of the Gauls under Vercingetorix. See CÆSAR.

Ægean Culture is a name given to the earlier stage of the remarkable pre-Hellenic civilisation recently revealed by excavations at Mycenæ, Tiryns, and especially in Crete, and illustrated by buildings, pottery, bronzes, and pictures. The various stages in Crete, called Early, Middle, and Late Minoan, may be dated round about 2400, 1800, and 1200 B.C., the last broken up by the invasion of the Dorians from the north about 1100 B.C. See CRETE; GREECE; Burrows, *The Discoveries in Crete* (1907); Hall's *Ægean Archaeology* (1914); and the reports and works of Sir A. Evans.

Ægean Sea. See ARCHIPELAGO.

Ægeus, a king of Athens, son of Pandion, and father of Theseus (q.v.). When Theseus sailed to Crete, he promised his father to hoist white sails on his return as a signal of safety, but forgot his promise in the joy of triumph; and his father, anxiously waiting, seeing only black sails on his son's returning ship, and believing that he had perished, flung himself into the sea, from him named the Ægean.

Ægina, a Greek island 33 square miles in area, in the Gulf of Ægina (the ancient *Saronicus Sinus*). It is mountainous, with deep valleys and chasms. The modern town of Ægina stands on the site of the ancient town, at the NW. end of the island. There are considerable remains still

left of the ancient city, and the ruins of solidly built walls and harbour moles still attest its size and importance. The island contains about 7000 inhabitants. The most ancient name of the island was Cēnone, and the Myrmidons dwelt in its valleys and caverns. For a century before the Persian war it was a prosperous state; during this period it was also the chief seat of Greek art. Its sailors covered themselves with glory at Salamis. The Athenians in 429 B.C. expelled the original inhabitants, whose language and style of art were Dorian.

ÆGINETAN SCULPTURES.—Ægina holds an important position in the history of Greek art. On an eminence in the N.E. of the island stand the ruins of a temple—of Aphaia or Rhea according to Furtwängler—whence in 1811 there were excavated a series of statues which are now the most remarkable ornaments of the Glyptothek at Munich. One group represents a combat of Greeks and Trojans for the body of Achilles. The figures are true to nature, with the structure of bones, muscles, and even veins, distinctly marked; but there is no individuality, all the faces having that uniform forced smile which is characteristic of all sculpture before the time of Phidias. Probably they date from not more than fifty years before Phidias.

Ægineta, PAULUS. See PAULUS ÆGINETA.

Ægis, the shield of Zeus, which had been fashioned by Hephestus (Vulcan). When Zeus was angry, he waved and shook the ægis, making a sound like that of a tempest, by which the nations were overawed. It was the symbol of divine protection, and became, in course of time, the exclusive attribute of Zeus and Athene.

Ægisthus, son of Thyestes, and cousin of Agamemnon. He did not accompany the Greeks to Troy, and during the absence of Agamemnon, lived in adultery with Clytæmnestra, his wife. He assisted her in murdering her husband on his return, but was himself put to death seven years later by Orestes, son of Agamemnon. This is the account given by Homer: the tragic poets make Clytæmnestra alone murder Agamemnon, her motive in Æschylus being her jealousy of Cassandra; in Sophocles and Euripides, her wrath at the death of Iphigenia. Later writers also describe Ægisthus as the son of Thyestes by unwitting incest with his daughter Pelopia.

Æglé, a genus of Rutaceæ (see AURANTIACEÆ), of which *Ægle marmelos* produces a fragrant, delicious, and wholesome Indian fruit resembling the orange, called Bael-fruit or Bhel-fruit. In an imperfectly ripened state, it is an astringent of great effect in cases of diarrhoea and dysentery. The root, bark, and leaves are of similar properties. A perfume has been prepared from the rind of the fruit, which also furnishes a yellow dye, while the seed yields a cement.

Ægospot'amoí (Gr., 'goat-rivers'), in the Thracian Chersonesus, is famous for the defeat of the Athenian fleet by the Lacedæmonians under Lysander, which put an end to the Peloponnesian war, and to the predominance of Athens in Greece, 405 B.C.

Ælfric (called *Grammaticus*, 'the Grammarian'), a voluminous old English writer about the close of the 10th century, whose history and whose personality even are alike involved in obscurity. It is known that he was a pupil of Æthelwold, most likely at the Benedictine monastery of Abingdon, and it is more than probable that he accompanied his master on his advancement to the see of Winchester. He was appointed to rule over the new monastery at Cerne, and afterwards became abbot of Ensham. He has been sometimes, as by Wright,

Dean Hook, and Mr Freeman, confounded with Ælfric, the Archbishop of Canterbury from 995 to 1005; and by others, as Wharton and Thorpe, with Ælfric, the Archbishop of York from 1032 to 1051. The grammatical works ascribed to Ælfric are his Latin and English grammar and glossary, printed by Somner at Oxford in 1659, included in Professor Zupitza's *Sammlung Englischer Denkmäler* (Berlin, 1880); and his *Colloguunum*, a series of dialogues containing interesting descriptions of common life, in Latin, with English interlinear translation. His most important work is his collection of *Homilies*, 80 in number, edited by Thorpe for the Ælfric Society (1844-46). They are short and vigorous, and attracted great attention at the time of the English Reformation. The 'Paschal Homily,' as well as two or three others, has been often appealed to in controversy to prove that the doctrine of the early church in England differed in some important respects from that of the later Roman Church. Among his other works are a treatise on the Old and New Testaments, and an abridgment of the Pentateuch and the Book of Job.

Ælianus, CLAUDIUS, a native of Præneste in Italy, who studied and taught rhetoric in Rome at the end of the 2d century A.D., and was styled the 'Sophist.' Two of his works remain—the *Varia Historia*, in fourteen books (containing biographical notices, anecdotes, &c.); the other, in seventeen books, *De Natura Animalium*, on curiosities of animals and animal life.

Emilian Provinces. See EMILIA.

Emilius Paulus was the consul who fell in the battle of Cannæ in 216 B.C. His son, Lucius Æmilius Paulus (or Paullus) Macedonicus, inherited his father's valour, and enjoyed an unwonted degree of public esteem and confidence. In 168 B.C. he was elected consul for the second time, and intrusted with the war against Perseus, king of Macedon, whom he defeated in the battle of Pydna. The son of the conqueror of Macedon, adopted by Scipio, was known as SCIPIO ÆMILIANUS.

Æne'as, the hero of Virgil's *Æneid*, was, according to Homer, the son of Anchises and Aphrodite (Venus), and ranked next to Hector among the Trojan heroes. The traditions of his adventures before and after the fall of Troy are various and discordant. Virgil gives the following version: Æne'as, though warned by Priam in the night when the Greeks entered Troy, to take his household gods and flee from the city, remained in the contest until Priam fell, when, taking with him his family, he escaped from the Greeks, carrying his aged father on his shoulders, but in the confusion of his hasty flight, lost his wife Creusa. His filial affection to his father earned him the name of the 'pious Æne'as.' Having collected a fleet of twenty vessels, he sailed to Thrace, where he began building a city, but was terrified by an unfavourable omen, and abandoned his plan of a settlement there. A mistaken interpretation of the oracle of Delphi now led him to Crete; but from this place he was driven by a pestilence. Passing the promontory of Actium, he came to Epirus, and then continued his voyage to Italy and round Sicily to the promontory of Drepanum on the west, where his father Anchises died. A storm afterwards drove him to the coast of Africa, and landing near Carthage, he was hospitably received and entertained by Queen Dido. His marriage with Dido was prevented only by an express command of Jupiter that he must return to Italy. The hero sailed away, leaving the unhappy queen to despair and death by her own hand. During his stay in Sicily, where he celebrated the funeral of his father, the wives of his companions and seamen, weary of long voyages without certainty of finding a home,

set fire to his fleet. After building the city Acesta, he sailed for Italy, leaving behind him the women, and some of the men belonging to his fleet. On landing in Italy, he visited the Sibyl at Cumæ, and received intimations of his future destiny. Then, sailing along the Tiber, and landing on the east side of the river, he found himself in the country of Latinus, king of the Aborigines. Lavinia, the daughter of Latinus, had been destined to marry a stranger; but her mother had promised to give her in marriage to Turnus, king of the Rutuli. A war ensued, which terminated in the marriage of Æneas with Lavinia. His landing in Italy occurred seven years after the fall of Troy. Many of the episodes in the story, as his meeting with Queen Dido at Carthage, are irreconcilable even with mythical chronology. Iulus or Ascanius, son of Æneas and Creusa, was claimed as their eponymous ancestor by the Julian gens at Rome; hence constant allusions to the divine ancestress of Augustus occur in Virgil, Horace, and other poets of his time.

Æneas Silvius. See PIUS II.

Æolian Accumulations is the term often applied to formations which are due to the action of the wind, such as the sandhills or dunes of many maritime regions, and the similar hillocks which occur in desiccated areas, such as those of the Sahara, Arabia, Utah, Arizona, &c.

Æolian Harp (i.e. 'the harp of Æolus'), a simple musical instrument which produces harmonic sounds when placed in a current of wind. It is formed by stretching eight or ten catgut strings of various thickness, all tuned in unison, over a wooden shell or box, made generally in a form sloping like a desk. The sounds produced by the rising and falling wind, in passing over the strings, are of a drowsy and lulling character, so that the Æolian harp is most fitly introduced by Thomson into the *Castle of Indolence*. St Dunstan is said to have invented it; modifications were Schnell's Anemochord (1789), and Herz's Pianoéolien (1851).

Æolian Islands. See LIPARI.

Æolians, one of the principal races of the Greek people, who were originally settled in Thessaly, from which they spread and formed numerous settlements in the northern parts of Greece and in the west of Peloponnesus. In the 11th century B.C., some part of them emigrated to Asia Minor, where they founded on the NW. coast in Mysia and the adjacent isles (hence called Æolia) more than thirty cities; among them Smyrna, and Mitylene in the island of Lesbos, where the Æolic dialect of the Greek language chiefly developed itself in the forms employed in the poetry of Alcæus and Sappho. The Æolians shared the fate of the other Greek colonies in Asia Minor. First oppressed by the Lydian kings, then deprived of their independence by the Persians, they became a portion of the great empire founded by Alexander, and were ultimately absorbed in the Roman empire.

Æolipile, a hollow metallic ball from which, when heated, steam issues by orifices in two tubes, so as to turn it. It was invented by Hero of Alexandria (q.v.). See STEAM-ENGINE, STEAM-TURBINE.

Æolotropy (from Greek words for 'changeful' and 'turning') is the opposite of *isotropy*, and implies change in the electrical, optical, or other physical properties of bodies in consequence of change of position—as when the refractive property of a transparent body is not the same in all directions. The æolotropy of Iceland spar is a notable instance. A body may not, however, be equally æolotropic in all respects; it may be isotropic in one or more qualities, and æolotropic in others. See REFRACTION, POLARISATION.

Æolus, the ruler and god of the winds, who reigned over the group of islands NE. of Sicily, named from him the Æolian Islands, now the Lipari group. The dominion over the winds was intrusted to him by Zeus, and he kept them inclosed in a cave under a mountain. He must not be confounded with his ancestor of the same name, who was ruler of Thessaly and the mythical founder of the Æolic branch of the Greek race.

Æon, a Greek word properly meaning 'age' or 'eternity,' but used by the Gnostics to mean an emanation from God, which became in some degree a separate spiritual existence, and presided over spheres of the world or phases of the world's history. See Gnosticism.

Æpyornis (Gr., 'tall bird'), the name given to a great wingless bird, whose remains occur in Post-tertiary deposits in Madagascar. Its sub-fossil eggs are 13 to 14 inches in diameter, and have the capacity of three ostrich eggs. There appear to have been two or three species of æpyornis, one of these being as large as, or larger than, the *Dinornis* (q.v.).

Æqui, a warlike tribe of ancient Italy who inhabited the upper valley and hills to the SE. of the river Anio, on the eastern border of Latium. Together with the Volsci, a kindred tribe, they waged constant warfare with the young Roman republic, sometimes carrying their raids to the very gates of the city. In 446 B.C. they appeared for the last time before the city, and in 418 they were dispossessed of their great stronghold on Mount Algidus. Their last struggle with Rome began in 304, and ended with their complete subjugation.

Aerated Bread is bread not fermented with yeast, but mechanically charged with carbonic acid gas, the gas being derived usually from carbonic acid water. See BREAD.

Aerated Waters is the name applied to the large class of beverages which are rendered sparkling by dissolving in them carbonic acid under pressure. The term does not include champagne or fermented ginger-beer, or any other carbonated beverage in which the carbonic acid gas is produced by the natural process of fermentation. Carbonic acid dissolves readily in water, that liquid absorbing at the ordinary atmospheric pressure and temperature about its own volume of the gas. Under pressure, however, as when the gas is forced into a strong vessel containing the water, it absorbs many times its own volume; and when the pressure is released, the extra amount of carbonic acid escapes, rendering it sparkling or effervescent. The water does not, however, give off all the extra gas at once; hence the well-known experiment of dropping a piece of cork into a tumblerful of lemonade, when immediate effervescence takes place, and carbonic acid is given off. All agitation, or the presence of particles of dust, favours the disengagement of the gas, and so it is that in drawing lemonade from a *siphon* (see below), the tumbler is filled with froth to an extent not noticed in pouring from a bottle. In this case, the rapidity of discharge through a narrow tube causes immediate liberation of a large volume of the gas, producing the froth referred to. The varying solubility of carbonic acid at different temperatures and pressures explains why siphons or bottles which have been kept in a cold place appear to be deficient in gas, when in reality the gas is only kept in solution by the low temperature of the water.

It would be beyond the scope of this article to describe the various forms of apparatus used in the production on the large scale of aerated water. Essentially the process consists in dissolving carbonic acid gas in water under pressure, and bottling the liquid under pressure. The carbonic acid gas is either obtained by the combustion of

coke, or by the action of sulphuric acid on chalk. In the former case the gas is supplied in a liquefied state, and is contained in steel cylinders capable of standing high pressure. In either case the gas, after being purified by washing with water, is stored in a copper bell or gasometer. Thence it is pumped along with water into copper or gun-metal vessels lined with pure tin, being made to dissolve in the water either by agitation or by other appliances. When the pressure inside these vessels reaches about 100 lb. per square inch, the water contains almost seven times its volume of gas, and is ready to be filled into bottles. The *bottling* is accomplished with great speed, an expert bottler being able to fill from thirty to fifty dozen of corked bottles per hour; while, when patent (ball-stoppered, screw-stoppered, &c.) bottles are used, from forty to seventy dozen may be filled. At first only corks were used for closing the bottles; but numerous patent bottles have been introduced, many of which depend on the internal pressure of the gas forcing a ball of glass, wood, or other material against a rubber ring placed in the neck, and thus sealing the bottle. The *siphon* is a glass bottle, fitted with a metal top, and furnished with a lever or handle, which enables a portion of the contents to be drawn off without difficulty. The head should be of the purest tin, to avoid contamination of the aerated water. Formerly there was risk of lead-poisoning by aerated waters, as they readily dissolve lead, but all manufacturers of any repute now make it a point to use no lead-piping whatever in their machinery, pure tin-pipe being alone admissible.

The better known kinds of aerated waters are: (1) *Potash and Soda waters*, which, when of full medicinal strength, contain fifteen grains of the bicarbonate of potash or soda in each bottle; usually, however, much less is put in, and the amount ranges from one to seven or ten grains; (2) *Aerated water*, which is frequently sold for soda-water, but is a simple solution of carbonic acid, and contains no admixture; (3) *Seltzer water* (better *Selters water*, being named from Selters, in Nassau, where natural mineral water of this composition is obtained), which contains the chlorides of sodium, calcium, and magnesium, along with phosphate and sulphate of sodium; (4) *Medicinal waters*, containing varying proportions of chemicals, as, for instance, lime, carbonate of iron, citrate of lithia, or bromide of potassium.

The temperance drinks, which include such favourites as lemonade, ginger-beer, ginger-ale, and some others, are all made by putting the requisite quantity of flavouring syrup into a bottle, and filling up with simple aerated water; and the varying qualities in the market correspond to the variety in the receipts from which they are made.

On the small scale, and for family use, carbonic acid water may be conveniently prepared in the apparatus known as the *gazogène* or *seltzogene*. It usually consists of two globes, one above the other, and connected by a tube. Powders of bicarbonate of soda and tartaric acid are then placed in the upper globe, and the apparatus is inclined till water from the lower globe enters by the tube, and fills the upper globe about one-third. The tartaric acid and bicarbonate of soda have no action on each other so long as they are dry; but whenever water is admitted, the tartaric acid combines with the soda and water to form tartrate of soda and water, and at the same time carbonic acid is given off, and descending the tube into the lower globe, dissolves in the water contained therein. A convenient arrangement also is that in which a small steel bulb containing liquefied carbonic acid is made to discharge its contents into a siphon containing plain or medicated water.

Many waters naturally aerated have important medicinal properties; see MINERAL WATERS, and Kirkby on *Artificial Mineral Waters* (1902). See also SEIDLITZ POWDERS.

Aerodrome, a name proposed by Langley, now superseded by AEROPLANE (Monoplane or Biplane, as the case may be). The word is now applied to a station or exercising-ground for aircraft, with hangars, workshops, &c. See BALLOONS AND AEROPLANES.

Aerodynamics is that branch of Hydrodynamics (q.v.) which treats of air and other gases in motion.

Aeroklinoscope is the name of an instrument invented by Buys-Ballot, and used in connection with weather-signals for exhibiting publicly the difference of barometric pressure at different observing stations. One form is a pole 30 feet high, turning on a pivot, and having on the top a horizontal arm capable of being inclined more or less. The system of working the arm is settled by agreement. See SIGNALLING.

Aerolites (Gr. *aēr*, 'air,' and *lithos*, 'stone'), a name given to stony or metallic bodies falling on the earth's surface from interplanetary space. See METEORS.

Aeronautics. See BALLOONS AND AEROPLANES.

Aerostatic Press. This is a machine used in extracting the colouring-matter from dye-woods and such like. A vessel is divided by a horizontal partition pierced with small holes. Upon this the substance containing the colour is laid, and a cover, also perforated, is placed upon it. The extracting liquid is then poured on the top, and the air being drawn from the under part of the vessel by a pump, the liquid is forced through the substance by the pressure of the atmosphere.

Aerostatics is that branch of Hydrostatics (q.v.) which treats of the equilibrium and pressure, &c. of air and gases.

Æschines, an Athenian orator, second only to Demosthenes, born 389 B.C. In the question of the attitude of Athens towards King Philip of Macedon, who was then pursuing his designs for the subjugation of the several Greek states, Demosthenes advocated the policy of opposing him before it was too late, while Æschines was the head of the peace-party. He was a member of more than one embassy sent by the Athenians to Philip; and Demosthenes accused him of receiving bribes from the Macedonian monarch, and of betraying the cause of Athens and of her allies. There is no proof that this was the case; and perhaps Æschines was deceived by the wily Philip into believing that no harm was meant to the liberties of Athens, and that peace was the best policy for his countrymen. The result justified the sagacious fears of Demosthenes, and condemned the selfish, isolating policy of Æschines. When it was proposed to reward Demosthenes with a golden crown for his patriotic exertions in defence of his country, Æschines indicted the proposer, Ctesiphon, for bringing forward an illegal proposition. Demosthenes replied in perhaps the greatest of his speeches, and Æschines being vanquished, and having thus incurred the penalty attached to an unfounded accusation, was obliged to retire from Athens. He finally established a school of eloquence in Rhodes, which enjoyed a high reputation. The story is told that once he read his great oration against Ctesiphon at Rhodes, and when some of his hearers expressed their wonder at its want of success, he replied, 'You would cease to be astonished if you had heard Demosthenes.' He died at Samos, 314 B.C. The oration against

Ctesiphon and two others are the only authentic productions of Æschines that have come down to us. They are found in editions of the Attic orators, as those of Bekker. Good editions of the three speeches alone are those by Franke (Leip. 1860) and Weidner (Berl. 1872). See Jebb's *Attic Orators* (2 vols. 1876-80).

Æschylus, the son of Euphorion, to us the father of Greek tragedy, was born at Eleusis, the town of the Mysteries, near Athens, in 525 B.C., and no doubt had his religious feeling stimulated by the solemn services which represented the deepest and purest elements of Greek religion. We know that he was initiated, by the fact that he was accused of divulging the divine secrets in one of his plays. The first attempts at tragedy had been made by Thespis, who is to us only a name; and there were older contemporaries of Æschylus, with whom he contended successfully, but who no doubt helped to perfect his education in poetry. He fought for Athens in the great Persian wars, and is reported to have been wounded at Marathon, where his brother fell. Pausanias tells us that in his epitaph he recalled these facts of his life, rather than his victories as a poet. The first of these latter was gained in 485 B.C., and from this time till the middle of the century he worked with all the energy and patience of a great genius at his art. He won thirteen first prizes in tragic competitions, and was exceedingly hurt at being defeated by Sophocles in 468 B.C. This may have induced him to leave Athens and go to Sicily, which he had already visited to bring out a play for the artistic tyrant Hiero. He produced there a new edition of his extant *Persæ*. His trial before the Areopagus on the charge of divulging the Mysteries is, however, also stated as a cause of his departure. His last great victory was won in 458 B.C., with the trilogy which we still possess, and three years later he died at Gela in Sicily, where his tomb was shown long after. The Athenians specially rewarded any impresario in after-days who brought out his plays afresh. There are a few fables current in addition to the above meagre facts, but they are not worth repeating here. Out of some sixty plays ascribed to him, we have only seven extant, on each of which we shall say a word.

The *Suppliants* is the earliest, at least in form (its date uncertain), for the chorus is still the principal feature, as we know it had been in the first attempts of Thespis. The plot, which is exceedingly simple, is based on the escape of the fifty daughters of Danaus from their suitors, the sons of Ægyptus, and their *supplications* to the king of Argos to protect them. There is very little character-drawing, save that of nationalities, the petulant and insolent Egyptians being contrasted with the honourable and somewhat democratic people of Argos, whither the suppliants have fled. Yet this simple subject gives the poet occasion for the loftiest utterances on Fate and Divine Providence, expressed in that tremendous diction which no other Greek poet ever equalled.

The *Persæ* is profoundly interesting, as giving us, in a tragedy, a piece of contemporary history, for the poet fought in the battle of Salamis, which he describes. But far from degrading his play into a mere panegyric of Athenian valour, the poet lays his scene far away at the Persian court, where the queen-mother Atossa is awaiting news of Xerxes' army. The ghost of Darius which appears is perhaps the most distinctive character.

The *Seven against Thebes* brings us to a more advanced stage of the poet's development. It is no longer the chorus but Eteocles, the patriotic king of the Cadmeans, who takes the leading part. The drawing of his character is clear and sharp, and Mr Verrall, in his edition of this play (1887),

has also shown with what delicate artifice the poet has brought his hero, by the insensible steps of a hideous fate, to meet his brother Polynices in fratricidal conflict. Both the narrative of the messenger who gives the details of the fight, and the choruses uttered by terrified maidens of the city, are full of life and beauty. The bringing in of the bodies, and the lament over them, form a sort of musical conclusion to the play.

The *Prometheus Bound* is the perfection of Æschylus' art, and shows us what his genius could do in *simple* tragedy, in the old plotless, motionless, surpriseless drama, made up of speeches and songs and nothing more. We now have three actors together on the stage, and the duties of the chorus, once so prominent, are becoming restricted to subordinate work. Prometheus, the heroic sufferer, sustains the whole interest of the play. He is driven with insult to the Caucasus. He soliloquises. He discourses with friendly nymphs and their cautious father, Oceanus. He condescends with the frantic Io, who passes by in her wanderings: he prophesies her future. Lastly, he bids defiance to Zeus, through his messenger Hermes, sent to coerce him into further prophecy, and disappears amid thunder and whirlwind. Almost every commentator has imagined that Æschylus had some deep theory in his mind, which he desired to illustrate by the play. But whether that theory was philosophical, or moral, or scientific, or political—whether he meant to symbolise the struggles of man against nature, or against passion, or against tyranny, or against theology—will never be determined.

We now come to the *Oresteia*, or three plays on the fortunes of Orestes, which is the latest and greatest work we have from Æschylus. These pieces, the *Agamemnon*, *Choephori*, and *Eumenides*, are the only extant specimens of what the Greeks called a trilogy, and show us how the older tragic poets combined three plays on a single subject.

The first of the series, the *Agamemnon*, is the longest play left us by the poet, as perhaps the greatest Greek play of all that have survived. With a perfectly simple plot, there is splendid and consistent drawing of character, deep philosophy in the choral songs, and a certain gloomy grandeur which makes it unique. The central point of interest to the reader is the scene between Cassandra and the chorus, when she tries to make plain to them the horrid murder of the king, which she foresees as imminent. Agamemnon is drawn as in the *Iliad*, a great king but a weak man, while Clytæmnestra is the leading spirit of the piece. Even in the collateral quality of picturesqueness, this masterpiece is above almost all its rivals.

The *Choephori*, a shorter and less striking play, but not without the same grandeur and the same gloom, gives us the return of Orestes from exile, and his murder of Clytæmnestra, in accordance with both the command of the oracle and the sentiments of the Greek mind.

In the *Eumenides*, we find the necessary results of the previous tragedy. Though Orestes has obeyed one great moral law, avenging the blood of his father, he has violated another no less sacred in taking the life of his mother, whose Furies (*Eumenides*) persecute him with ceaseless pursuit.

There are a large number of short fragments preserved in quotations, but none of sufficient importance to detain us here. The genius of Æschylus is quite peculiar in Greek literature, and he has no equal. There is something oriental in his boldness, his uncouth yet expressive compounds, his daring, piled-up metaphors. But what distinguishes him still more from great contemporaries like Pindar, or great successors like Sophocles, is the grandeur of his

conceptions in theology, in the providential ruling of the world, the inheritance of sin, the conflict of rude with purer religion.

There are texts by Weeklin (1885-93), Paley (4th ed. 1879), Sidgwick (1900), Wilamowitz-Möllendorf (1914); single plays by Sidgwick, Verrall, Prickard, Tucker, Weil, Mills, and others; translations in prose by Paley (1871) and Headlam (1904-10), and in verse by Potter, Blackie, Plumptre, Miss Swanwick, Lewis Campbell, Way (1906-9), and of one or more plays by R. Browning, FitzGerald, Morshead, Mrs Browning, Bevan, and Warr (1900).

Æsculapius (Gr. *Asklēpios*) appears in Homer as the 'blameless physician,' of human origin; in the later legends, he has become the god of the healing art. The most common account makes him the son of Apollo and Coronis. He was brought up by Chiron, and instructed in the healing art, in which he soon surpassed his teacher, and succeeded so far as to restore the dead to life. Pluto, afraid that his realm would get no new inhabitants, therefore complained to Zeus, who slew the physician by a thunderbolt. After this he was raised to the rank of the gods by the gratitude of mankind, and was especially worshipped at Epidaurus, on the coast of Laconia. Here oriental elements, especially serpent-worship, seem to have been mingled with his rites and ceremonies. From Epidaurus the worship of the healing god extended itself over the whole of Greece, and even to Rome. According to Homer, Æsculapius left two sons, Machaon and Podalirius, who, as physicians, attended the Greek army. From them the race of the Asclepiades descended. Hygieia, Panacea, and Ægle are represented as his daughters. The temples of Æsculapius usually stood outside of the cities in healthy situations, on hillsides, and near fountains. Patients that were cured of their ailments offered a cock or a goat to the god, and hung up a tablet in his temple, recording the name, the disease, and the manner of cure. Many of those votive tablets are still extant. The statue of the god at Epidaurus, formed of gold and ivory by Thrasymedes, represented Æsculapius as seated on a throne, and holding in one hand a staff with a snake coiled round it, the other hand resting on the head of a snake; a dog, as emblem of watchfulness, at the foot of the deity. Praxiteles and other sculptors represented the god as an ideal of manly beauty, closely resembling Zeus; with hair thrown up from the brow, and falling in curls on each side. The upper part of the body was naked, and the lower was covered by a mantle falling in folds from the shoulders. He had sometimes a laurel wreath on his head, and a cock or owl at his feet; or was attended by a dwarf-figure named Thelesphorus.—ASCLEPIADES, the followers of Æsculapius, who inherited and kept the secrets of the healing art; or, assuming that Æsculapius was merely a divine symbol, the Asclepiades must be regarded as a medical, priestly caste who preserved as mysteries the doctrines of medicine. The members of the caste, or medical order, were bound by an oath—the *Hippocratis jururandum*—not to divulge the secrets of their profession. Hippocrates is said to have descended from the Asclepiades of Cos, who traced their descent, on the mother's side, from Hercules.

Æsir, a race of gods in the Scandinavian Mythology (q.v.).

Æsop, the famous Greek fabulist, who lived in the later half of the 6th century B.C. He is supposed to have been originally a native of Phrygia and a slave, but to have been afterwards made free. He then visited the court of Croesus, and gained his confidence to such an extent that he was sent on several missions, in one of which, to Delphi, he was thrown over a precipice by the priests, infuriated at his witty blasphemies. The traditions of his ugliness and his buffoonery may

be dismissed. We know from Aristophanes that fables bearing the name of Æsop were popular at his time, and indeed we find that his name became in Greek literature a peg on which to hang anything in this form. The fables connected with his name were long transmitted through oral tradition. Socrates turned such of them as he could remember into verse during his imprisonment, and the same was done by Demetrius Phalereus. The only Greek version, however, of which any entire fables remain, and which, as shown by Bentley, has furnished materials to subsequent collections, is that of Babrius (q.v.). Later investigations have given to these ancient fables a still more venerable antiquity, in tracing some of them to the Birth-stories of Buddha; see JATAKA, BEAST-FABLES, FABLE, and Joseph Jacobs's introduction to his edition of the fables (1894). Some were known to the ancient Egyptians. For the *Ysopet*, see MARIE DE FRANCE.

Æsopus, CLAUDIUS, Roman actor, a contemporary and friend of Cicero, was as eminent in tragedy as Roscius was in comedy.

Æsthesiometer, an apparatus developed in connection with modern anthropometric and quantitative psychological research, and designed to determine the degree of tactile sensibility in the human skin and the various parts of the same. The simplest type resembles a pair of compasses with the points somewhat blunted. The two points are pressed on the skin, and the distance between them required to allow of their being felt or distinguished as two points and not as one, shown on a scale, indicates the degree of sensitiveness at that part of the body. Notoriously the distance has to be much greater on the back or on the thighs than, say, on the hands, fingers, or tongue, where sensitiveness is most acute.

Æsthetics might etymologically (as concerning *asthēta*, things perceptible by the senses) be expected to mean the department of psychology concerned with sense-perception. But in modern philosophy it has long come to mean the science that deals with the principles of beauty or of taste; inasmuch that in Britain in the last quarter of the 19th century *asthete* came simply to mean a person who affected an exaggerated or even fatuously sentimental love of beauty, to the exclusion of practical considerations, true proportions, or art values. Æstheticism in this sense attached a fantastic significance to bric-à-brac, old china, dadas, old gold curtains, sunflowers, an 'intense' manner, the ornamental and decorative generally; and extravagant aspects or tendencies provided a rich fund of material for railery in Du Maurier's *Punch* cartoons and Gilbert and Sullivan's *Patience* (1881).

Æsthetica was first used for the principles of taste and of art by the Wolfian philosopher, Baumgarten; and though Kant, keeping nearer the meaning of the original Greek word, dealt in his *Transcendental Æsthetic* with the conditions of sensuous perception, Baumgarten's usage, as being convenient, became popular, and was established in Britain about 1830.

The name of Plato is bound up with the history of speculation on the Beautiful, which he never wholly separated from the Good. His position is far from precise, but it may be said that for him the beauty of finite things arises out of their participation in the eternal and ideal archetypes which constitute the keynote of all his speculations. Aristotle is more precise than his master, and left a body of valuable and still valid canons of criticism, especially for poetry. An Aristotelian dictum is, that the beautiful is that which is neither too large nor too small, a mean between extremes.

Baumgarten above mentioned (*circa* 1750) is the father of æsthetics as a well-defined system. According to him and his followers, sense is the lower intellectual power, understanding and reason the higher. As the true and the good are apprehended by the latter, the beautiful is grasped by the former; and æsthetics is a humbler stage of the intellectual energies.

Winckelmann did much to further æsthetic criticism by his examination of the principles of Greek sculpture; Lessing still more, by his attempt to distinguish, in his *Laocoon*, the province of poetry from that of painting and sculpture, and by excluding from the legitimate sphere of plastic art the representation of the repulsive and disgusting. Schiller was not merely a great poet, but a suggestive critic; and one of his trenchant maxims was that 'the annihilation or superseding of the *matter* by the *form* is the true art-secret of the master-artist.' The influence of Goethe by means of his *Wilhelm Meister* and other works, has probably influenced the thought of Europe still more.

Kant's *Critique of Judgment* deals with the *a priori* principles of emotion, of pleasure and pain, as intermediate between knowledge and volition, the judgment being æsthetical or teleological respectively; while the beautiful is analysed with reference to the four well-known categories of his system. Fichte and Schelling both included æsthetics in their schemes of philosophy; but the work of Hegel in this department attracted much more interest, and was for a time of paramount influence in Germany. With him, the beautiful is the absolute ideal realising itself; nothing is truly beautiful except this; nothing, therefore, which exists in concrete form can be so termed. Out of the sphere of the pure reason we have only an eternal aspiration. In the finite mind, the absolute ideal is always striving to realise itself, but never completely succeeds; there is only a ceaseless approximation. Beauty, whether of nature or history, is rare, accidental, fugitive, and tarnished by intermixture with the not-beautiful. The beautiful first passes into self-recognition in the dawn of human intelligence, and its conscious realisation of itself increases in proportion to the culture of the race or the individual. The highest finite realisation of it is Art; for though the form of art be material, it is matter shaped according to an idea. The artist looks on the form simply as the objective embodiment of the idea. Form, though springing out of matter, is thus a deliverance from matter, and the particular arts may consequently be regarded as the gradual working of the mind out of materialism. The formative arts—Architecture, Sculpture, Painting—are silent, heavy, still partly material. Music is an advance on these, and breathes in a higher region; the materialism of Sound becomes all but ideal. Poetry is a further advance. It is the pathway of the intellect to pure thought.

Herbart and the Realists, including Zimmermann, directly opposed the Hegelian theory. For them, æsthetics is that branch of philosophy which deals with the forms by which any subject of thought provokes pleasure or the reverse, whether it be a representation of a reality or a pure invention of the imagination; a picture does not gain in *beauty* by reality, though it may gain in *truth*. Vischer and Carrière, Schopenhauer and Kirchmann, Fehner and Lotze, amongst German systematists, have all copiously dealt with æsthetics.

In France, Diderot and Père Buffier propounded theories of beauty. The founder of the Eclectic School of Philosophy, Victor Cousin, eloquently expounded the Platonic view.

In Britain, the first publication on this subject of

any consequence—if we except Lord Shaftesbury's *Characteristics*, in which there is set forth a 'rapturous Platonic doctrine'—was Hutcheson's *Inquiry* (1725). In this work, the existence of an 'internal sense,' through which we either obtain a perception of the beautiful, or are made in some way conscious of its presence, was maintained.

Burke, in his famous *Treatise on the Sublime and the Beautiful* (1756), relies mainly on physiological considerations. Amongst the elements of beauty are smallness, smoothness, variety of outline, delicacy, brightness and softness of colour. 'All objects appear beautiful which have the power of producing a peculiar relaxation of our nerves and fibres.'

Sir Joshua Reynolds, borrowing from Père Buffier, treated beauty as the mean between two extremes. Hogarth's more ingenious and acute *Analysis of Beauty* emphasises fitness, variety, symmetry, intricacy with simplicity and distinctness, and size.

Alison's *Essays on the Nature and Principles of Taste* (1790) propounded the theory of Association. Jeffrey, in his famous essay, substantially adopts and expounds Alison's views. According to Jeffrey, 'these emotions (that is, those excited by the contemplation of certain objects) are not original emotions, nor produced directly by any qualities in the objects which excite them; but are reflections or images of the more radical and familiar emotions to which we have already alluded, and are occasioned not by any inherent virtue in the objects before us, but by the accidents, if we may so express ourselves, by which these may have been enabled to suggest or recall to us our own past sensations or sympathies.' He explicitly denies that there is any independent or intrinsic beauty in form.

Sir William Hamilton distinguishes beauty into Absolute and Relative. 'In the former case,' he says, 'it is not necessary to have a notion of what the object ought to be before we pronounce it beautiful or not; in the latter case, such a previous notion is required.' In the case of free or absolute beauty, 'both the imagination and the understanding find occupation; and the pleasure we experience from such an object is in proportion as it affords to these faculties the opportunity of exerting fully and freely their respective energies. The beautiful is that whose form occupies the imagination and the understanding in a free, full, and consequently an agreeable activity.'

Ruskin did a great deal to awaken and extend the appreciation and enjoyment of art in Britain, and in several of his works discusses æsthetic theories; especially in *Modern Painters* he has attempted a systematic exposition of our ideas of beauty. Beauty is typical or vital, the former falling under the heads of infinity, unity, repose, symmetry, purity, moderation—all typical of divine attributes; while vital beauty is relative or generic. Ruskin's position is that of an extreme spiritualist, and takes no account of the value of association at all.

Bain, a prominent representative of the empirical school, has largely treated of æsthetics in his work on *The Emotions and the Will*, and has made an elaborate analysis of the elements in our perception and enjoyment of beauty. Herbert Spencer has endeavoured to establish an original theory of the origin of our pleasure in beauty and art, based on the doctrine of evolution as developed by him.

Others who have contributed to the discussion of the problem are Jean Paul Richter in Germany; in France, Jouffroy and Taine; and in Britain, Reid, Addison, Dugald Stewart, and Lord Kames. Schasler, Zimmermann, Lotze, and Carrière have written in Germany works on the history of

æsthetics; in France, Lévêque; and in his *Æsthetics* (trans. 1909) Benedetto Croce has made an important contribution to the science. American writers are Jarves, Bascom, Kedney, and Torrey. See ART, ASSOCIATION OF IDEAS, EMOTION; Hegel's *Phil. of Fine Art* (transl. by Bosanquet, 1887); Lotze's *Outlines of Æsthetics* (trans. by Ladd, 1887), and Bosanquet's *History of Æsthetics* (1892).

Æstivation (Lat. *æstivus*, 'belonging to summer'), or PRÆFLORATION, a term employed to denote the manner in which the sepals and petals are disposed in the flower-bud. The different modes of æstivation are different solutions of the problem of packing the floral envelopes into smallest bulk, and some of the arrangements are apparently the results of twisting. The æstivation of the sepals is often different from that of the petals. The

Various forms of Æstivation regarded as modification of the quincuncial or valvate type:

a, quincuncial; b, half-imbriate; c, imbricate; d, contorted; e, vexillary; f, cochleate; h, valvate; g, valvate unduplicate; i, valvate reduplicate.

precise arrangement in a flower can be readily seen by making a cross section of the bud, but some of the commonest forms may be noted. When the parts meet but do not overlap, the arrangement is called *valvate*; but if the adjacent margins are turned inwards or outwards, the terms *unduplicate* and *reduplicate* are used. In many cases, each part overlaps its neighbour at one margin, and is still overlapped at the other, and to this the term *contorted* is applied. In *imbricate* æstivation, the parts successively overlap from the first, which is wholly external, to the last, which is wholly internal. The term *quincuncial* is applied to an exceedingly common arrangement in which two parts are external, two internal, while the fifth overlaps one of the internal parts and is overlapped by one of the external. In the papilionaceous corolla (see LEGUMINOSÆ), the standard overlaps the wings, while they overlap the keel. In the poppy, the petals are much crumpled in the bud.

Ætheling. See ATHELING.

Æther. See ETHER.

Æthroscope is an instrument for measuring the minute variations of temperature due to the condition of the sky, and consists of a differential Thermometer (q.v.) whose bulbs are both within a cup-shaped mirror, one being in the focus of the mirror.

Ætiology, or ETIOLOGY (Gr. *aitia*, 'cause,' and *logia*, 'discourse'), the science or philosophy of causes and causation, especially (1) the department of biology, which seeks to give a scientific account of the factors operative in the evolution of organisms (see DARWINIAN THEORY, and EVOLUTION); (2) the branch of medicine which investigates the causes and origin of diseases.

Ætius, a great Roman general, born in Moesia towards the end of the 4th century A.D. He was for a time a hostage amongst the Huns. He led an army of Huns to the support of the usurping

Emperor John; and by help of the Huns compelled the empress-mother Placidia to advance himself at the expense of his rival Bonifacius. In 433 he became patrician, consul, and general-in-chief; and as such maintained the empire against the barbarians for twenty years, defeating West Goths, Burgundians, rebellious Gauls, and Franks. But his 'crowning victory' was that at Châlons over Attila (q.v.) in 451. In 454 the Emperor Valentinian III. (q.v.), jealous of his greatness, stabbed him to death with his own hand.

Ætna. See ETNA.

Ætolia, a district of ancient Greece, lying on the N. coast of the Gulf of Corinth. It was divided from Acarnania by the river *Achelous*, and on the N. touched Thessaly. In later times, these boundaries were considerably extended to the N. and E. The country had few cities; was, except on the coast, generally wild and barren. Here, according to the legend, Meleager slew the Calydonian boar. The Ætolians make a great figure in the heroic age of Greece; but at the time of the Peloponnesian war, they were rude and barbarous. The Ætolian Confederacy, first called into existence about 323 B.C., became an important rival to the Achæan League (see ACHAIA). Their assembly was styled the *Panætolicon*. They sided with the Romans against the Achæan League, but afterwards aided Antiochus III. against the Romans, and were subjugated by the Romans in 189 B.C., though not formally included in a Roman province till 146. Along with Acarnania, Ætolia now forms a department of the modern kingdom of Greece, with a united area of over 3000 sq. m. The mountains in the NE. are offsets of the Pindus chain, and slope steeply on the SW. down to the central plains. The chief towns are Missolonghi and Lepanto.

Affidavit (from the perfect tense of a barbarous Latin verb, *affido*—e.g. *A.B. affidavit*, 'A.B. hath sworn'), an oath in writing, or a written declaration made before a magistrate, or other person legally authorised to administer an oath, the truth of which is confirmed either by an oath sworn, or a solemn affirmation emitted in terms of the Oaths Act, 1888 (51 and 52 Vict. chap. 46), and the other statutes referred to under AFFIRMATION. Where evidence is required in England to be laid before a court, it is frequently given by affidavit, and not by oral examination. This is almost invariably the case on interlocutory applications before trial—e.g. for discovery of documents. Many isolated facts are proved by affidavit—e.g. service of proceedings; the condition of a will with alterations of which probate is asked, &c. Where the whole evidence is given by affidavit, a practice discouraged in England since the union of the Common Law and Equity Courts, the plaintiff first files his affidavits in chief, and these are replied to by the defendant's affidavits. The affidavit consists of title, body or statement, and jurat. An affidavit ought to set forth the matter of fact only, and not to declare the merits of the cause, of which the court is to judge. The name, place of abode, and designation of the party making the affidavit are written at length, and he signs it at the foot. When the paper is shown to him, he is required to swear or affirm that its contents are true, and that the name and handwriting are his. Affidavits in all the English courts must be taken and expressed in the first person of the deponent, and are divided into paragraphs numbered consecutively. The *Jurat* specifies the officer before whom, the place where, and the time when it was sworn, and this is signed by the officer or magistrate. When an affidavit is sworn in open court, that circumstance is mentioned, and no officer is named. Under the

Bankruptcy Act, 1883, the expression 'affidavit' includes statutory declarations, affirmations, and attestations on honour. In Scotland voluntary affidavits are not generally received as evidence, because they are *ex parte* statements, no opportunity being afforded for cross-examination. But in certain matters affidavits are required by statute—e.g. under the Bankruptcy Acts, the Confirmation of Executors Act, &c. An affidavit is sometimes required also at common law, as in applications for warrants in *meditatione fugæ*, and, as in England, on various interlocutory applications—e.g. for postponement of trial, or for commission to examine before trial sick and aged witnesses. Apart from judicial proceedings, affidavits are required by imperial statutes in a great many circumstances which make a deliberate and formal statement, under the sanctions of perjury, desirable in the public interest. Under English law affidavits may be sworn before a person authorised to administer oaths in the High Court, or before any registrar of a bankruptcy court, or before a justice of the peace. In the United States the law is very similar. The affidavit of parties to a cause is received upon incidental questions addressed to the court, and auxiliary matters not affecting the issue. An affidavit made solely on information or belief is not sufficient for the arrest of any person charged with an offence against the laws of the United States.

Affiliation, or **FILATION**, is the name given to an action brought in the sheriff courts in Scotland by the mother of a bastard to recover aliment from the putative father. It is the equivalent of the proceeding for a Bastardy Order before the justices in England. The old common-law rules as to the evidence required to prove paternity in such cases have been modified, since the Evidence Act of 1853 made the parties to the action competent witnesses. The rates of aliment allowed against the father vary in different districts in Scotland; in Glasgow it is £8 per annum until the age of 7 or 10, or some other fixed age, when the mother's right of custody expires, and the father may make his arrangements for the child's maintenance. A debt of this nature may still be enforced by imprisonment. There are risks of fraud and extortion in affiliation proceedings, and it is settled in Scotland, and has been expressly enacted in England, that to establish paternity there must be evidence corroborating the statement of the pursuer.

Affinity (Lat. *affinitas*), the relationship created by marriage between the husband and the blood-relations of the wife, and between the wife and the blood-relations of the husband. The relatives of the wife stand to the husband in the same degree of affinity in which they stand to the wife by blood or consanguinity, and *vice versa*. But between the relatives of the two parties by affinity there is no affinity. Thus there is no affinity between the husband's brother and the wife's sister, and by our law there is no impediment to their marriage. The question as to whether those who are related by affinity stand in all respects in the same position as regards marriage with those connected by blood is one on which much difference of opinion at present prevails. The general rule of English and Scots law is that intermarriage is prohibited between persons within the third degree of consanguinity, and also intermarriage with the wife or husband of any one so related. But the Deceased Wife's Sister's Marriage Act, 1907, legalises the marriage with a deceased wife's sister or half-sister as a civil contract. The act does not legalise a marriage with the sister of a divorced wife. The Deceased Brother's Widow's Marriage Act, 1921, legalises marriage with a deceased husband's brother.

In the United States the law is substantially as in England: a person cannot by legal succession receive an inheritance from a relation by affinity. See **CONSANGUINITY**, **DECEASED WIFE'S SISTER**, **MARRIAGE**; for the anthropological aspect, **FAMILY**, **KIN**.—For Chemical Affinity, see under that head.

Affirmation is a solemn declaration now admitted in lieu of an Oath (q.v.) in all cases where a witness objects to being sworn, and states, as the ground of such objection, either that he has no religious belief or that the taking of an oath is contrary to his religious belief. The form of affirmation prescribed by the Oaths Act, 1888, is: 'I, A. B., do solemnly, sincerely, and truly declare and affirm.' By this act the profession of allegiance to the crown exacted from members of parliament may also now be made by affirmation. The earlier statutes which were passed from time to time giving relief to Quakers and others who had conscientious scruples against taking an oath have, in view of the general relief given by this act, been repealed. Under the Perjury Act, 1911, the penalties of perjury attach to the wilful making of a statement known to be false, equally whether the statement was made on oath or on affirmation. In the case of certain offences against children, a child in England is now permitted by recent statutes to give evidence without being sworn if it understands the duty of speaking the truth. In Scotland the evidence of children too young to be sworn is admissible in the discretion of the judge.

Afforestation. See **FORESTRY**.

Affre, **DENIS AUGUSTE**, was born 27th September 1793, and in 1840, on account of his prudent and temperate character, was made Archbishop of Paris by the government of Louis Philippe. Though not yielding a blind submission to all the measures of that government, he abstained from offensive opposition; and when in 1848 a republic was proclaimed, he kept aloof from political strife, but displayed earnest care for the public welfare. During the June insurrection he climbed on a barricade in the Place de la Bastille, carrying a green bough in his hand, as a messenger of peace; but he had scarcely uttered a few words when the firing recommenced, and he fell mortally wounded, to die next day, June 27. He was the author of several theological writings, and of a work on Egyptian hieroglyphics. It should be added that his death was due to a casual bullet, not aimed at him at all, and that the accident was sincerely regretted by the leading revolutionists.

Affrontée, in Heraldry, fronting the beholder, as the lion sejant affrontée, the crest of Scotland.

Afghanistan is the country lying to the north-west of India. Its boundaries are, on the north, the Oxus or Amu Daria, from its source in Lake Victoria or Sir-i-Kul to Khoja Saleh, and thence a line drawn across the Turkoman desert south-westward to the Murghab, passing south of Panjdeh, and touching the Hari-Rud at Zulfikar. This line has been demarcated in accordance with the London protocol of 1885 and the St Petersburg treaty of 1887. On the north-east Afghanistan is bordered by a mountainous region, inhabited by tribes of various nationalities, but for the most part speaking Afghan dialects, and settled in the fertile but almost inaccessible valleys of the Upper Indus and its tributaries. On the east the frontier has been affected by the agreements of 1893-1919. On the south a line passing north and west of Quetta, and then running westwards, following approximately the 30th parallel of N. lat., divides Afghanistan from Baluchistan; while on the west the meridian of 61° E. long. would approximately define the boundary with Persia.

Within these limits, Afghanistan extends 400 miles from north to south, and 600 miles from east to west, and contains an area which may be roughly estimated at 240,000 sq. m., or about twice the size of Great Britain and Ireland. This includes Badakhshan and Wakhan in the north-east, and Afghan Turkestan in the north, comprising the Uzbek States of Balkh, Kundúz, Maimana, Shibarghan, Khulm, Akchá, and Andkhói, owning allegiance and paying tribute to the Amir. Afghanistan may be divided into the three great river-basins of the Oxus, the Indus, and the Helmand. (1) Oxus basin. The northern slopes of the Hindu Kush are drained by a number of rivers flowing northwards towards the Oxus;

only two, however—the Kokcha and Kunduz—reaching that river, while the remainder are either absorbed in irrigation, or disappear in the sands. The westernmost of the series—the Murghab and Hari-Rud—are of great importance, owing to the geographical position and fertility of their valleys, affording two lines of approach to Herat from the north. (2) The Indus basin includes the great basin of the Kabul itself and its tributaries, draining the southern slopes of the Hindu Kush and the northern valleys of the Safed-Koh; the basin of the Kuram, commanding a well-known approach to Kabul from the Indian frontier at Thal; and the streams issuing from the Waziri hills and Suliman range. (3) The Helmand, with its three great

Berthelmeier, 1897

tributaries, the Argandab, Tarnak, and Arghistan, drains all South-western Afghanistan. Afghanistan is for the most part an arid, mountainous country, and cultivation is only met with in some of its valleys.

According to Holdich, the principal mountain systems of Afghanistan are the Hindu Kush, with its westerly continuations, the Koh-i-Baba, Paghman, Safed-Koh, and Siah-Koh. The Hindu Kush takes its rise in the north-east, where it abuts on the north-western end of the Himalayas in a group of magnificent peaks, rising to a height of 23,000 feet above the sea. Hence it extends in a south-westerly direction to the Khawak Pass as a single range of great height. Farther west it diminishes in altitude, and divides into a system of parallel chains, with high plateaus and valleys between them. The Safed-Koh, not to be confounded with the range of the same name in North-western Afghanistan, divides the Kabul from the Kuram, and has no geographical connection with the Hindu Kush, while the Suliman hills are now in-

cluded in India, not in Afghanistan. The climate of Afghanistan is as diversified as its physical configuration. At Ghazni (7279 feet) the winter is extremely rigorous, and for several months the inhabitants are snowed up in their houses. At Kabul (5600 feet) the cold is severe for two or three months, but the summers are temperate. At Kandahar the winters are milder, but the heat in summer is intense (110° F. in the shade). The climate of Seistan, in the south-west of Afghanistan, is hot and trying; while that of Herat, in the north-west, is temperate; though here, as in other parts of Afghanistan, violent north-westerly winds and dust-storms are frequent.

Fevers, intermittent and remittent, and diseases of the eye, are among the most common complaints of the Afghans. The population of Afghanistan is composed of a variety of nationalities, and is estimated at about 6,400,000. The Afghans proper, or Pathans, number about 3,000,000, and are divided into tribes or clans—Duránis, Ghilzáis, Yúsufzáis, and others. The

Duránis are the dominant tribe; the Ghilzáis, the strongest and most warlike; the Yúsufzáis, the most turbulent. Of the non-Afghans, the Tajiks are probably the most numerous, and are the agricultural and industrious portion of the population; the Hindkis and Játs chiefly live in the towns, and are traders; the Kizilbashs are Turko-Persians, and form the more educated and superior class; while the Hazáras, a race of Mongol origin, in the mountainous districts on the north-west of Afghanistan proper, are nomads. The Afghans claim descent from King Saul, and call themselves 'Bani Israel;' but though their features are of a Jewish type, and some of their customs have a curious analogy to those of the Jews, their language—the Pakhtu or Pushtu—has no affinity with the Semitic tongue, but rather belongs to the Aryan family. In religion they are Sunni-Mohammedans. In character they are proud, vain, cruel, perfidious, extremely avaricious, revengeful, selfish, merciless, and idle. 'Nothing is finer than their physique, or worse than their morale,' says an intelligent observer.

The Afghans do not as a rule inhabit towns, except in the case of those attached to the court and heads of tribes. The townsmen are mostly Hindkis and other non-Afghan races, who practise various trades and handicrafts considered derogatory by men of rank. The houses or castles in the country are all inclosed by high walls, and contain three or four different courts, laid out in gardens, with ponds and fountains, much the same as in Persia and Turkestan. The principal towns are Kabul (population 140,000), the seat of government and centre of a fertile district; Ghazni, a strong fortress; Kandahar, the chief city of Southern Afghanistan, with 30,000 inhabitants; and Herat, formerly considered the key of India. Among towns of secondary importance are Charikar, Istalif, 20 miles NNW. of Kabul, and Farah in Seistan.

Among the natural productions of Afghanistan is the plant yielding the asafetida. The castor-oil plant is everywhere common, and good tobacco is grown in the district of Kandahar. Aitchison says that the cultivated area round Herat produces magnificent crops of wheat, barley, cotton, grapes, melons, and the mulberry-tree; the production being only limited by the amount of labour procurable. Surrounding the villages, and in orchards, the ash, elm, apricot, apple, plum, quince, peach, and pomegranate are cultivated; the sanjit (*Elaeagnus orientalis*), yielding an edible fruit, and the zizyphus are indigenous. In special localities are forests of pistachio, its leaves being used in dyeing. The general appearance of the country during winter is barren and arid in the extreme, owing to the absence of trees and woody shrubs; but in spring a mass of vegetation springs up, giving a grand colouring to the landscape. The industrial products are silk, chiefly for domestic use, and carpets, those of Herat being of admirable quality. The manufacture of *postins*, or sheepskins, is one of the most important of the industrial occupations of the people, and of late years the trade in this article has greatly increased. Afghanistan is crossed by several trade-routes leading to India on the one side, and to Persia and Turkestan on the other; merchandise, however, is all transported on camel or pony back. Commerce suffers much from frequent wars and bad government. There is, however, some export of Afghan productions, particularly carpets to India; and Indian textile fabrics meet with a ready sale in Afghanistan.

History.—Afghanistan as an independent state dates only from the middle of the 18th century. For two centuries before, Herat and Kandahar had been in the possession of Persia; while

Kabul was included in the Mogul empire of Delhi. Upon the death of Nadir Shah in 1747, Ahmed Shah Duráni subjugated the different provinces, and when he died in 1773, left an empire to his son, Timur Shah, extending to the sea of Oman on the south, and on the east to the mountains of Tibet, the Sutlej, and the Indus. Timur Shah reigned twenty years, and dying in 1793, left thirty-six children, of whom twenty-three were sons. The rivalries and jealousies among these princes or sirdars, their attempts to concentrate absolute power in their own hands, their turbulence, cruelty, and treachery, kept Afghanistan in a constant state of warfare, and led to the interference, first of Persia, and then of the British. In 1809 Mount Stuart Elphinstone was sent as ambassador to Kabul, and concluded a treaty with Shah Shuja, son of Timur Shah, at Peshawar. Shah Shuja soon afterwards abdicated, and his brother, Mahmud Shah, took possession of the throne. His vizier, Futteh Khan, restored prosperity to Afghanistan for a while, but was blinded and afterwards murdered. His death was avenged by his brothers, the ablest of whom, Dost Mohammed, made himself master of Kabul in 1826.

In 1834 Shah Shuja made an effort to recover his throne, and entered Afghanistan with an army of twenty thousand Afghans and Hindustanis, but was defeated by Dost Mohammed. The siege of Herat by the Persians in 1837, when it was successfully defended mainly through the exertions of Lieutenant Eldred Pottinger, and Dost Mohammed's signal victory over the Sikhs, attracted the serious attention of the British government. Lord Auckland, then governor-general, declared war against Afghanistan in 1838, on the grounds that Dost Mohammed had unlawfully attacked the British ally, Runjit Singh; that the military operations of the Afghans had betrayed a hostile purpose towards India, and that Shah Shuja, as the rightful heir to the Afghan throne, had placed himself under British protection. It was designed to establish a friendly power in Afghanistan, which should form the first line of defence against the threatened advance of Russia on India. In pursuance of this policy, on the 16th January 1839, an army of 21,000 men, under the command of Lieutenant-general Sir John Keane, crossed the Indus, advanced without opposition through the Bolan Pass, and took possession of Kandahar. Ghazni was taken after some hard fighting, and on the 7th August, the Anglo-Indian army entered Kabul, where Shah Shuja was proclaimed Ameer. Dost Mohammed, deserted by his forces, retired beyond the Hindu Kush, and the conquest was regarded as complete. Sir William Macnaghten and Sir Alexander Burnes were established at Kabul as British political agents; and a body of Anglo-Indian troops was stationed there under General Elphinstone.

Events, however, soon showed that the British had altogether mistaken the character of the Afghans. Though Dost Mohammed had surrendered, his son Akbar Khan was actively engaged in a conspiracy, and on the 2d November 1841 an insurrection, caused, it is said, by the reduction of subsidies to the Afghan sirdars, broke out at Kabul. Burnes and his brother were hacked to pieces with Afghan knives, Macnaghten was treacherously shot seven weeks later at a conference with the Afghan sirdars, several British officers were slain, and the Anglo-Indian army, after being besieged in cantonments for sixty-five days, capitulated. It was then agreed that they should leave the country, and that Akbar Khan and his confederates should make arrangements for their retreat, and provide an escort. Depending on these promises, the British troops left Kabul on the 6th

January 1842, to return to India; but neither escort nor provisions were supplied, and the severity of the season increased the misery of the retreat. The fanatical tribes of the district harassed them on all sides, and out of 16,500, of whom 12,500 were camp-followers, only one man (Dr Brydon) escaped to carry the dismal tidings to General Sale at Jelalabad. To retrieve this disaster, General Pollock, in September 1842, advanced on Kabul, routed Akbar Khan, and having inflicted punishment on the Afghans, and rescued the English officers and ladies who had surrendered themselves as prisoners, led his army back to India.

Henceforward the policy of the new governor-general, Lord Ellenborough, was to be one of non-interference in the affairs of Afghanistan, and it was hoped that the Afghans would keep the peace. Soon afterwards, however, forming an alliance with the Sikhs, they assisted them in their war against the British, till a crushing defeat was inflicted on their combined forces by Lord Gough, at the battle of Guzerat, on the 21st February 1849, and Dost Mohammed fled across the Indus. On the 30th March 1855, he concluded a treaty with the British, and in 1863, soon after the capture of Herat, which he had besieged for ten months, he died, and was succeeded by Shere Ali Khan, one of his younger sons. At first, the choice was acquiesced in by the other brothers, but disagreements soon arose, which for many years kept Afghanistan in a state of anarchy, and at one time the fortunes of the Amir Shere Ali Khan were at a low ebb. The loss of a favourite son at the battle of Kajbáz (on the 6th June 1865) affected him so seriously that he ceased to interest himself in public affairs, and remained at Kandahar, while his rebellious half-brothers, Mohammed Afzul Khan, and Mohammed Azim Khan, with Abdul Rahman Khan, the son of the former, were gaining repeated successes, and alienating the country from his rule. The capture of Kabul at length aroused him to action. Taking the command of his forces in person, he led them against the entrenched position of the enemy; but notwithstanding the impetuosity of the assault, and his personal gallantry, he was defeated, and fled with a small following towards Ghazni and Kandahar. Other attempts to restore his fallen fortunes were equally unsuccessful, and it was not till 1868 that he at length regained possession of Kabul. In that year he received assistance from the viceroy of India, Sir John Lawrence, to secure the position for which he had fought so hard. The next viceroy, Lord Mayo, met the Amir in state at Ambála in March 1869. At this meeting it was explained to him that Her Majesty's government had no desire to interfere with the affairs of Afghanistan, except to check civil war, and by so doing, to secure the peace and prosperity of the country. This intimation was accompanied by another large present.

In 1870 the Amir's eldest son, Yákúb Khan, who had shown great ability as governor of Herat, and had, on many occasions, given his father valuable assistance, broke into open rebellion against him. In 1873 Abdulla Ján was proclaimed heir-apparent, and in 1874 Yákúb was imprisoned by his father at Kabul. For some time previous to 1878 there had been an estrangement between Shere Ali and the British government; he had then made overtures to Russia, and had welcomed at his capital a Russian mission. In consequence of these new relations with Russia, Shere Ali was invited to receive a British mission; his refusal led, after some fruitless negotiations, to war, and hostilities began by forcing the entrance to the Khyber Pass towards the end of November. Severe fighting followed, but the English were everywhere successful. Before the end of December, Jelalabad was

occupied without resistance, and Kandahar a little later. Shere Ali fled from Kabul for Turkestan, and died at Mazar-i-Sharif towards the end of February 1879. Yákúb Khan (1849-1923) was proclaimed Amir in the following month, and on the 26th May signed a treaty of peace with the British at Gandamak. It was provided that our representative should reside at Kabul, and that the British government should defend Afghanistan from foreign aggression, the Amir receiving a subsidy; whilst the Kuram, Pishin, and Sibi valleys, the Khyber and Michni passes, were to remain under the control of the British government as part of a line of scientific defensible frontier for India. This settled matters for a time, but in September of the same year, the revolted troops of the Amir surrounded and attacked the British residency. The Resident, Sir Louis Cavagnari, and his staff, with almost the whole of their Indian guard, were cut to pieces, after a desperate and gallant resistance. Measures were immediately adopted for punishing this outrage. Sir F. Roberts, with a force of over 6000 men, after defeating the Afghans at Charásia, 12 miles from Kabul, on the 6th October, took possession of that city on the 12th, when Yákúb Khan abdicated, and put himself under British protection. All went well for two months, but early in December there were gatherings of the tribes in the neighbourhood of Kabul. Attempts to disperse them were defeated, and the British were beleaguered for ten days in their cantonments at Sherpur. The arrival of reinforcements, under General Gough, enabled them once more to take the field, and the war was continued in a desultory way.

In June 1880 Ayub Khan, a younger brother of Yákúb Khan, the ex-Amir, proclaimed a *ghaza*, or holy war, and announced his intention of marching on Kandahar, then in the possession of the British. A brigade under Brigadier-general Burrows was sent against him. On the 27th July, Burrows marched to attack Ayub at Maiwand, and was completely defeated, with the loss of over 1000 killed and wounded. A second reverse followed in August, when Brigadier-general Brooke's column was attacked, and had to retire with heavy loss, that officer being killed. Abdul Rahman Khan, who had been a pensioner of the Russian government in Samarkand from 1870 to 1880, in the meanwhile had come to terms with the British government, and had in July been recognised as Amir. The withdrawal of the army of occupation had been decided on, when news of the Maiwand disaster was brought. To avenge this, General Roberts marched with a force from Kabul on the 9th August, and reached Kandahar on the 31st. On the following day he totally defeated Ayub Khan, the Afghan camp, artillery, and baggage falling into his hands, whilst Ayub himself escaped with a handful of horse. Before withdrawing, the British troops reduced to submission some refractory tribes, and completed the evacuation of Afghanistan by the end of April 1881. Abdul Rahman Khan, with the assistance of the British government, made himself master of the whole country.

Russia's proposal, in 1882, to delimit the frontier of Afghanistan was received coldly in England. In July 1884, however, a commission was appointed to demarcate the boundary between Afghanistan and the territory of the Turkomans. General Sir Peter Lumsden was nominated by the British government, and General Zelenoi by the Russian. The line on which the commissioners were to be engaged was from Kwája Sala on the Oxus, to Sarakhs. But after the annexation of Merv and the preliminary surveys of M. Lessar, in the valleys of the Khushk and Murghab, the Russian authorities took a different view. They

contended that the Paropamisus was the true boundary of Herat, and that the district of Badghis, inhabited by Saryk Turkomans, who had proffered their allegiance to the Tsar, lay outside Afghan territory. Questions of such grave moment, it was further stated, required to be settled by the two European governments before the commissioners could enter on their duties, and General Zelenoi was, without further explanation, sent to Tiflis. General Lumsden waited for him for four months on the Murghab, with an escort of 500 men, besides followers. In the meanwhile, the Russian outposts were advanced so as to include part of the debatable land. By their occupation of Zulfikar, 50 miles south of Pul-i-Khatun, the outposts of the two nations were brought into immediate contact, and it was only through the urgent remonstrances of General Lumsden that a collision was avoided. Matters were further complicated by the attack on Panjdeh, near the fork of the Khushk and Murghab rivers, by a force under the command of General Komaroff, on the 30th March 1885, and by his seizure of this important strategical position. During 1886 the demarcation of the frontier was proceeded with, and in April 1887 the British and Russian commissioners met at St Petersburg. Protracted negotiations resulted in a compromise of the points at issue. The Amir of Bokhara waived his claims to the pasture-lands on the left bank of the Amu Daria, south of Khoja Saleh. Russia obtained the valleys south of Panjdeh for 9 or 10 miles towards Herat, and so touched the north-western frontier of Afghanistan. Britain fortified and garrisoned Quetta in Baluchistan, on the southern border of Afghanistan, and connected it with India by a railway extended to New Chaman. In 1893 the Amir agreed to a rectification of frontier, excluding Chitral, Swat, Waziristan, and Bajaur, but including Kafiristan. Abdul Rahman died in 1901. On the assassination of his son Habibullah Khan, the Amir Amanullah Khan waged a short war upon the British (1919), and the Indian government relinquished its control of Afghanistan's external affairs.

See Elphinstone's *Cabul* and Kaye's *War in Afghanistan*, and more recent works by Mallison (1878), Bellew, Raverty, Wheeler, Oliver, Daly, Gray, Holdich, Pennell (1909), and Tate (1911).

Afiun-Kara-Hissar ('Opium Black Castle'), a city of Asia Minor, 170 miles ENE. of Smyrna; pop. 20,000.

Africa, a continent of the eastern hemisphere, forming a south-western extension of Asia, to which it has been attached since Eocene times by the narrow isthmus of Suez, now pierced by a canal 90 miles long. Africa is thus constituted an insular mass of irregular triangular shape, with base on the Mediterranean, and apex at the junction of the Indian and Atlantic waters, which bathe its eastern and western shores respectively. From Cape Blanco (37° 19' 40" N.) at Bizerta, Tunis, to Cape Agulhas (34° 51' 15" S.) in the Cape Province, it stretches across 72° of latitude, or about 5000 miles, disposed nearly equally on both sides of the equator. The extreme eastern and western points are Capes Guardafui (51° 14' E.) on the Indian Ocean, and Verde (17° 32' W.) on the Atlantic, a distance of about 4500 miles. But owing to the sudden contraction of the land at the Gulf of Guinea (4° 30' N.), whence, like both Americas, India, and other peninsular masses, it tapers continuously southwards, the total area is considerably less than would seem to be indicated by these extreme distances. Including Madagascar and all adjacent insular

groups, it cannot be estimated at much more than 11,950,000 sq. m., or some 4,000,000 less than Asia or America. Of all the continents except Australia, Africa is the most uniform, heavy, and monotonous in its general outlines, unbroken by any bold projections seawards except the abortive Somali Peninsula, unrelieved by broad estuaries, bights, or inlets of any kind penetrating far inland, diversified only by the Gulfs of Cabes and Sidra (the Great and Little Syrtes) on the Mediterranean, by the Bight of Biafra at the head of the Gulf of Guinea on the Atlantic, and by the Gulf of Aden, Red Sea, and Gulf of Suez, separating it on the east side from the Asiatic mainland. Hence, although about three times larger than Europe, its coast-line scarcely exceeds 15,000 miles, as compared with the 19,000 of that more highly favoured continent.

Islands.—Geologically, Africa is nearly destitute of insular groups, almost the only islands that belong physically to the mainland being Ierba and one or two islets in the Mediterranean, and a few on the east side, such as Socotra, the 'spear-head' of the Somali Peninsula terminating at Cape Guardafui, and farther south, Pemba, Zanzibar, and Mafia, almost forming parts of the adjacent coast. Perim, Dahlak, and a few others in the Red Sea, are mere coral reefs, dominated here and there by volcanic crests. The Comoro group between Madagascar and Mozambique is also volcanic; while Madagascar itself and the outlying Mascarenhas (Mauritius, Réunion, and Rodriguez) appear to be surviving fragments of a Miocene continent, now flooded by the waters of the Indian Ocean. On the west side, the little Bissagos group alone forms a geological dependency of the mainland. Annabon, St Thomas, Prince, and Fernando Po, in the Gulf of Guinea, as well as Madeira, the Canary, and Cape Verde archipelagoes, are all of volcanic origin, the latter being separated by profound abysses of over 3000 feet from the continent. Lastly, St Helena and Ascension are mere rocks lost amid the Atlantic waters.

Relief of the Land.—Corresponding with the somewhat shapeless and uniform continental contour, is the generally monotonous character of the interior, which is relieved by no great central highlands or conspicuous water-partings at all comparable to those of the other great continental regions. Although it is not yet completely explored, the lie of the land is already sufficiently understood, at least in the main features of its general relief. We now know that the somewhat premature generalisation, which compared it to 'an inverted basin,' gives a very inadequate, if not absolutely misleading idea of its true conformation. The outer rim of mountain-ranges is not nearly so continuous and uniform as this comparison would imply; while the interior is disposed, not in one vast elevated plain, but in two well-marked physical regions—a great southern tableland with a mean altitude of over 3500 feet, falling northwards to a much lower but still elevated plain with a mean altitude of about 1300 feet. Owing to this generally high altitude, and to the almost total absence of extensive low-lying plains, such as the Russian steppes and Siberian tundras, Africa, notwithstanding the lack of vast alpine regions like the European Alps and Pyrenees, or the Asiatic Himalayas and Kuen-lun, has nevertheless a greater mean elevation (1900 to 2000 feet, Chavanne) than either Europe (950 to 1000), or perhaps even America (1900).

A line running from the Cameroons northwards to the Benue, and sweeping round Mount Alan-tika (last northern outpost of the tableland in Adamawa), eastwards to the Red Sea below Suakin, will roughly mark off the comparatively

low northern plain from the lofty southern plateau. This remarkably uniform disposition of the general continental relief is clearly established by the independent measurements of Denham and Clapperton, Barth, Vogel, Nachtigal, and Lenz for the northern, Speke, Burton, Livingstone, Stanley, and Anderson for the southern section. From these it appears that between Tipoli on the Mediterranean, and the Lake Tsad (Chad) depression in Central Sudan, or Soudan (850 feet), the mean for the Central Sahara ranges from 1300 to 1400 feet, falling in Sudan generally somewhat lower. Corresponding with these heights are those of Khartum at the confluence of both Niles in the east (1210), and Timbuktu at the great western bend of the Niger in the west (820). In the south, the plateau between the coast-range and Lake Tanganyika maintains a uniform elevation of about 4000 feet, with which may be compared Lake Dilolo, on the Upper Zambesi (4740); Linyanti, near the western bend of the same river (3500); Lake Ngami (2700); the Kalahari Desert (3900); Bushman Flat, south of the Orange River (3600). The rapid descent from the plateau to the northern plain is well marked towards the east of the continent by the Somerset (Victoria) Nile, which in the short course of 90 miles between the Victoria and Albert Nyanzas, falls from 3800 feet, the level of the upper, to 1500 feet, the level of the lower lake, no less than 2300 feet altogether.

Orography.—The southern plateau is intersected by several mountain-ranges, as yet very imperfectly explored, but apparently nowhere developing any vast orographic system. Such are the Lokinga (Mushinga) Mountains, running east and west, and forming a distinct divide between the head-waters of the Lualaba (Congo) and the streams flowing south to the Zambesi. Farther north, another important water-parting between the Congo and Nile basins is formed by the Ulegga Range, and its southern extension along the west side of the Edward and Albert Nyanzas. The mountain mass of Ruwenzori, discovered by Stanley in 1888, lies just north of the equator, between the Edward and Albert Nyanzas, and its highest peak is estimated to be 16,600 feet high. East of the Victoria Nyanza rise Kilima-Njaro (19,300) in what was till 1919 German, and Kenia (17,000) in British, East Africa. The Aberdare Range (13,000) runs south and north between Kenia and Lake Naivasha in the direction of Lake Baringo, long supposed to be one of the great equatorial lakes, but found by Thomson to be a small land-locked basin, 3217 feet above sea-level, commanded on the NW. by Mounts Chibcharagnani (12,000) and Elgon (14,000). This region, where the mountains follow the lines of the western and eastern rift valleys (see the article RIFT VALLEY), in which most of the great lakes lie, has active volcanoes in Mfumbiro, Teleki, &c. It seems to merge through the Kaffa Hills northwards in the Abyssinian uplands (10,000 to 15,000), which form the north-eastern limit of the great southern plateau. From this point the outer continental rim or coast-range stretches almost continuously through Galla Land, and along the east side of Lake Nyasa, southwards to the Nieuwveld system (8000 to 10,000) at the southern extremity of Africa. These eastern coast-ranges, spoken of by the early Portuguese explorers under the collective name of *Lupata*, may in some respects be regarded as forming, if not a backbone, at least the border-chain of one great continental highland system. The corresponding west coast-ranges are both much lower and less continuous, being interrupted by wide gaps in Damaraland, and especially on the NW. coast between the Senegal River and Morocco. They culminate in the Cameroons (13,400), at the head of the

Gulf of Guinea, and in the heights formerly known as the 'Kong' Mountains of Upper Guinea often present the appearance rather of outer scarps than of ranges actually rising above the inner tablelands.

The Atlas system (8000 to 12,000), stretching in the extreme NW. between Cape Nun, over against the Canaries, and Cape Bon, over against Sicily, runs parallel to the Sierra Nevada on the opposite coast, with which it forms a distinct physical region. Sallust's remark that this part of Africa belonged physically to Europe, has been amply confirmed by modern research, which clearly shows that even in Pliocene times, Mauritania was still connected with Iberia at the Strait of Gibraltar, and with Italy through a north-eastern continuation of the Atlas, of which Pantellaria, Malta, Gozzo, Sicily, and the Lipari group are surviving fragments, while the Balkan Peninsula merged southwards in the now flooded plains formerly frequented by elephants, hippopotami, and other large fauna. At that time the Mediterranean seems to have formed three distinct basins, with a common outlet to the Atlantic not north of the Atlas, as now, but south of that range, through the depression still marked by the Kebir and Melghir sebkhas, and the valley of the river Draa. To this extent the Sahaiian region may have been flooded by marine waters; but that it ever, since Eocene times at least, formed an oceanic bed, as is still often maintained, is an assumption that has been completely refuted by the measurements and geological researches of Oscar Lenz and other recent observers. We now know that the Sahara is a vast elevated plain, somewhat higher than the Sudan (see above), and that it consisted of well-watered and fertile lands, obliquely intersected by a great divide (the Tibesti highlands), whence flowed mighty streams, such as the Ighar-ghar north to the Mediterranean, the Messawara south to the Niger, and others east to the Nile. In some of the pools lying along the sandy beds of these rivers, the crocodile still survives, while the elephant, as well as the camel, formed part of the Mauritanian fauna within the historic period. In fact, the Sahara was what the Sudan still is—a thickly peopled land, abounding in natural products, diversified with broad belts of tropical forests, arable tracts, and grassy steppes, according to the nature of the soil, and greater or less abundance of moisture. This is also the general character of the great southern tableland, which, like the northern plain, has also in the Kalahaii its desert zone, both zones corresponding to similar arid regions, such as the Gobi, the Turkestan, Persian, and Arabian sands, the salt plains of Utah, the Australian and Bolivian wastes, all somewhat symmetrically disposed on either side of the equator, and due to cosmic or atmospheric causes, which have not yet been clearly elucidated.

In its geological constitution, Africa presents the appearance of great stability and antiquity. Unlike those of other continents, the seaboard is subject to scarcely any movements of upheaval or subsidence, except on the NE. coast between the Nile delta and the Gulf of Sidra (an area of subsidence), and parts of the Moroccan and Red Sea coasts (areas of upheaval). Earthquakes are confined mainly to the Atlas, which belongs physically rather to Europe than to Africa, and igneous disturbances are restricted on the west side to the Bight of Biafra (the Cameroons, Fernando Po, and other adjacent islets). But on the east side, the volcanic system is much more highly developed, stretching from the Comoro Islands through Masai Land (Kilima-Njaro, Kenia, Elgon, &c.), northwards to the Danakil country, and the volcanic islets in the Red Sea. The lava-fields of

the Masai plateau appear to be the most extensive on the continent, and at many points present signs of recent activity. But elsewhere the old plutonic prevail immensely over the more recent eruptive rocks, just as the older sedimentary do over the later tertiary and quaternary formations. Both orders appear to be generally intermingled, and largely associated with semi-crystalline and metamorphic forms, such as the schists, gneisses, gray-wackes, and hornblendes, about Kilima-Njaro and many other places. The Kamasia Range (8000 to 9000), N.E. of Victoria Nyanza, is essentially metamorphic (white striated felspar, quartz, and black mica), while shales and flaggy sandstones form the geological basis of the East African carboniferous series, which extends in a narrow strip from near the equator continuously to the Cape. Hard granite forms the bed of the Orange River, and asbestos, soapstone, coal, iron, and copper were amongst the specimens collected by Farini in the Kalahari steppe. Metamorphic rocks, again, prevail in the Congo basin, where iron and copper ores also abound, and where plutonic systems succeed above Stanley Pool (Johnston). Syenite, and other granites, with old sandstones, are the characteristic features of Upper Egypt and the Nubian steppe; while Abyssinia has also a granitic base underlying dolerites, trachytes, and crystalline slates. But here the eastern slopes, skirted or traversed by the great volcanic zone, are strewn with obsidian, pumice, and other recent lavas.

A great diluvial plain stretches from this region through Senaar southwards to the crystalline slates, associated with magnetic iron ores of the Baginze slopes, about the source of the Welle. Even the Sahara, long supposed to be a recent marine basin, is characterised by the absence of late sedimentary rocks and marine fossils, and by the prevalence of old sandstones, quartz, and carboniferous limestones, largely disintegrated by weathering. It also abounds in rich saline deposits, forming a chief article of trade with the neighbouring Sudan, which is distinguished by the almost total absence of salt, the prevailing formations here being crystalline rocks, granites, diorites, slates, gneiss, again associated with sandstones in the higher ranges. In the Guinea uplands the sandstones overlie the granites, which in the Teggele group (Kordofan) pass over to porphyries and syenites, with gneiss interspersed with extensive diorite and auriferous quartz veins. Gold, mined by the ancient Egyptians at Mount Elba, Red Sea coast, occurs also in many other places, as in Upper Guinea, the Lower Zambesi, and Transvaal; and gold dust has at all times formed a chief article of export. But iron and copper are the characteristic metals, ferruginous ores abounding almost everywhere, and copper in Namaqualand, the Congo basin, Dar-Fertit, and many other places. The basin of the Vaal is one of the richest diamantiferous regions on the globe. In this southern region, granites and crystalline slates form the substratum of an extensive series of fossiliferous rocks, descending from the outer rim (Nieuweveld) down to the coast in a series of terraces ('karroos'), which are baked clay in the dry season, but flowery and grassy meads in the wet season.

The African hydrographic are drawn in bolder lines than its orographic systems. Here also a certain symmetry prevails, the two great southern basins of the Congo and Zambesi balancing those of the Nile and Niger of the northern plain, while the secondary Orange and Limpopo in the extreme south find their counterparts in the Senegal and Draa of the NW. The Zambesi and Limpopo, together with the Rovuma, Juba, and a few other coast streams, flow to the Indian Ocean; all the others, together with the Cunene, Koanza,

Ogowe, Volta, Gambia, Tensift, Muluya, and Mejerdah, to the Atlantic, either directly or through the Mediterranean. Nearly all are still entangled in the intricacies of the interior, hence are obstructed either along their middle or lower courses by formidable falls and rapids, such as the stupendous Victoria Falls on the Zambesi; the Yellala and Isangila on the Lower, and Stanley on the Middle Congo; the so-called 'Six Cataracts,' the Ripon, Murehison, and many others, all along the Nile above Egypt; the 'Hundred Falls' of the Middle Orange. Freest from these impediments are both the Niger and its great eastern affluent the Benue, which latter affords a clear navigable highway into the very heart of Sudan. Here a scarcely perceptible divide, with a continuous waterway in very wet seasons, separates the Benue from the Shari, which gives farther access by water northwards to Lake Tsad, south-eastwards towards the Nile and Congo basins. In this recently explored region, the Shari, with its numerous head-streams, approaches the Makua-Welle, which its discoverer, Schweinfurth, supposed to flow from the Monbuttu uplands NW. to the Tsad, but which the later explorations of Grenfell, Lupton, and Junker send SW. through the Ubangi to the Congo basin. For other points once doubtful, such as the course of the Ogowe, Alima, Sankuru, the drainage of Lake Leopold, &c., mostly cleared up in recent years, see below under History of African Exploration.

But apart from its great rivers, including the historical Nile, earliest seat of human culture, Africa possesses a magnificent equatorial lake system, elsewhere unrivalled except by the great North American lacustrine basins. These are the crowning glory of modern African research, all having been revealed to science by English-speaking explorers (Livingstone, Speke, Grant, Burton, Baker, Stanley) since the middle of the 19th century. They are grouped towards the east side of the continent between 15° S. and 4° N. lat., and all stand on the southern tableland, draining seaward through the Zambesi (Nyasa, with outflow Shiré), the Congo (Tanganyika, with intermittent outflow Lukuga), and the Nile (Alexandra Nyanza, Victoria Nyanza, Edward Nyanza, and Albert Nyanza, with outflow Somerset Nile). The Alexandra (Akanyaru) drains north-eastwards through the Alexandra Nile (Kagera) to the Victoria, queen of African lakes, and, next to Superior (31,200 sq. m.), the largest fresh-water basin (26,000 sq. m.) on the globe. The Shimiyu, another affluent from the south, may be regarded as the farthest head-stream of the Nile, which thus rises about 5° S. lat., flowing thence northwards to the Mediterranean for some 3700 miles—a course accordingly next in length to that of the Missouri-Mississippi, the longest river in the world. Albert Nyanza and Mwutan Nzigé were long taken as alternative names of a continuous sheet of water since ascertained to form two distinct lakes. The northern, now known as Albert Nyanza, is a kind of backwater of the Nile; and the southern, named by Stanley (who visited it in 1876 and 1889) (Albert) Edward Nyanza, flows into the northern one by the Semliki River. In 1887 Emin Pasha reported his conviction that the Albert Nyanza (q.v.) is silting up. The outflow of Tanganyika was also a somewhat doubtful point, until the surveys of Thomson, Hore, and Wissman made it quite certain that it drains westwards through the Lukuga, at least intermittently to the Congo. This adds considerably to the drainage area of the Congo, which ranks next to the Amazon for volume, discharging probably as much water as all the other African rivers together (Reclus). Since its identification by Stanley with the Lualaba, its farthest head-stream

appears to be the Chambeze, an eastern feeder of Lake Bangweolo, rising in 10° S. lat., 33° E. long., and giving to the Congo system a total length of considerably over 3000 miles.

The equatorial lake system is thus distributed among the three great fluvial basins of the Zambesi, Nile, and Congo. But scattered over the continent are several other lacustrine basins, varying greatly in size, which have no seaward outflow, but form independent, or, at all events, now isolated centres of inland drainage. By far the most extensive of these are Lakes Tsad (Chad) and Ngami, again symmetrically disposed on either side of the equator, and fed, the former by the Shari and Komadugu, the latter by the Tonka. Both vary greatly in extent with the wet and dry seasons, and there is good reason to believe that formerly both had emissaries, Tsad to the Benue-Niger (as still in exceptional seasons), Ngami to the Limpopo basin. Ngami is now dwindling. Alpine lakes are represented by the Abyssinian Lake Tana (Tsana or Dembea, 6100 feet), which has an area of some 1200 sq. m., and a depth of over 300 feet. It is fed by numerous alpine streams, amongst which is the Abai, farthest source of the Bahr-el-Azraq, or Blue Nile, which, after sweeping round the Abyssinian plateau, joins the Bahr-el-Abiad, or White Nile, at Khartum. Before the discovery of the great lakes, Tsana was considered by many geographers as the chief reservoir and farthest source of the main stream. The great oceanic and inland hydrographic systems of the continent may now be tabulated thus:

SEAWARD BASINS—	Area in sq. m.
Nile	1,500,000
Congo	1,350,000
Niger	1,150,000
Zambesi	850,000
Orange	400,000
Limpopo	200,000
Senegal	160,000
Ogowe	150,000
Smaller basins and dried-up areas of seaward drainage	3,000,000
Total seaward	8,700,000
INLAND BASINS—	
Tsad	750,000
Ngami	320,000
Igharghar, Messawara, and other dried-up areas of inland drainage	1,850,000
Total inland	2,920,000

Climate.—Above all the great divisions of the globe, Africa is distinguished by the general uniformity of its climatic phenomena, a circumstance due to its massive form and intertropical position. In the region approaching nearest to the northern or southern equinoctial lines, rain falls throughout the year, thanks to the opposing trade-winds, which, by neutralising each other, often preserve the stillness of the atmosphere, and enable the local vapours to condense and precipitate themselves on the spot. In the northern hemisphere, a zone of two wet seasons stretches from the equator to the 15° lat. In summer, copious showers are caused by the moisture-bearing SW. winds; in winter, the NW. currents become in their turn the bearers of heavy rain-charged clouds to the southern plateau. But on both sides of the torrid zone, comprising about seven-tenths of the whole continent, the difference in the disposition of the winds causes a corresponding contrast in the rainfall. Here the trade-winds maintain their normal direction constantly, or with but slight temporary deviations. Blowing from the NE. in the northern, from the SE. in the southern hemisphere, they divert to the equator most of the vapours crossing their path, leaving elsewhere clear skies and arid lands. Thus it happens that

Africa has two almost completely barren zones of rocks, gravels, marls, clay, and sand—the Sahara and Libyan desert in the north, Kalahari and other wastes in the south. This regular disposition of the climates is completed by the regular alternation of winds and rains in the zones of Mauritania and the Cape, both belonging to the region of sub-tropical rains, which fall in the respective winters of each hemisphere. Africa is thus disposed from north to south in successive gray and more or less intensely green belts, whose limits coincide in several places with the isothermals, or lines of equal temperature. The lines indicating mean annual temperatures of 68° and 75° F., traverse, in the north, the Mediterranean seaboard and the Sahara respectively; in the south, the Orange basin and a zone stretching obliquely from Mozambique to the Cameroons; while the area of greatest mean heat (82° F.) is comprised within an irregular curve inclosing the Upper Nile basin between Khartum and the Albert Nyanza north and south, Lake Tsad and Massowah (Massawah) west and east. But, through defective or incomplete observations, the general temperature has often been exaggerated; that of Gambia, for instance, has been reduced by the Colonial Official Report for 1886 to about 70° F. for January, and 80° to 82° for July at noon. Nevertheless, owing to the far greater accompanying moisture, these relatively moderate heats are far more oppressive than those of the Beluchistan coast and other drier regions, where the glass constantly rises to 115°, and even 120° F. and 125° F. For the same reason the climate, except on the Mediterranean, Saharian, Red Sea, and extreme south coasts, is nearly everywhere malarious round the periphery of the continent—that is, on the low-lying and generally marshy coast-lands between the outer rim and the sea. It is the same in the Chambeze, Malagarazi (Unyamwesi), Shari, and other inland districts, which are either constantly or periodically under water. But elsewhere, with due precautions, the continent cannot be regarded as insalubrious; and the Sahara, for instance, is distinctly a healthy region, although, owing to rapid radiation, the hot days are here succeeded by cool and occasionally even frosty nights. The mean annual rainfall ranges from under four inches in the Sahara and about ten in the Kalahari, to sixty and eighty about the equator, and from eighty upwards on the Guinea coast. Under all these conditions, Schweinfurth, for many years a resident in Africa, considers that a European colonisation of most of this continent is a possible future contingency.

Flora.—About 41 per cent. of the surface is said to be either desert, or under scrub, or otherwise absolutely waste, and 35 per cent. steppe, or nearly treeless grass-grown savannah, leaving only 24 per cent. for forest and arable lands. But too much weight cannot yet be attached to such broad statements as these, and all that can be concluded from a comparison of recent observations is, that the grassy tracts appear to be far more and the woodlands far less extensive than had been supposed. The continuous forest growths are now known to be confined mainly to the vast equatorial region between the Upper Zambesi and Sudan, and to some isolated tracts about the Abyssinian plateau, in the Moroccan Atlas, all along the Guinea coast, about the Middle Limpopo and Zambesi, and in parts of Masai Land and the Upper Nile basin. From Sierra Leone to the river Ogoway, along the coast, the one prevailing landscape is that of endless forest. This is, in fact, part of the forest region—the forest belt, which has a distinctive fauna and flora, and which extends eastwards, near the equator, more than half-way across

Africa to Lake Victoria Nyanza and the western shores of 'Tanganyika' (H. H. Johnston, *The River Congo*, p. 13).

In the extreme north, African and South European species intermingling with some local varieties, and here are found the olive, date, and cork, with seven other kinds of oak, besides the eucalyptus, lately introduced from Australia, all flourishing side by side. Nevertheless, the graminaceæ are predominant, and vast tracts in Algeria and Tunis are covered with halfa (alfa), largely exported to England for paper-making. The papyrus itself, whence the word paper, still lingers in the Upper Nile, although in the Lower Nile the lotus and other characteristic plants have been mostly replaced by cereals, cotton, tobacco, and other economic species. Beyond Egypt, the date gives place to the düm and deleb palms, wheat and rice to durrha; while in the forest regions of Sudan and Guinea, the prevailing species are the magnificent baobab (*Adansonia*), the banana, butter-tree, ebony, *Elaeis guineensis* or oil-palm, which yields the palm-oil of commerce, the musanga, the mangrove, ground-nut, dragon-tree, acacias, mimosas, and other gum-trees, succeeded, in Galla and Somali Land, by aromatic shrubs and the coffee shrub, supposed to take its name from the Kaffa country, south of Abyssinia. Another variety of this shrub is indigenous in Liberia, whence it has lately been introduced into Ceylon and other coffee-growing lands. Indigenous to Africa is also the cotton-plant, which, like indigo, is widely cultivated in Egypt and Sudan, and which grows wild in many places as far north as 19° N. lat. But of all African floras, the most characteristic, as well as the richest and most diversified, is that of the Cape region south from the Orange River. It consists chiefly of grasses, shrubs, bushes, and lovely ferns, and heathers in greater variety than is found even in the richest European lands. Here, one might fancy, had been gathered, as in a last refuge, the diverse growths of the vanished 'Lemurian' continent, which is by some geologists supposed to have occupied the Indian Ocean down to the close of Miocene times. This supposition is strengthened by the character of the Madagascar flora, which possesses over forty genera peculiar to itself.

Fauna.—Africa is the peculiar home of the large fauna, many of which, owing to the absence of great central mountain barriers, freely roam from one end of the continent to the other, without undergoing any special modification of type. Such, among the carnivora, are the lion, far finer than its Asiatic congener, and met everywhere, from the Atlas and Nubia to the Cape; the panther and leopard, but not the tiger; the hyena, fox, and jackal. The great herbivora are represented by the elephant, differing both from the Asiatic and from the smaller and now extinct Mauritanian variety; the rhinoceros, of which there appear to be at least three species, including the one-horned, now known to occur in Nubia, and perhaps also in Wadai; the buffalo, also in several varieties; the giraffe, elsewhere extinct, but here still ranging from north to south, a remark applicable also to the ostrich, as well as to the unwieldy hippopotamus, which, like the crocodile, frequents all the large rivers and lakes. Africa is also the special home of the gnu, and of several other species of antelopes, sometimes still met in countless herds on both sides of the equator. The monkey family is also spread over the whole continent, where it is represented by numerous types, including the small Barbary variety, the dog-faced baboon, the Galago lemur, the beautiful colobus of the eastern regions, besides the anthropoid chimpanzees and gorilla of the west equatorial districts. Peculiar also are

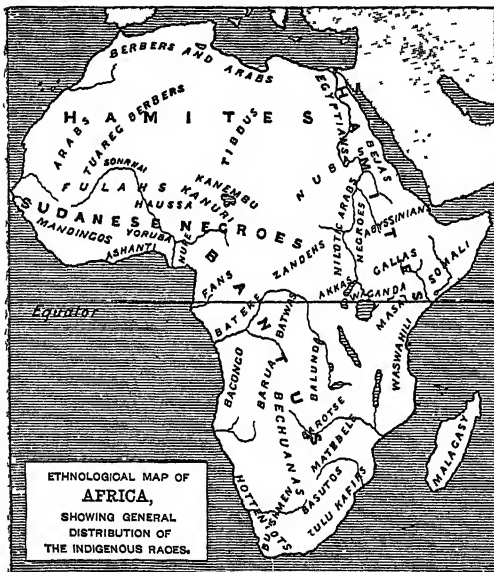

such equidæ as the zebras and the pigmy Mauritanian ass; although the horse itself, like the camel, appears to have been reintroduced by the Arabs. Of land mammals there are altogether enumerated about 480 species peculiar to this continent, amongst which are 95 of the simian and 50 of the antelope family.

Equally distinct is the avi-fauna, which, besides the ostrich, includes the secretary, ibis, guinea-fowl, weaver-bird, roller-bird, love-bird, waxbill, whydah, sun-bird, parrots, quail, and several other indigenous species. Reptiles and insects also abound, comprising the huge python, many poisonous snakes, termites, locusts, and two little winged pests highly destructive to domestic animals—the tsetse fly, which ranges from Mozambique to Senaar, fatal to the horse, camel, ox, and dog; and the donderobo, south of Kilima-Njaro, which attacks the ass, goat, and sheep. The tsetse especially is one of the great impediments to the progress of culture, although it is said to disappear as systematic cultivation of the soil is developed.

Inhabitants.—Recent authorities roughly estimate the population of Africa at 140,000,000 to 210,000,000, giving a density very much less than that of Europe, but still considerable, regard being had to the great extent of absolutely desert, forest, and other waste lands. According to the nature of soil and climate, the population is distributed very unevenly over the surface, being massed somewhat densely in the Nile delta, in the Upper Nile Valley, and generally throughout Sudan, less thickly over the southern plateau, and very thinly in Mauritania and Tripolitania; while large tracts, especially in the Western Sahara, the Libyan and Kalahari wastes, are absolutely uninhabited. Of the whole number, probably less than 3,000,000 are recent immigrants from Europe, settled chiefly in the extreme north (Egypt and Algeria) and in the extreme south (the Cape Province, Natal, and the Transvaal). About 34,000,000, all of *Semitic* stock, are intruders from Asia, some in remote or prehistoric times (3,000,000 Hinyarites in Abyssinia and Harar from South Arabia), some since the spread of Islam (over 30,000,000 nomad and other Arabs, chiefly along the Mediterranean seaboard, in West Sahara, and Central and East Sudan). All the rest, numbering 100,000,000 to 175,000,000, may be regarded as the true aboriginal element. These are classed by Lepsius in two great physical and linguistic groups: *Hamites* in the north, *Negroes* in the south, meeting and intermingling in the intermediate region of Sudan. But this broad grouping is inadequate to explain the present conditions, for there are probably more than two indigenous stock races, and certainly more than two stock languages in Africa, while the races themselves are intermingled in the southern plateau quite as much as, if not even to a greater extent than in Sudan. The Arabic term, Beled-es-Sudan, 'Land of the Blacks,' answers to our somewhat obsolete expressions *Nigritia*, *Negroland*, which is commonly regarded as the true home of the black race. Certainly more ideal Negro peoples—that is, ideal in their departure from the European standard—are found in Upper Guinea, for instance, and among the Bari and Shilluk Nilotic tribes, than amongst the Bantus, as the Negro or Negroid peoples of the southern plateau are now collectively called. In general, it may be said that, viewed as a whole, the Negro family presents as profound deviations within itself as do the Caucasian and the Mongolic—that is, the two other great families of the eastern hemisphere. The deviations are even greater, if in the typical Negro group are to be included not only the aberrant Hottentots of the extreme SW., but also the pigmy peoples, such as

the Bushmen of the Kalahari steppe, the Obongos of the Gabun, the Akkas south of Monbutland, and the diminutive Batwas, averaging only 4 feet 3 inches in height, discovered in 1886 by Dr Ludwig Wolf in the Sankuru (Middle Congo) basin. These western Negritos, scattered over the southern tableland, seem to stand in the same relation to their taller neighbours as the eastern Negritos (Andamanese, Malayan Samangs, Philippine Aetas, the now extinct Kalangs of Java) to their taller Papuan neighbours; whilst their languages, such as that of the Bushmen, abounding in, to us, unpronounceable sounds known as 'clicks,' are said by some to form a sort of connecting link between articulate and inarticulate speech.

Radically distinct from these idioms is the Hot-tentot, which itself differs fundamentally from the Bantu, a vast linguistic family, current amongst nearly all the other peoples of the plateau, from the Ama-Khosas of Kafirland northwards to the Wa-Gandas of the Somerset Nile and the Duallas

of the Cameroons. This wonderful Bantu group, comparable in extent as well as in complexity of structure to the Aryan, Finno-Tatar, Athabaskan, and other widespread families in the other continents, gives a certain unity to the Bantu populations, who could not otherwise be distinguished by any hard and fast line from their northern Negro and Negroid neighbours in Sudan. Here the diversity of speech is as great as is the diversity of types produced by immemorial interminglings with the conterminous Hamite peoples. But amid the general chaos of tongues awaiting future classification, certain relatively large linguistic groups have already been determined, and these have so far helped to diminish the prevailing confusion. Such are the *Mandangan*, with many branches, in Senegambia; the *Sonrhai* of Timbuktu and the middle Niger; the *Fulah* and the *Hausa*, both widely diffused throughout Western Sudan; the *Tibbu* (*Tedaga* and *Dasaga*), ramifying from South Fezzan across the Central Sahara to Kanem, Bornu (Kanui), Wanyanga and Dar-Fur (Baele and Zoghawa); lastly, the *Nuba* of Kordofan and the Middle Nile above the Egyptian frontier. The Nubas, once supposed to be related to the Fulahs, are now known to be true Negroes, whose type is preserved in Kordofan, and greatly modified in the

Nile Valley (Keane). For some further details as to the relationships of the various Hamitic, Negro, Negroid, and mixed stocks inhabiting these regions, the article ETHNOLOGY in this work should also be consulted. The researches of Nachtigal also helped to determine the hitherto doubtful position of the Tibbus (the Garamantes of the ancients), who occupy the whole of Eastern Sahara, from about 12° E. long., and whose true home appears to be the Tibesti highlands. Physically they are not to be distinguished from their Tuareg (Hamite) neighbours; but the race has been gradually displaced southwards to the Tsad basin, where their speech, fundamentally distinct from the Hamitic, has been adopted with considerable modifications by the Kanuri, Kanembu, and other true Negro peoples. Other large Negro groups are the Batta of Adamawa; the Nupe and Yoruba of the Lower Niger; the Mosgu (Masa), south of Lake Tsad; the Maba of Wadai, the Dinka, Shilluk, Bari, and Monbutta of the Upper Nile and Upper Welle; lastly, the Zandeh (Nyam-Nyam) and Fan, occupying most of the comparatively lately explored region between Sudan and the Congo and Ogowe basins. All of these appear to be true Negroes, except the Fans, who have in recent times reached the west coast about the equator, and who are described as quite distinct (Hamites?) from the surrounding black populations (Burton, Lenz).

The remainder of North Africa, except where encroached upon by the intruding Semites (see above), is the proper domain of the Hamites—that is, the African branch of the Caucasian family. Their physical type is essentially Mediterranean, often characterised by extremely regular features, and in places even by blue eyes and fair complexion (Aures uplands, Algeria). But their language bears no distinct relation to any other Caucasian form of speech, beyond a certain faint resemblance to the Semitic sufficient to suggest a possible primeval Semitico-Hamitic organic tongue. It has a geographical range in the north analogous to that of the Bantu in the south, being spoken with great dialectic diversity by the Berbers (Imoshagh) in Western Sahara (Tuaregs), and Mauritania (Shluhs, Kabyles, Mzabs), and in the east by the Gallas, Somalis, Masai (?), Afars (Danakil), Agau, and Bejas—that is, generally between the Nile basin and the Red Sea. But it is now extinct in Egypt, where Arabic is current, and where the old Hamitic speech is represented only by the liturgical language of the few surviving Christian Coptic communities.

In its inhabitants, as well as its natural history, Madagascar forms a region apart, the dominant Hovas of the central plateau, the Sakalavas of the west, and the Betsimisarakas of the east coast, being either of pure or mixed Malay stock. The Malagasy language also, which is spoken with a certain uniformity all over the island, is an outlying branch of the great oceanic (Malayo-Polynesian) family, which stretches thence eastwards to Easter Island. Nevertheless, there is evidently a considerable intermixture of black blood, due to the importation of slaves from the Mozambique coast, and possibly also to the presence of a Negro element in the island before the arrival of the Malayan intruders in Madagascar.

The foregoing remarks will be rendered more intelligible by the subjoined general scheme of all the African races:

I.—NEGRO AND NEGROID PEOPLES.

NEGROS (Pigmes)—

Bushmen (San).....	Kalahari Desert.
Batwas.....	Sankuru River, Congo Basin.
Obongos.....	Ogowe Basin.
Akkas.....	South Monbutland.

NEGRO AND NEGROID PEOPLES—*continued*.

HOTTENTOTS (Khoi-Khoi).—

Namaqua.....Great and Little Namaqualand.
Korqua.....Upper Orange, Vaal, and Modder rivers.
Griqua (half-castes).....Griqualand West.

BANTUS—

Zulu-Kafirs, Basutos, Bechuanas...South from the Limpopo.
Makua, Maibele.....Between Limpopo and Zambezi.
Manganya, Wanyika.....Lake Nyasa.
Barotse, Barua, Balunda.....Between Zambezi and Congo.
Wasuakili, Wanaka, Wapokomo.....East Coast.
Waganda, Wanyamweru, Walega.....Equatorial Lakes.
Ovaherero, Ovembo, Bacongo, Bateke, Duallo.....West Coast.

SUDANESE NEGROIDS—

Kru, Fantr, Ashanti, Yoruba, Nupe.....Upper Guinea.
Mandingo, Wolof, Bambara, Sonrha.....Senegambia.
Hausa, Batta, Kanuri, Bagirmi, Mosgu.....Central Sudan.
Kanem.....Central Sudan.
Maba, Nuba, Dinka, Shilluk, Bari, Monbuttu.....Eastern Sudan.
Zande.....Eastern Sudan.

II.—HAMITIC PEOPLES.

MIXED AND DOUBTFUL HAMITES—

Fans.....Ogowe Basin, thence inland.
Fulahs.....West and Central Sudan.
Tubbs.....East Sahara.
Agas.....Abyssinia.
Masa.....Masailand.
Fellahin.....Egypt.

TRUE HAMITES—

Shilluk.....Morocco.
Berbers { *Mzab, Kabyle*.....Algeria, Tunis.
 Tuareg.....West Sahara.
Gallas, Somali, Afar (Dandini), Beja.....North-east Coast.

III.—SEMITIC PEOPLES.

Arabs...Mauritania, West Sahara, Central and West Sudan.
Hymerites (Amhara, Tigre, Shoa).....Abyssinia.

Religion and Social Condition.—Speaking generally, the northern Hamites and Semites are Mohammedans and stock-breeders, the southern Bantus nature-worshippers and agriculturists; all these factors intermingling in the intervening zone of Sudan. The chief exceptions to this broad statement are the Christian Abyssinians (Monophysite sect); the Hottentots, who are mainly cattle-breeders; and the Algerian Berbers, who prefer tillage to pasturage. A nomad existence prevails in East Sudan; a settled, in Central and West Sudan. Throughout the whole of this region Islam continues to encroach on heathendom; it is now firmly seated on the Upper Niger and Upper Senegal; it has already penetrated to various points of the Senegambian and Guinea coasts; it has spread with the conquering Fulahs to the southern limits of Adamawa, and has crept down the east coast from Somaliland to Zanzibar and Mozambique. Thus fully one half of the continent has accepted its tenets, which have on the whole had a beneficent influence on the Negro peoples, by developing a taste for clothing and other social comforts, by suppressing cannibalism, and shaking their faith in the medicine man. Elsewhere, progress is barred by the all-prevailing fetichism, intimately associated as that system is with the baneful practice of witchcraft. Cannibalism also in its most repulsive forms holds its ground among the Monbuttu, Zande, and Fans, a central zone of anthropophagy apparently traversing the continent from the west coast along the equator nearly to the great lakes, and stretching northwards to the Upper Shari basin. On the other hand, slavery, while maintained by Mohammedanism as a necessary social institution, has, by the intervention of the European powers, almost ceased to be an object of foreign traffic. The horrors of the 'middle passage' no longer vex the conscience of Christendom, and the Arab slaver has nearly disappeared from the Red Sea and Indian waters. Christianity is progressing amongst Basutos and other Southern Bantus, and throughout Uganda.

The *political* map of Africa in the end of the 19th century and beginning of the 20th underwent prodigious modifications, the progress of exploration and mutual jealousy having stirred European

nations to further appropriations in this continent; so that now, save Liberia, Abyssinia, and Egypt, the whole of Africa is under the direct or indirect control of European states—Great Britain, France, Portugal, Spain, Belgium, and Italy.

The British Empire includes in Africa some 2,500,000 sq. m.—a fifth of the British Empire scattered over the globe, and about twenty times the area of the motherland, Great Britain and Ireland. If to this we add 1,400,000 sq. m. for the virtual protectorate of Egyptian Sudan and mandatory territories, we get a grand total of 3,900,000 sq. m. In this are reckoned the crown colonies of Gambia and Sierra Leone (with a protectorate), on the Senegambian coast; Gold Coast Colony, with a coast-line of 350 miles along the Gulf of Guinea, and a protectorate including the Ashanti *hinterland*; and Lagos, on the Bight of Benin, now united with Nigeria. Nigeria is an enormous territory, including the whole of the lower basin of the Niger, and extending to Lake Tsad (Chad) on the north-east. In Nigeria is included Sokoto, late capital of the Fulah Empire. Walvisch Bay, on the coast of South-west Africa, is also British, and is a part of the Cape Province. The Union of South Africa, as constituted by the South Africa Act of the Imperial Parliament in 1909, includes the Cape of Good Hope, Natal, Orange Free State, and Transvaal Provinces, with which are associated Swaziland, Basutoland, Bechuanaland, and Rhodesia, though these are not within the Union. Nyasaland, formerly the British Central African Protectorate, Zanzibar, Uganda, and British Somaliland are protectorates, Kenya a colony and protectorate, in Central and East Africa. Already in British occupation, Egypt, which was officially still part of the Turkish Empire, became in 1914 a British protectorate. Its independence was acknowledged in 1922. After the Mahdi's rebellion, Dar-Fur, Kordofan, Senaar, Khartum, other parts of Nubia, and the Equatorial Province reverted to a barbarous independence; but since the Sudan campaign in 1898 these provinces have been administered jointly by Egypt and Britain as the Egyptian Sudan, under a convention signed in 1899. Mauritius, Socotra, and other islands are also British.

France occupies or has influence over about a third of the whole area of Africa; her African domain may be estimated to cover 4,000,000 to 4,500,000 sq. m., extending from the Mediterranean to the Congo River, and from the west coast to the watershed between the basin of the Congo and that of the Nile. It includes Algeria, with a protectorate over Tunis and most of Morocco; Maurétanie, Senegal, French Guinea, the Ivory Coast, between Liberia and Gold Coast Colony; Dahomey, between Togoland and Nigeria; with the enormous *hinterlands* of French Sudan and Sahara, which are, by the Anglo-French agreement of 1899, strictly delimited from the Egyptian Sudan and Sahara. Wadai, a powerful sultanate between Dar-Fur and Lake Tsad, on which the neighbouring kingdom of Bagirmi was dependent, was occupied by France in 1906. Gando is partly French, and some smaller states on the Niger. But Tibesti and several other districts in the Eastern Sahara are still practically independent. French Equatorial Africa (French Congo) extends from the coast along the north bank of the Congo and Ubangi rivers, and cut into by cessions to Germany in 1911, which reverted in 1919, joins French Sudan in the north. On the east coast is the French Somaliland Protectorate (Côte des Somalis), including the old colony of Obok; and the vast island of Madagascar is French, with the Réunion and Comoro Islands.

Portugal holds, on the west coast, her old possessions of Angola and Benguela, with a small tract just north of the Congo mouth (collectively form-

ing Portuguese West Africa), a small part of Guinea, Madeira (reckoned a part of Portugal), and St Thomas and Prince's Islands, and Cape Verde Islands; and on the east, Mozambique, with dependencies between Cape Delgado and Delagoa Bay, and along the Zambesi, past Tete, to Zumbo (Portuguese East Africa). Spain has possessions or protectorates (some of them reckoned as parts of Spain) in Morocco, Río de Oro, and the Canaries; the district of the Muni and Naya rivers, north of the Gabun; and Fernando Po and Annobon in the Gulf of Guinea. Germany had till 1919 the coast-lands between the Kunene and the Orange River (except the British territory of Walvisch Bay), extending inland to 20° E. long., farther north to 21°, and farther north still, at about 18° S. lat., to the Zambesi near the Victoria Falls; Cameroon, from the Gulf of Guinea to Lake Tsad, to which is attached Adamawa, with a slice ceded from French Equatorial Africa in 1911; Togoland, between the British Gold Coast Colony and Dahomey; and on the east side, German East Africa, from the Rovuma River to Victoria Nyanza, and from the coast to Lake Tanganyika. These colonies are now governed by mandates of the League of Nations. Italy has since 1884 occupied Eritrea (the Red Sea coast from Ras Kasar southwards to beyond As-ab); her protectorate over Abyssinia came to a disastrous end at Adowa in 1896; but in the war of 1911-12 she wrested Libya (Tripoli and Benghazi) from Turkey. Italian Somaliland extends from Bandar Ziyada to beyond the Juba. The Congo Free State, founded in 1885, became the Belgian Congo when it was taken over by Belgium in 1907-8, and has an area of 910,000 sq. m., with a population estimated at about 20,000,000.

In 1904-13 Morocco was the subject of many European negotiations; and armed intervention was more than once resorted to. In addition to her claim to Ifni and the adjoining coast, Spain had long held a number of stations on and off the north coast. In 1912-13 the zone north of a line running from the Muluya River to Kas-el-Kebir and the Atlantic was assigned to Spain, except Tangier and its district (140 sq. m.), which were placed under an international council. The Ifni claim was recognised. The remainder of Morocco became a French protectorate (1912). Under pressure from Germany at Agadir, France agreed, in compensation for advantages in Morocco, to readjust the boundaries of Cameroon and French Equatorial Africa. This gave Germany a net gain of 100,000 sq. m., with access to the Congo and the Ubangi.

Abyssinia, released from the short-lived Italian protectorate, is not merely in all other respects a native state, but cherishes relations with France and Russia as well as with Britain, and has pushed her frontiers southward. Liberia (q.v.), which, as inhabited by Africans or persons of African descent, is also a native state, is a republic on the model of the United States. Till 1900 the two Boer states, the Orange Free State and the Transvaal, now original provinces of the Union of South Africa, were in a sense African states, though their civilisation was European in origin. Even within the European spheres of influence many of the tribes are practically as free—and as savage—as ever they were. The interior of Somaliland is utterly savage, though the coasts are British, French, and Italian; as are also the regions round Uganda. The Hausa states of the Western Sudan are now either occupied or administered by European Powers.

Abyssinia is Christian; the Zulu and Bantu states, with Dahomey, are pagan; the rest mainly Mohammedan. The region held by the nomad predatory tribes is mainly the Sahara—Tuareg Hamites and Arabs in the west, Tibbu Hamites in the east. Of the lands under tribal organisation,

the most extensive are those of the Monbuttu and of the Zandeis (Nyam-Nyams), about the Nile-Congo water-parting.

Exploration.—The term 'Africa,' originally the name of a small tract on the north coast still surviving in the *Friga* of the Tunisian Tell, was extended under Roman influences to the whole of the 'dark continent,' just as the 'Asia' of the Cayster Valley in Ionia had under Greek influences been extended to the whole of the eastern world. It was the Ethiopia of Homeric, and the Libya of later Hellenic times, terms vaguely applied to the region stretching away to the setting sun, and with undefined southern limits. But neither Greeks nor Romans ever extended their knowledge much beyond the northern verge of the Sahara, and although the Nile Valley was the earliest seat of human culture, with stupendous monuments dating back 4000 years before the Christian era, Africa was till lately the least-known division of the globe. Its exploration may be said to have begun with the expedition sent by Sankhara of the 11th (Theban) dynasty to the land of Punt (Somaliland), as recorded on the Wady Hammamat inscription (2400 B.C.), and after a lapse of over 4300 years, this work of exploration is still far from complete. After the circumnavigation attributed by Herodotus to Necho, son of Psametik I. (26th or Sate dynasty, 620 B.C.), and the naval expedition of the Carthaginian Hanno round the north-west coast, perhaps to the equator (300 B.C.?), little was done for the seaboard till the 14th century A.D., when the Dieppe mariners claim to have founded 'Little Dieppe' on the Guinea coast (1364), and colonised the Canaries under Jean de Béthencourt, and when Italian navigators had coasted the north-west side as far as Bojador, as clearly shown on Marco Pizzigani's sketch map (1367), now in the Parma library. Our general knowledge of the periphery was nearly completed towards the close of the next century, when Vasco da Gama doubled the Cape and skirted the east coast northwards to Magadosho in 2° N. lat. (1497-98). But long before this, the spread of Islam in the 7th century, followed in the 11th (1050-78) by the tremendous irruption of nomad hordes from South-western Asia, had converted the greater part of the northern plains into an Arab domain, which was revealed to science by the Arab writers of the next ensuing centuries. Thus a fair knowledge was acquired of the geographical, political, and ethnological relations in the three physical zones of Maghreb (Mauritania), the Sahara, and Sudan by the works of Edrisi (12th century), Yakút, Abul-Hassan, and Ibn-Said (13th century), Abul-Feda and Ibn-Batúta (14th century), Makrizi, Leo Africanus, and Ibn-Khaldún (15th century), the true pioneers of African exploration. Then followed three hundred years of comparative inactivity, marked by no serious attempt to penetrate far into the interior, and noted chiefly by the occupation of various points on the coast by the Portuguese, Dutch, and English. The Portuguese established relations with the powerful Bantu states of Congo on the west, and Monomotopa on the south-east side; the Dutch obtained a firm footing in the Hottentot country in the extreme south, while the English were attracted more especially to Guinea and Senegambia (Windham's voyage to Guinea in the 16th century, followed by the journey of Jobson and Thomson, and occupation of Cape Coast in 1664).

But the modern epoch of geographical research, apart from political or commercial considerations, begins properly with James Bruce, who discovered the Abai source of the Blue Nile in 1770, and whose adventures in Abyssinia stimulated the foundation of the African Association (1788), which before the close of the 18th century had already sent out

Ledyard, Lucas, Houghton, and Mungo Park to explore the Niger basin.

In the 19th century, the most various motives co-operated in favour of an extended knowledge of this vast continent. The captains of British cruisers employed to suppress the slave-trade supplied some valuable information; the governors of the colonies and private merchants contributed their share; and enterprising travellers from all sides of the coast endeavoured to strike out paths to the interior. In 1802-5, Lichtenstein travelled in the district north of the Cape of Good Hope, and first furnished information regarding the Bechuana tribe. In 1809 Burckhardt was sent out by the African Society, and his explorations, rich in manifold results, occupied the years 1812-16. To the French we are indebted for much valuable information concerning Morocco, Algeria, and the neighbouring parts of Sahara. The labours of Oudney, Clapperton, Denham, and Lander, in the Sahara and Sudan are memorable by the discovery of Lake Tsad and the course of the Niger. Since about 1840, our knowledge of South Africa has received many important additions from the missionaries stationed there, especially Moffat; while David Livingstone, who from 1843 to 1873 was engaged in trying to open the countries north of the Cape of Good Hope, penetrated in 1849 as far as Lake Ngami, in 20° S. lat.; and in 1853, ascending the Leecambe (Zambesi) northward for several hundred miles, succeeded in crossing the continent to Loanda on the west coast. Having retraced his steps to the point of the Zambesi from which he had started, the adventurous traveller next followed that stream till he reached the east coast, at Quilimane, in 1856. From 1859 to 1863 was spent in various explorations of Lake Nyasa and the neighbouring regions. Again setting out in 1866, he found, in the region south of Lake Tanganyika, the river Chambezi. This river, which is specially known by this name ere it falls into Lake Bemba or Bangweolo, is known between that lake and Lake Moero as the Luapula, and farther on in its course as the Lualaba; and was by Livingstone traced through these lakes and as far as 4° S. lat. Livingstone's belief was that this basin, now known to be the Upper Congo, contained the head-waters of the Nile. In 1871, along with Stanley, he found the river Rusizi flowing into the north of Lake Tanganyika. After some farther exploration of these regions, and new efforts to find the Nile sources, he died at Ilala, beyond Lake Bemba, in May 1873. Burton and Speke, crossing the Border Mountains from Zanzibar, in 1857, discovered Lake Tanganyika; and the latter then journeying to the N.E., discovered the southern part of the great Victoria Nyanza, which he supposed to be the head reservoir of the Nile. A second expedition, undertaken by Speke and Grant in the end of 1860, penetrated as far north as Gondokoro on the White Nile, and added vastly to our knowledge of the eastern equatorial regions of Africa. At Gondokoro, Speke and Grant were met by Sir Samuel Baker, who, accompanied by his heroic wife, pushed on to the south, and discovered in 1864, west of the Victoria, another great lake, which he called the Albert Nyanza. He returned in September 1873 from a second expedition—of a military character—undertaken in 1869, at the expense of the Pasha of Egypt, to suppress slavery in the upper regions of the Nile. The geography, language, and manners of the inhabitants of Abyssinia, Senaar, and Kordofan have also been greatly illustrated by the efforts of various European travellers.

The researches of Dr Barth and his companions (1850-55) and Dr Gustav Nachtigal (1869-74)—

investigating the same central division of the continent as Clapperton and Denham—and Dr Schweinfurth's travels (1868-71) in unexplored regions, have enriched our store of knowledge regarding this land of mystery. In 1874-75 Lieutenant Cameron surveyed the lower half of Lake Tanganyika, and walked across tropical Africa from east to west; while H. M. Stanley, after exploring the Shimiyu, farthest southern head-stream of the Nile, circumnavigated Victoria Nyanza, and discovered a lake, which he took for Albert Nyanza, but which is now known to be Lake Dweru, a small lake communicating (as he himself discovered later) with Lake Edward. Then staking the Lualaba at Nyangwe in the end of 1876, he forced his way down the stream; and arriving at the mouth of the Congo in autumn 1877, demonstrated that the Lualaba and the Congo are identical. In 1877-79 Serpa Pinto crossed from Benguela to Durban in Natal. In 1880 Joseph Thomson explored the route between Nyasa and Tanganyika; and in 1884 he made his memorable journey from Mombasa by Kilima-Njaro and Kenia across Masai Land to the Victoria Nyanza. In 1884 Sir H. H. Johnston camped on Kilima-Njaro, and ascended the main peak to a height of 16,200 feet. Dr G. A. Fischer, in his attempt to relieve Emin Pasha, reached north to Lake Baringo (1885-1886). In 1885 Grenfell discovered the Ubangi, the great northern tributary of the Congo, which he navigated to within 200 miles of the farthest point reached by Dr Junker (22° 40' E. long.), penetrating westward down the Welle-Makua (1886). It was thus made evident that Schweinfurth's Welle flows, not to Lake Tsad through the Shari, but through the Ubangi to the Congo.

In 1887 Emin Pasha reported by letter repeated exploration of the Albert Nyanza (q.v.). Meanwhile Stanley's expedition was on its way by the Congo to rescue him. The intricate water-system south of the Middle Congo was also unravelled, especially by Pogge, Wissmann, and Ludwig Wolf (1881-86), who made it evident that the Kwango, Kassai, Sankuru, and Lake Leopold all belong to one magnificent hydrographic system flowing through the Kwa to the Congo at Kwamouth, and including Livingstone's Kassabi (1854). It was on the Sankuru that Dr Wolf made the acquaintance of the pigmy Batwas, one of the smallest races of mankind. The Ogowe system, first discovered by Du Chaillu (1850), ascended by Walker to Lope (1873), and surveyed by Compègne and Marche to Ivindo (1874), has been completely elucidated by De Brazza, Mizon, and Rouvier during various expeditions between 1877-86. The Alima, supposed to be one of its head-streams, has been followed to the right bank of the Congo; and the Ogowe itself, reported to be one of the great continental basins, proves to be a coast stream of secondary importance. After visiting it in 1874, Dr Oscar Lenz transferred the scene of his operations to the north, crossing from Morocco to Timbuktu in 1880, and doing excellent surveying work on the route across the Western Sahara. The same route had been followed by Chaillié in 1828, himself preceded (1826) by Laing from Tripolitana, and followed by Barth (1853), these besides Mungo Park being the first European travellers that reached Timbuktu during the nineteenth century. Again moving southwards, Lenz ascended the Congo to Nyangwe, and crossed the continent from the mouth of that river to the Zambesi delta in seventeen months (1885-86). He had been preceded by nine expeditions—Livingstone, Loanda to Quilimane, 1854-56; Cameron, Zanzibar to Benguela, 1873-75; Stanley, Zanzibar to Congo mouth, 1874-77; Serpa Pinto, Benguela to Natal, 1877-79; Matteucci and Massari,

Suakin to Niger delta, 1880-81; Wissmann, Loanda to Zanzibar coast, 1881-82; Arnot, Natal to Benguela, 1881-84; Capello and Ivens, Mossamedes to Zambesi delta, 1884-85; Gleeurp, Congo mouth to Zanzibar, 1884-86.

These were all routes from east to west or west to east. The first to traverse Africa from north to south (Holub failed in 1886) were Grogan and Shaip, who described their journey in *From the Cape to Cairo* (1901); and they were soon followed. Meantime, although still numerous, and in some places extensive, the blank spaces on the map of Africa are being rapidly filled up, thanks partly to private enterprise, partly to the activity displayed by the officers in the service of the Belgian Congo. Regions that have comparatively recently been fully or partly explored are (1) the Upper Zambesi and the space between that river and the head-waters of the Congo; (2) the region between the Congo and equatorial lakes; (3) the region between the Congo and Shari basins, and thence westwards to the Bight of Biafra; (4) most of Somáli, Kaffa, and Galla Lands; (5) much of the region enclosed by the great northern curve of the Niger.

See works on Africa by Keith Johnston, Reclus, Hartmann, and others; the works and the lives of Bruce, Mungo Park, Livingstone, Baker, Burton, Speke and Grant, Barth, Schweinfurth, Cameron, Stanley, Johnston, Thomson, and other travellers; Jones's *History of African Exploration* (New York, 1875); books on the partition of Africa amongst the European Powers by Silva White (1892) and Scott Keltie (1893; new ed. 1895); Dr R. Brown's *Story of Africa* (4 vols. 1892-95); 'Africa,' in *Stanford's Compendium*, by A. H. Keane (2 vols, 2nd ed. 1904, 1907); also the articles on SCHNITZER, STANLEY (H. M.), &c., and the various countries.

AFRICANDER, or **AFRIKANDER**, is a term for the descendants of European parents born in South Africa. A prominent political party, having for its object the consolidation and extension of the political influence of the Dutch party in South Africa, was long known as the Afrikaner-Bond, but in 1902 changed its name to the South African Party.

Afrit, a powerful evil genie or demon in Mohammedan mythology.

Afzelius, ADAM, Swedish botanist, born 8th October 1750, became professor of Oriental Languages at Uppsala, and in 1785 demonstrator in Botany there. He visited Sierra Leone in 1792, was for a time secretary of the Swedish Legation in London, and in 1812 became professor of *Materia Medica* at Uppsala, where he died in 1837. As a pupil of Linnæus he edited his autobiography; and he wrote several works on the plants of the Guinea coast.

Ag'ades, once a very important city of Central Africa, and still a great meeting-place of trading caravans, is the capital of the state Air or Asben, south of the Sahara, and is built upon the eastern edge of a great tableland, at an elevation of not less than 2500 feet. In the 16th century it probably contained 60,000 inhabitants; now it has some 7000.

Agadir, the southernmost seaport town in Morocco, lies at the mouth of the Sûs, 23 miles SE. of Cape Ghir. Its harbour is the best on the coast, and it was once a place of importance; but the rise of Mogador greatly damaged its standing, and its pop. is now only some 1200. The descent of a German war-ship here in 1911, while Fez was occupied by French troops, made Agadir the centre of European diplomacy and danger, Germany demanding compensation for allowing France a free hand in Morocco.

Agamemnon, son of King Atreus, and brother of Menelaus. After his father's death, he reigned in Mycenæ, and married Clytæmnestra, by whom he had three children—Iphigenia, Electra, and Orestes.

When Paris, son of the Trojan king, Priam, carried off Helen, the wife of Menelaus, king of Lacedæmon, Agamemnon, with his injured brother, traversed Greece, exhorting all the leaders of the people to unite their forces in an expedition against Troy. Having gained their alliance, Agamemnon was appointed general-in-chief of the united forces assembled at Aulis in Bœotia, where they were delayed some time. In the *Iliad*, which gives an account of the war that followed, Agamemnon is described as a very stately and dignified figure. After the fall of Troy, he returned home, taking with him Cassandra, the daughter of Priam. Shortly afterwards, he was murdered by Clytæmnestra, aided by Ægisthus, in whose care he had left his wife and children. A tragical fate had always lowered over the house of Agamemnon; and the destinies of his children—Iphigenia, Electra, and Orestes—were the favourite subjects of the three great Greek tragedians. See ÆSCHYLUS.

Ag'ami, the common name of a genus of crane-like birds (*Psophia*), better known as Trumpeters (q.v.).

Agamidae, a family of squat-bodied, thick-tongued, terrestrial lizards, closely related to the Iguanas (q.v.). They frequent stony and sandy regions. Some measure a foot in length, but most of them are smaller. The skin is frequently beset with thorny scales. The family is confined to the Old World, and is most abundantly represented in Australia. The Thorn-devil or Moloch of Australia, the 'Flying Dragon' (*Draco volans*) of Indo-Malayan countries, the common Agama of Egypt (*Agama stellio*), and the Dabb of the Arabs (*Uromastix spinipes*) are well-known representatives.

Agamogenesis, reproduction without sex, a process of multiplication by division, budding, &c., in which there is no union of sexual elements, but simply more or less discontinuous growth. It is exceedingly common among the lower animals and in plants, but is gradually replaced in the higher by the more specialised method of sexual reproduction. See PARTHENOGENESIS, REPRODUCTION, SEX.

Agapæ (Gr. *agapê*, 'love') were love-feasts, or feasts of charity, originally celebrated by the early Christians in connection with the Lord's Supper. Wealthy or well-to-do Christians brought the materials of the feast, in which the poorer brethren who had nothing to bring shared equally. Prayers were said, hymns sung, and church business discussed; and the meetings closed with the 'holy kiss.' The agapæ long maintained something of the early Christian community of goods. Both the Lord's Supper and agapæ were at first celebrated in the evening; but during the persecutions, when the Christians had often to hold divine service before dawn, the Lord's Supper followed the morning service. Later, a formal separation was made between the two rites. In the 3d and 4th centuries, the agapæ had degenerated into a common banquet, where the deaths of relatives and the anniversaries of the martyrs were commemorated; and they ultimately became occasions of debauchery, or were suspected to be so by the heathen. Councils declared against them, forbade the clergy to take any share in their celebration, and finally banished them from the church. Some Protestant sects have instituted a kind of agapæ, tea-meetings with praise and prayer.

Agapem'oné (Gr., 'love-abode'), a community of religious visionaries founded in 1859 at Charlinch, near Bridgewater, Somersetshire, by Henry James Prince, previously a clergyman of the Church of England. It is described in Hepworth Dixon's *Spiritual Wives* (1868).

Agar, a town of India, in the state of Gwalior, 41 miles N.E. of Ujain. It stands in an open plain, 1765 feet above the sea. Pop. 5700.

Agar-agar, the dried sliced stem of a seaweed, used in cookery under the name of Bengal or Japan isinglass. It resembles gelatine, but when made into jelly is less easily liquefied by heat, and is therefore much employed in the cultivation of microscopic fungi. See BACTERIA, GERM THEORY.

Agardh, KARL ADOLF, a Swedish botanist, was born 23d January 1785, studied at Lund, and in 1812 became professor of Botany there. He subsequently took orders, and died a bishop in 1859. In several great works on the algæ, he laid the foundations of our present knowledge of these plants; and he wrote also on economics.—His son, JAKOB GEORG, born 1813, became his successor in the chair at Lund (1854–1879), and continued his labours on the algae in a series of important works.

Agaric and Agaricus. See MUSHROOM.

Agassiz, JEAN LOUIS RODOLPHE, one of the most eminent naturalists of his time, anti-Darwinian, and assertor of 'centres of creation,' was born at the village of Motier, in the canton of Fribourg, Switzerland, 28th May 1807. At ten years of age he was placed at a college for boys at Bienne, preparatory, as was then understood, to entering upon a mercantile life; but so marked an aptitude for the pursuit of natural history was manifested during his course here, that he was permitted to continue his studies at Lausanne and Zürich, and afterwards at the universities of Heidelberg and Munich, graduating in medicine at the latter institution in 1830.

Prior to his graduation, he prepared a description of the *Fishes of Brazil* (from specimens gathered by Spix, under the patronage of the king of Bavaria), which elicited a warm encomium from Cuvier, with whom he was afterwards associated on terms of intimacy. Near the close of 1831 he repaired to Paris to pursue his investigations at the Museum of Natural History, where, receiving some pecuniary assistance from Baron Humboldt, he was enabled to remain until the autumn of 1832, when he accepted a professorship at Neuchâtel. In 1833 he commenced the publication of his *Researches on the Fossil Fishes*, which the following year brought him from London the Wollaston prize. In 1834 he visited England for the first time, where he was warmly welcomed, and in 1836 commenced an examination of the glacial phenomena of the Alps, his theory of which subsequently found expression in his *Études sur les Glaciers* (1840), and in his *Système Glaciaire* (1847). In 1839 he published a *Natural History of the Fresh-water Fishes of Central Europe*.

In the summer of 1840 Agassiz established a station of observation on the Alps (where, with a corps of assistants, he spent each summer until 1844), and in the following autumn he visited the Scottish Highlands, with gratifying results, for additional evidence in support of his glacial theory.

In October 1846 Agassiz went to America, and delivered in Boston a course of lectures *On the Plan of the Creation*. These at once established his reputation as a popular lecturer, and during the winters of 1847 and 1848 he lectured in the principal cities of the United States, everywhere with success. In 1848 he was elected to the chair of Natural History in the Lawrence Scientific School at Harvard University, and in the summer of that year, in company with a class of students, made a scientific expedition to the northern shores of Lake Superior. At the invitation of Professor Bache, Superintendent of the United States Coast Survey, he spent the winter of 1850–51 in an

expedition to the Florida Reefs, his report upon which was afterwards published in the *Memoirs of the Museum of Comparative Zoology*. In 1851, in addition to his work at Cambridge, he accepted a professorship at the Medical College of Charleston, South Carolina, where he spent the following winter, and in the spring delivered a course of lectures at Washington, before the Smithsonian Institution, of which he was soon appointed a Regent. In 1854 he was invited to a chair in the university of Zürich, Switzerland, which he declined, and the following year, assisted by his daughters, he established at Cambridge a young ladies' school, which was continued for eight years, until closed in consequence of the civil war. Meanwhile, Agassiz had planned an important work, *Contributions to the Natural History of the United States*, of which he lived to issue four 4to vols. He declined a chair of Palæontology at Paris in 1857, but received the Order of the Legion of Honour. In 1858 he gave all his collections (worth \$10,000) to the Museum of Comparative Zoology at Harvard. Many of his views were in advance of those commonly held, and contradicted established theological tenets; he did not adhere to the 'special creation' theory, but was 'polygenist' on the question of the origin of man (see ETHNOLOGY). But he could not accept the Darwinian theory of evolution, earnestly controverted it, and was distressed that most of his own disciples became converts to it. A trip to Brazil, primarily for the benefit of his health, developed into one of the most important scientific expeditions of Agassiz's whole life. After an absence of sixteen months, he returned to the United States, the account of his trip, as prepared by his wife, being published under the title of *A Journey in Brazil*. In 1872 he visited California, and next year received for a summer school of Natural History a gift of the island of Penikese in Buzzard's Bay, on the Massachusetts coast, and a money endowment of \$50,000. He was organising this unique school when he died, December 14, 1873. He was usually known simply as Louis Agassiz.

See the *Life and Correspondence*, edited by his wife (1886), the monograph by Holden (1893), and the *Life, Letters, and Works*, by Marcou (1896).

His son, ALEXANDER, author of *Contributions to American Thalassography* (1835–1910), was born at Neuchâtel in Switzerland, joined his father at Boston in 1849, graduated at Harvard, and was an assistant in the Harvard Museum in 1860–65. Applying his special training in geology, chemistry, and engineering, he made a fortune in the copper-mines of Lake Superior, but became curator of the Harvard Museum on his father's death in 1873, retiring in 1897. He did much deep-sea dredging; founded the zoological station at Newport, Rhode Island; and wrote on his dredging cruises, on oceanography, on coral formations, and on the embryology of the star-fishes, the flounders, and the ctenophora. He had the Legion of Honour and the Prussian Order of Merit. Like his father, he greatly enriched and extended the Harvard Museum. See his *Letters and Recollections* (1913).

Ag'ate, a mineral composed of layers of quartz, generally of different varieties of colours, intimately joined together. It usually occurs as rounded nodules or veins in trap rock. The layers are often concentric, and in the section sometimes appear nearly circular. The composition varies greatly, but silica is always predominant, usually with alumina and oxide of iron. Chalcedony (q.v.) carnelian, amethyst, common quartz, jasper, opal, and flint occur as layers in agate, and are spoken of as kinds of agate. There are also clouded agates, s'ar-agates, moss-agates, &c., so called from their

appearance. It takes a fine polish, and is much used for ornamental purposes. Many agates are found in Scotland, and are sold under the name of *Scotch Pebbles*.

Ag'atha, ST, a noble Sicilian lady of great beauty, who rejected the love of the Prefect Quintilianus, and suffered a cruel martyrdom in the persecution of Christians under Decius (251). She holds a high rank among the saints of the Roman Catholic Church; her festival falls February 5.

Agathangelus, AGATHANGE or AKATHANGELOS, Armenian historian, lived during the 4th century, and wrote a history which, as now known, treats of the life and doctrine of St Gregory the Illuminator, and of the conversion of Armenia to Christianity. See Langlois, *Collection des historiens de l'Arménie* (vol. i. 1867).

Agatharchus, Athenian painter of the 5th century B.C., said by Vitruvius to have been the first to paint a scene for the acting of tragedies. On that account, however, he did not, as has been held by some, introduce perspective and illusion.

Agathias (c. 536-82), Greek poet and historian, was educated at Alexandria and Constantinople, and practised as an advocate. He wrote love verses, and made an anthology. But his most valuable work is his history of his own time, a continuation of Procopius and the chief authority for the period 552-58.

Agath'ocles, Tyrant of Syracuse, was born at Therinæ, in Sicily, in 361 B.C. As leader of the popular party in Syracuse, he was twice driven into exile, but ultimately made himself autocrat of Syracuse, after a massacre of several thousands of citizens, 317 B.C. Having failed in an attempt to expel the Carthaginians from Sicily, he passed over to Africa, and attacked them there. This war he carried on with success for four years, or until 307 B.C., when he suffered a serious defeat, and basely abandoning his troops to the enemy, escaped safely into Sicily. There, by fraud and bloodshed, he soon recovered his former power; but in 289 B.C. one of his favourites destroyed him by means of a poisoned toothpick.

Agathon (c. 448-400 B.C.), Athenian tragic poet, the friend of Euripides and Plato. After Æschylus, Sophocles, and Euripides, he holds a position of first importance. In his plays he introduced various innovations, as, in his *Anthos*, the use of an invented in place of a borrowed mythological plot. He is mentioned by Plato (*Symposium*) and ridiculed by Aristophanes (*Thesmophoriazusæ*). He survives only in fragments.

Agavé, a genus of plants of remarkable and beautiful appearance, belonging to the natural order Amaryllidæ (q.v.). There are a number of species, all natives of Mexico and Central America. They are often popularly confounded with Aloes (q.v.); and *Agave americana* is generally known by the name of American Aloe. The agaves have either no proper stem, or a very short one bearing at its summit a crowded head of large, fleshy leaves, which are spiny at the margin. From the midst of these shoots up the straight, upright scape, 24 to 36 feet high, and at the base often 1 foot in diameter, along which are small, appressed, lanceolate bractæ, with a terminal panicle, often bearing as many as 4000 flowers. In Mexico, these plants usually flower in the seventh or eighth, sometimes even fifth or sixth year, and even in poor soils or exposed situations seldom later than the twelfth year, but in our hothouses not until they have reached a very advanced age (80-100 years); whence arises the gardeners' fable of their flowering only once in one hundred years. After flowering, the plant always dies down to the ground, but new

plants arise from lateral buds. The best known species is *Agave americana*, which was first brought to Spain in 1561, and has become naturalised in Naples, Sicily, Greece, and the north of Africa. By maceration of the leaves, which are 5 to 7 feet long, are obtained coarse fibres, which are used under the name of *maquay*, for the manufacture of thread, twine, ropes, hammocks, &c. This fibre (also known as Pita Flax) is now produced to some extent in the south of Europe. It is not very strong or durable, and if exposed to moisture it soon decays. The ancient Mexicans employed it for the preparation of a coarse kind of paper, and the Indians use it for oakum. The leaves, cut into slices, are used for feeding cattle. When the young flower-bud has been cut out, the sap continues to flow into the cavity for a considerable time. This is termed *aguamiel*, and contains a considerable amount of sugar. It is collected daily, and after rapid fermentation furnishes the national beverage called *pulque*. This is milky, sour, and ill-smelling, resembling thin buttermilk, and strongly recalling the flavour of rotten eggs. In large quantities it produces a dull intoxication followed by heavy sleep. The strong spirit of the country (*aguardiente* or *mescal*) is also distilled from it. *Agave americana*, *Agave mexicana*, and other species are extensively cultivated for these purposes. The valuable Sisal-hemp is produced by *A. sisalana* (see FIBROUS SUBSTANCES).

Agde, an ancient French town in the department of Hérault, situated about 3 miles from the Mediterranean Sea, on the left bank of a navigable stream, the mouth of which forms a harbour. It has a brisk coast-trade, while it is also the entrepôt for the traffic of the south and west of France. It stands on the lava from an extinct volcano, and is the ancient *Agatha Narbonensis*, originally a Greek colony. Pop. 9000.

Age is used specially to denote certain long periods in the history of the human race or of human civilisation. The idea of a succession of ages presented itself at a very early period to the Greek mind. The life of the race was likened to that of the individual—hence the infancy of the race might easily be imagined to be the most beautiful and serene of all. Hesiod mentions five ages—the golden, simple and patriarchal; the silver, voluptuous and godless; the brazen, warlike, wild, and violent; the heroic, an aspiration towards the better; the iron, in which justice, piety, and faithfulness had vanished from the earth, the time in which Hesiod fancied that he himself lived. Ovid imitates him, but omits the heroic age. This idea, at first perhaps a mere poetic comparison, gradually worked its way into prose. These ages were regarded as the divisions of the great world-year, which would be completed when the stars and planets had performed a revolution round the heavens, after which destiny would repeat itself in the same series of events. The golden age was said to be governed by Saturn; the silver, by Jupiter; the brazen, by Neptune; and the iron, by Pluto. The geological ages or periods will be found discussed at GEOLOGY; while the stone, bronze, and iron ages which archaeological research accepts, are treated at ARCHÆOLOGY. The *Middle Ages* have been so called as intervening between classical antiquity and modern times. The *Dark Ages*, nearly coinciding in time with the middle ages, refer to the period of intellectual darkness from the decline of classical learning, after the establishment of the barbarians in Europe in the 5th century, till the Renaissance (q.v.) in the 15th century. Modern philosophical speculation has also attempted to divide human history into definite ages or periods.

Fichte numbers five, of which he conceives that we are in the third; Hegel (q.v.) and Auguste Comte reckon three (see POSITIVISM). The word Age is also very familiar in such phrases as the Augustan Age, the Elizabethan Age, &c. In the life of an individual, it is usual to speak of four ages—infancy, youth, manhood, and old age; though some physiologists (like Shakespeare in *As You Like It*) count seven—infancy, childhood, boyhood or girlhood, adolescence, manhood or womanhood, age, and old age. See LONGEVITY.

Age. The legal divisions of human life differ considerably in different countries. In England the whole period previous to twenty-one years of age is usually spoken of as *infancy*, a term which has a totally different signification in those countries that have followed the civil law. The condition of infancy in English law, however, is not one of uniform incapacity throughout or for all purposes. Thus the marriages of boys over fourteen and girls over twelve, if duly celebrated, are valid. Infancy, generally, is for the protection of civil rights. By a statute of 1874 it is declared that contracts for the loan of money and supply of goods to infants, and 'accounts stated' with infants, are void. But contracts entered into by infants for necessities are valid. An infant committing a wrongful act to the injury of another is liable to an action of tort. He cannot make a will unless he is a soldier on active service or a mariner at sea. He cannot bring or defend an action without the assistance of an adult. In criminal law a child under seven years is incapable of felony, and up to the age of fourteen there is a presumption against the existence of a criminal mind and intention; but infants between fourteen and twenty-one are fully responsible for criminal acts. Modern legislation has made special provision for the trial and punishment of children under sixteen.

By the law of Scotland, again, life is divided into three periods—*pupilarity*, *minority*, and *majority*. The first extends from birth to the age of legal puberty, which is fourteen in males and twelve in females, at which ages they may respectively marry; the second embraces the period from the termination of pupilarity till the attainment of majority, which takes place at the age of twenty-one in both sexes; and the third includes the whole of after-life. The office of *tutary* corresponds in duration to pupilarity, that of *curatory* to minority (see TUTOR, GUARDIAN). By the intervention of a tutor or curator contracts may be made binding on a person who is not of full age. In Scotland a minor can dispose of his movable estate by testament. The rules as to the criminal responsibility of young persons are similar to those prevailing in England. In France the marriageable age is eighteen in males, and fifteen in females, an arrangement more reasonable than that which we have borrowed from the Romans, which, however suitable it may have been to the climate of Italy, could never have been free from inconveniences in this country. Twenty-one is generally the age at which men are eligible for public offices; and at this age they may elect, and be elected, members of parliament. But a man must be twenty-four before he can be admitted to priests' orders in the English Church, and thirty before he can be a bishop.

In the United States full age is the day preceding the twenty-first anniversary of a person's birth. All persons under seven years of age are incapable of crime; and between the ages of seven and fourteen the legal presumption is they are not capable of crime, but this assumption may be rebutted by strong and clear proof of a mischievous discretion or knowledge of the wrong. The presumptions of innocence cease at the age of fourteen, at which times males may choose their own guardian, and at

eighteen may enlist in the army. Females are supposed to arrive at discretion at twelve years of age, and may consent to marriage, and at fourteen choose their own guardian. In some of the states they become of full age at eighteen. A male may vote at twenty-one, be elected a representative to congress at twenty-five, and a senator of the United States at thirty.

The legal disabilities attaching to the different stages of minority, or, to speak more correctly, the privileges which the law confers on minors for their protection, will be treated of under the different subjects to which they relate (see CONSENT, CONTRACT, CRIME, GUARDIAN, INFANT, MARRIAGE). The ascertainment of age is an interesting problem in medical jurisprudence. The most reliable evidence afforded by the skeleton is that connected with the teeth, the skull, and the general character of the bony attachments.

Agen, the chief town of the French department of Lot-et-Garonne, situated in a fertile region on the right bank of the Garonne, 84 miles SE. of Bordeaux, is old and gloomy in appearance; it carries on an active trade in woollen and linen fabrics, leather, coloured paper, colours, cordage, sail-cloth, fruits, vegetables, and tobacco, and is an important railway centre. Agen (*Aginnum*) was the capital of the Keltic tribe of Nitobroges, as it was later of the province of Agenais. There are extensive remains of the Roman town. The bishopric of Agen was founded in the 4th century. The cathedral dates in part from the 12th century. In Agen Joseph Scaliger and the poet Jasmin were born. It often suffered the miseries of war at the hands of Goths, Huns, English, and Huguenots. Pop. 23,000.

Agenais, a former province of France, long in the possession of the kings of England, now forms most of the department of Lot-et-Garonne. The capital was Agen (q.v.).

Agence Havas. See HAVAS AGENCY.

Agent is one who is authorised or delegated to transact business for another (who in this relation is called his principal or constituent) in whose place he comes, and who is bound by his acts in the business to which the agency extends. In Roman law this was the gratuitous contract of mandate, but the modern factor almost invariably works for hire. Even where gratuitous, the mandatary is of course bound to account for his introductions, and entitled to do what is necessary for executing his instructions, and to reimbursement of his advances and relief of his engagements. The appointment of an agent may be either express or implied; but if the agent is to execute deeds in the name of his principal, he must be appointed under seal by a formal document known as a 'power of attorney.' The authority of an agent depends on the scope of his employment. The most common kinds of special agents are brokers, stockbrokers, ship-brokers, insurance-brokers, supercargoes, ship's-husbands, procurators to draw or accept bills, wharfingers, travellers or riders, bank-agents, and law-agents. Of all these the powers and liabilities are fairly well fixed by mercantile custom and understanding, or in some cases by a written authority which is exhibited.

Third parties dealing with an agent are not concerned with unusual restrictions, unknown to them, placed upon his authority. The agent is bound to carry out with care the instructions given. He is not liable for the solvency of customers, unless he has accepted a *del credere* commission. He must obtain the consent of his principal to his dealings on his own account in the business of the agency. His remittances should be through a bank of good reputation, and if he pays into his own account he is liable for the amount. If the principal is named,

or otherwise known, *prima facie* the agent undertakes no liability to the customer. If the principal's existence is undisclosed, the other contracting party, on discovering it, has an option whether he will hold agent or principal liable. Principals are generally liable for the fraud and misrepresentation of an agent committed in the line of the business. A mercantile agent who, with the consent of the owner, is in possession of goods or of the documents of title to goods, has, by statute, an implied authority to sell or pledge the goods. Any secret profit received by the agent must be accounted for and paid over to the principal. Under the Prevention of Corruption Act, 1906, an agent who corruptly accepts any gift or consideration for doing, or forbearing to do, any act in relation to his principal's affairs is guilty of a misdemeanour.

In the United States an agency may be created by deed, in writing not by deed, or by verbal delegation of authority. It may be implied from the relation and acts of the parties and the nature of the employment, without any express appointment. When the authority extends to all acts connected with a particular business it is called *general*, but when confined to a single act it is called *special*. The agency may terminate by revocation of the power conferred. A person cannot act as agent in a transaction wherein he has an adverse interest or employment. The death of either principal or agent terminates the agency.—For the duties of consular and diplomatic agents, see CONSUL, DIPLOMACY.

Agent and Client. The employer of a law-agent is entitled to presume that he is possessed of competent professional knowledge, and the agent is consequently responsible to his client for the consequences of want of reasonable care and skill, or gross ignorance in the conduct of the business entrusted to him, as in not duly negotiating a bill, using a wrong stamp, taking an informal security. He does not guarantee that his advice shall be correct. A law-agent is not entitled to receive a gift from his client, or to make gain for himself at the expense of his client over and above his professional fees. He has a lien over title-deeds and other documents in his possession belonging to the client. See SOLICITOR, WRITER TO THE SIGNET.

Agent-general is the representative in London of Newfoundland, of a Canadian province, or of an Australian state.

Ageratum, a tropical American genus of Compositæ (Tubulifloræ) akin to hemp agrimony, with about thirty species. Some, with white or lavender-blue flower-heads, are used for summer bedding in garden borders. *A. conyzoides* is an exceedingly common weed in Ceylon and other tropical countries.

Agesilaus, king of Sparta (397-360 B.C.), was elevated to the throne chiefly by the exertions of Lysander. He was one of the most brilliant soldiers of antiquity. Being called upon by the Ionians to assist them against Artaxerxes, he commenced a splendid campaign in Asia; but was compelled by the Corinthian war, in which several of the Grecian states were allied against Sparta, to leave his conquest over the Persians incomplete, and return to Greece. At Coronæa (394 B.C.), he gained a victory over the allied forces, and in 378 the war was concluded by a treaty of peace in favour of Sparta. Afterwards, in the Theban war, though hard pressed by Pelopidas and Epaminondas, and defeated at Mantinea (362), he bravely and ably defended his country. He fought a campaign in Egypt, and returning, he died in his 84th year.

Agglomerate, or VOLCANIC AGGLOMERATE, is a rock made up of a confused mass of angular and subangular blocks of all sizes. The blocks

may consist exclusively of igneous rocks, or of sedimentary rocks, or of both, set in a more or less meagre matrix of finer-grained detritus of the same materials. The rock is of volcanic origin, and is frequently found in Scotland filling up vertical holes or pipes which seem to have been the throats or necks of ancient volcanoes.

Agglutinative Language. See PHILOLOGY.

Aghrim, a hill in Galway, Ireland, 30 miles SW. of Athlone. Here, on 12th July 1691, Ginkell defeated the French and Irish adherents of James II. under St Ruth.

Agincourt, now AZINCOURT, a small village in the centre of the French department of Pas-de-Calais, celebrated for a bloody battle between the English and French, October 25, 1415. The internal distractions of France under the imbecile Charles VI. had encouraged England to attempt to make good her ancient claims. Henry V. of England had landed at Harfleur, had taken that fortress, and was marching to Calais, in order to go into winter-quarters. But a French army, vastly superior in number, intercepted the English march to Calais, near the village of Agincourt. The invading army, weakened in numbers and suffering from want of provisions, was still 14,000 strong; the French, under the Constable D'Albret, numbered 50,000 or more. The battle lasted three hours, and was a signal victory for the English, due mainly to the archers. As many as 10,000 Frenchmen are said to have fallen, among whom were the Constable, three dukes, and ninety barons. Five princes, among them the Dukes of Orleans and Bourbon, were taken prisoners. The English lost 1600 killed.

Agio, an Italian word, is used, generally in connection with continental exchanges, to denote the difference between the real and the nominal value of money, or between coin and paper money; also the variations from fixed pars or rates of exchange. It sometimes also corresponds very nearly to the English word 'premium.' See EXCHANGE.

Agis, the name of several kings of Sparta, of whom the most noted was Agis IV. He came to the throne in 244 B.C., when the state of Sparta had fallen into a ruinous condition through long-continued war. The riches of the state were in the hands of a few persons, while a great majority of the people were in extreme indigence. Agis, therefore, in accordance with the old laws of the state, proposed the increase of the number of citizens by the admission of a certain number of Helots and aliens, to be followed by the redistribution of landed estates by lottery. But insuperable difficulties were thrown in the way; the people were persuaded that his schemes were inimical to the welfare of the state; and Agis was put to death by strangulation (241 B.C.).

Agna'no, till 1870 a small lake 3 miles west of Naples, about 60 feet in depth, and without visible outlet. As it caused malaria, it has been drained. The surrounding country is volcanic and mountainous. On the right lies the *Grotta del Cane* (q.v.), and on the left are found the sulphurous vapour-baths of *San Germano*.

Agnate (Lat. *agnatus*). Agnates, in the law both of England and Scotland, are persons related through the father, as cognates are persons related through the mother. In the Roman law, both of these terms had a somewhat different signification. Agnates, by that system, were persons related through males only, whilst cognates were all those in whose connection, though on the father's side, one or more female links intervened. Thus, a brother's son was his uncle's agnate, because the

propinquity was wholly by males; a sister's son was his cognate, because a female was interposed in that relationship. With us the intervention of females is immaterial, provided the connection be on the male, or paternal, side of the house. The cause of our having thus changed the meaning of terms manifestly borrowed from the Roman law, seems to be that in Rome the distinction between agnates and cognates was founded on an institution which has not been adopted in the Roman sense by any modern nation—that, namely, of the *Patria potestas* (q.v.). Roman agnati are defined by Hugo to be all those who either were actually under the same *paterfamilias*, or would have been so had he been alive; and thus it was that, as no one could belong to two different families at the same time, the agnation to the original family was destroyed, and a new agnation created, not only by marriage in the case of a woman, but by Adoption (q.v.). The foundation of cognation was relationship by blood. As persons descended from a common parent were *cognati*, the term *cognatus*, generally speaking, comprehended *agnatus*. But though an agnatus was thus almost always a cognatus, a cognatus was an agnatus only when his relationship by blood was traceable through males. Justinian abolished the distinction between agnates and cognates as regards the law of succession. In the United States the word *agnate* is obsolete, the distinction between the male and female lines of descent not being recognised. See SUCCESSION, GUARDIAN.

Agnes, St., according to legend, was a beautiful Roman Christian in the time of Diocletian, who, having in her thirteenth year refused the heathen son of the prætor, was exposed in a public brothel. The miraculous growth of her hair, the blinding of the prætor's son, his restoration to sight, and the refusal of the flames to touch her—all could not save her from the executioner's sword. Her festival falls on January 21, and her symbol is a lamb. See PALLIUM.

Agnesi, MARIA GAETANA, a woman remarkable for her varied attainments, was born at Milan in 1718. In her ninth year she could converse in Latin, and soon acquired a mastery of Greek, Hebrew, French, Spanish, and German. Her father invited parties of learned men to his house, with whom, in spite of her retiring disposition, Maria disputed on philosophical points. Of her discourses on these occasions, her father published specimens, called *Propositioes Philosophice* (1738). After her twentieth year, she devoted herself to the study of mathematics, wrote an unpublished treatise on Conic Sections, and published her *Istituzioni Analitiche* (1748). The latter was a work of permanent value, and was translated into French and English. When her father was disabled by infirmity, she took his place as professor of Mathematics in the university of Bologna, by the appointment of Pope Benedict XIV. After her father's death in 1752, she made theology her study, and ultimately entered a convent at Milan, where in 1799 she died at the good old age of 81.

Agni, Indian god of fire. See INDIA (*Religions*).

Agnoné, a town of South Italy, 22 miles NW. of Campobasso. It is noted for its copper and steel manufactures. Pop. 10,000.

Agnosticism, a word introduced into the English language by Professor Huxley, in 1869. The term was suggested to him by the inscription, *Agnōstō Theō* ('To an Unknown God'), which the apostle Paul saw on an Athenian altar, as recorded in Acts, xvii. 23. It connotes the doctrine that man does not know anything about spiritual existences, whether divine or human, or about a future life. The advocates

of agnosticism employ two methods of argumentation in support of their position—viz. the *sceptical* and the *critical*. In their reasoning against spiritualism, they are careful to guard themselves against the charge of positive Atheism (q.v.) on the one hand, and of philosophical Materialism (q.v.) on the other. They frankly admit that there is more than matter and force in the universe. The phenomena of consciousness and mental activity cannot, they grant, be put in the same category with the properties of matter. With the former, they admit, physical science cannot deal. 'The passage,' says Professor Tyndall, 'from the physics of the brain to the corresponding facts of consciousness is unthinkable.' Consciousness, they assert, is a function of the brain, as motion is a function of the muscles. As to *how* the stimulation of a sensory nerve gives rise to consciousness, or the stimulation of a motor nerve to muscular contraction, they avow blank ignorance. *Perhaps*, they say, consciousness inheres in a substance other than material; and *perhaps* the series of conscious states, at present associated with man's material organism, may continue to exist apart from it; but these things they do not profess to know. As regards the existence of a God, they say that, having regard to the universality of the law of causation, they cannot refuse to admit an eternal existence, and that, in view of the doctrine of the conservation of energy, they must also grant the *possibility* of an eternal energy. Further, if the existence of immaterial phenomena in the form of consciousness is admitted, an eternal series of such phenomena must be regarded as *possible*. Thus, an eternal existence possessed of consciousness and energy *may be* the First Cause of all things. Agnosticism, however, leaves it an open question whether energy is eternal *a parte ante*; and as to consciousness it maintains that there is no positive evidence that the first cause possesses it at all. The only thing certain, accordingly, is that an eternal existence of some sort must be postulated. Though their belief in the universality of the law of causation shuts them in to this positive conclusion, at the same time agnostics are careful to state that causation cannot be proved by any amount of experience—thus following Hume and Kant, who taught that our only knowledge is of phenomena or sequences. 'The only meaning,' says Professor Huxley, 'of the law of causation in the physical world, is that it generalises universal experience of the order of the world; and if experience shows [and he says it does] a similar order to obtain among states of consciousness, the law of causation will properly express that order' (*Life of Hume*, pp. 184-5). 'Universal experience' of the 'order' of phenomena is, according to this statement, all that is meant by the law of causation. Why phenomena fall into this order, the agnostic does not profess to know. This being so, it follows that, as it is only in consciousness we apprehend phenomena, agnosticism leaves it problematical whether an external world exists at all. *Perhaps* the Idealism of Berkeley (q.v.) is the soundest philosophy. Or, linking human consciousness to a possible eternal series of conscious states, it *may be* that the Pantheism of Spinoza (q.v.) is the most satisfactory solution of the mystery of existence. Owing to the reverence of agnostics for the law of causation, they repudiate free-will. Agnosticism may be regarded as Positivism without its dogmatism. See MANSEL, POSITIVISM, RELATIVITY OF KNOWLEDGE, SPENCER; Sir Leslie Stephen's *Agnostic's Apology* (1893), Professor Flint's *Agnosticism* (1903).

Agnus Dei (Lat., 'Lamb of God'), a title of Christ; also the name given to a prayer in the Mass beginning with these two words. In the musical

reference it is the sixth or last section of the Mass. The figure of a lamb bearing a cross, stamped upon a disc of wax, silver, or gold, as a symbol of Christ, is also styled an Agnus Dei. Such medals have been consecrated by the popes, in certain years of their pontificate, since the 14th century, for distribution among the faithful at Easter, and were worn as amulets.

Agonic Line, the line of no magnetic variation, is an irregular line passing through the magnetic poles of the earth, along which the magnetic needle points directly north or south; see MAGNETISM.

Ag'ora, the public square and market-place of an ancient Greek town, corresponding to the *forum* of the Romans, the scene of public meetings for social or political purposes. The name was also applied to the general assemblies of the people.

Agouti, MARIE DE FLAVIGNY, COMTESSE D' (1805-76), a French author known under the literary pseudonym of 'Daniel Stern,' was born at Frankfurt, and educated at a convent in Paris. She married the Comte d'Agouti in 1827, but left him and formed a connection with Liszt. To him she bore three daughters, the eldest of whom married Emile Ollivier; the second, Guy de Charnace; and the third, first Hans von Bulow, and afterwards Richard Wagner. Amongst 'Daniel Stern's' works are the half-autobiographic romance *Nélida*, *Lettres Républicaines*, *Histoire de la Révolution de 1848*, and *Mes Souvenirs, 1806-33*. Her *Esquisses morales* (1849) is admittedly her best work. Spite of her moral laxity, her *salon* was frequented by such men as Alfred de Vigny and Sainte-Beuve; but when, after 1848, she joined the ultra-democratic party, their place was taken by Lamartine, Enfantin, and Louis Blanc.

Agouti (*Dasyprocta agouti*), a small South American rodent allied to the guinea-pig. The colour of its coarse hair varies from brown to yellow; the form is compact; the legs are slender and pig-like, with three toes on the hind-feet; the ears small and rounded; the tail rudimentary. The agouti lives in the forests of Guiana, Brazil, and Peru, is a gregarious animal, and makes its home at the foot of trees. It is active and agile in its habits, and, usually at night, uttering a grunting cry, wanders in search of food into the plains, where it does much damage to sugar plantations. In Guiana and the West Indies this form is represented by Azara's agouti (*D. azarae*), and by a smaller form, the acouchy. The black-and-yellow rumped kinds are also West Indian, and are very well known. Darwin in *A Naturalist's Voyage* gives the name to the Patagonian cavy. Several species known as 'pampas hares' are hunted as game in southern Brazil and the regions to the south.

Agra, capital of a province, one of the United Provinces of Agra and Oudh, on the right bank of the Jumna, 139 miles SE. of Delhi by rail, and 841 NW. of Calcutta. The ancient walls of the city embraced an area of about 11 sq. m., of which about one-half is now occupied. The houses are for the most part built of red sandstone, and, on the whole, Agra is the handsomest city in Upper India. Some of the public buildings, monuments of the house of Timur, are on a scale of striking magnificence. Among these are the fortress built by Akbar, within the walls of which are the palace and audience-hall of Shah

Jehan, the Moti Masjid or Pearl Mosque, and the Jama Masjid or Great Mosque. Still more celebrated is the Taj Mahal, situated without the city, about a mile to the east of the fort. This extraordinary and beautiful mausoleum was built by the Emperor Shah Jehan for himself and his favourite wife, who died in 1629; and 20,000 men were employed incessantly on it for twenty-two years. The complexity and grace of the general design, and the elaborate perfection of the workmanship, are alike remarkable. The main features of the building are the mausoleum in the centre, on a raised platform, surmounted by a beautiful dome, with smaller domes at each corner, and four graceful minarets (133 feet high). The principal parts of the building are constructed of white marble; and the mosaic-work of the interior is singularly rich and beautiful. British edifices are the Government House, the Government College, three missionary colleges, the Eng-

The Taj Mahal.
From a photograph by Fitts.

lish church, and the barracks. There is trade in cotton, tobacco, salt, grain, and sugar, and manufactures of shoes, pipe-stems, and gold lace, and of inlaid mosaic-work. Pop. (1901) 188,300; (1921) 185,946, of whom about 50,000 are Mohammedans.

This city is held in great veneration by the Hindus, as the scene of an incarnation of Vishnu. Till Aurungzebe removed to Delhi in 1658, it was the capital of the Mogul sovereigns. It was taken in 1784 by Sindhia, and surrendered in 1803 to Lord Lake. From 1835 till 1862 Agra was the seat of government for the North-west Provinces. In June 1857 the Europeans had to retire to the Fort or Residency, but Agra was relieved early in October. Sikandia is a suburb.

Agra and Oudh, THE UNITED PROVINCES OF, a governorship (by Act of 1919) of British India, called 'the North-western Provinces' till the constitution of a new North-west Frontier Province beyond them in 1911, extends from Bengal to the Punjab, lies in the upper basin of the Ganges and Jumna, and constitutes a great part of Hindustan proper. It is an alluvial plain sloping from the Himalayas, and comprises the great wheat country. The headquarters of Hinduism, it contains some of the most sacred memorials of the Aryan race, but was long subject to Moslem sway; some 13 per cent of the population are Mohammedans. The divisions are

Meerut, Agra, Gorakhpur, Kumaun, Rohilkhand, Allahabad, Benares, and (for Oudh) Lucknow and Fyzabad. Area, 107,164 sq. m.; pop. (1901) 47,692,277; (1921) 45,590,946, besides native states with an area of 5000 sq. m., and a pop. of 1,135,000. The capital is Allahabad. See INDIA, OUDH.

Agram (Croatian, *Zagreb*), formerly capital of the province of Croatia and Slavonia, in the Hungarian division of the Austro-Hungarian monarchy, since 1918 a town of Yugoslavia, lies at the foot of a richly wooded range of mountains, 2 miles from the Save, and 142 miles NE. of Fiume. There are an upper town, built upon two eminences, a lower town, and an episcopal town. The noble Gothic cathedral dates partly from the 11th century. An earthquake in November 1880 made great havoc. The university was founded in 1874. Pop. (1900) 61,002; (1910) 79,038; (1920) 108,338.

Agrarian Laws, the land laws of the ancient Romans, of which the most notable was that of Licinius Stolo, 367 B.C., which provided that every Roman citizen should be entitled to a portion of unallotted state land not exceeding 500 *jugera*, and to feed on the public pasture land 100 large or 500 small cattle. In 133 B.C. Tiberius Sempronius Gracchus revived and extended it. Various agrarian laws were subsequently passed in a contrary sense; see GRACCHUS, LAND LAWS, ROME.

Agri'cola, CNEUS JULIUS (37-93 A.D.), a Roman statesman and soldier born at Forum Julii (now Fréjus, in Provence), served with distinction in Britain, Asia, and Aquitania, and in 78 A.D. was sent by Vespasian as governor to Britain. He was the first to subdue the island, defeated the Caledonians under Galgacus (86 A.D.) at the Grampians, and constructed a chain of forts between the Clyde and Forth, but was recalled by the jealous Domitian in 87 A.D. See ENGLAND; and for the famous life of him by his son-in-law, see TACITUS.

Agricola, JOHANN (originally Schnitter or Schneider; 1492-1566), born at Eisleben, became a Lutheran, and was appointed to a chair at Wittenberg, which he lost as an Antinomian. He was ultimately court preacher at Berlin, wrote many theological works, and made a famous collection of German proverbs.

Agricola, RUDOLPHUS (really Huysman; 1443-1485), foremost scholar of the 'New Learning' in Germany, was born near Groningen, in Friesland; studied at Groningen, Louvain, Paris, and in Italy; and lectured at Heidelberg and Worms. He wrote and argued against scholasticism, and was also a musician and painter.

Agricultural Holdings Acts. See LANDLORD AND TENANT.

Agriculture is still the largest single industry of the British Islands, and despite depression, still bids fair to play a leading part in the life of the nation. The value of agriculture to the community is to be measured not only by the profit it produces, although in this respect it is the most important of all industries, because more than any other it creates wealth where none existed before; but it is also the great mother of men, and provides the most stable and healthy element in the population of the state. Probably no nation can long maintain its greatness unless a considerable proportion of its citizens are occupied upon the land.

In the development of agriculture three stages may be distinguished, which to a certain extent succeed one another in point of time, though all three may be seen in operation together. These may be defined as the Extensive, the Conservative, and the Intensive methods of cultivation. In extensive agriculture, which is practised by all primitive communities, on land which is being

settled for the first time, and on poor lands in the settled countries, the farmer depends wholly upon the fertility which may naturally have accumulated in the soil. He farms wide areas of land, from which with the minimum of toil he removes either crops or the products of grazing animals, continuously robbing the soil and doing nothing to replace the plant-food he removes. Such is the farming of the pastoral nations or of the first settlers upon the virgin soils of North America, the Argentine, &c.; it may be seen again on the rough sheepwalks which still exist in the elevated portions of the British Islands. This extensive form of farming must result in the steady lowering of the accumulated fertility of the soil, though when the land is simply pastured the losses are so small that they are balanced by various natural recuperative actions which go on in the soil.

Under the conservative system of farming the area at the disposal of the farmer is smaller, and he looks to maintain this fertility unimpaired while still drawing from the land a steady revenue of crops and animals fit for food. Such agriculture demands a much greater expenditure of labour on cultivation so as to make the most of the plant-food in the soil; it also demands the return to the soil of the manure made by the stock out of some of the crops that are raised; and, lastly, it involves the growth at regular intervals of leguminous crops which gather nitrogen from the atmosphere and so restore the chief element of fertility. Such a conservative system of farming prevailed in the settled countries of Europe up to the early years of the nineteenth century, and still goes on to-day. In its most finished form it may be seen in a farm worked upon the old four-course rotation, in which turnips and clover consumed by the stock are alternated with wheat and barley. Up to 1830 practically no extraneous source of fertility was available—all the manure had to be made upon the farm and had been drawn from its own soil; but as the sales were confined to wheat and barley grain and to meat, the annual draft on the inherent fertility of the land was small, and as regards nitrogen was balanced by the amount of this element gathered from the air by the growth of the clover-crop. The old English records seem to show that under these conditions land of average quality could be maintained at a pitch of fertility that would yield about twenty bushels of wheat to the acre.

Intensive agriculture has only been possible since 1840, when the discovery of artificial manures in the shape of fertilisers gave the farmer in Great Britain a chance of importing fertility to his land. About that time nitrate of soda and Peruvian guano began to be imported; science taught the necessity of phosphoric acid and opened up the stores which are contained in coprolites and other phosphatic rocks; still later the vast accumulations of potash in Germany became exploited, more extensive deposits of phosphoric acid were discovered, and the amount of this material available was increased by the manufacture of basic slag as a waste product in steelmaking. Not only did science and industry put a greater range of fertilising materials at the disposal of the farmer, but the revolution in the methods of transport effected by steamships and railroads brought to the farmer the products of distant lands, so that British soils became, and still continue to be, enriched with the fertilising materials contained in the maize, linseed, cottonseed, &c. grown in other countries following a more primitive method of agriculture. By the help of this imported plant-food a given area of land may be made to produce greatly increased crops and both more and better stock; as a rule this imported fertility is moderate in amount and only

serves to raise the general level of production of the farm, but some farms exist which are little more than manufactories, where the soil is only a medium converting raw fertilising materials into crops and stock.

The natural development of agriculture is from the extensive through the conservative to the intensive form of cultivation. Indeed, the last word must be with the intensive form, as the world's population overruns the land available. At the present time, however, even in the oldest communities, all three forms may be seen in work simultaneously; the more remote the farm from the cities and the poorer the land, the more will the farmer be driven to a conservative system of farming with the minimum of outlay, while on the poorest land nothing but the extensive system of farming can return a profit. It may be taken as a maxim in agriculture that rich land, in itself possessing considerable natural fertility, will alone repay expenditure on fertilisers and feeding-stuffs. It is usually unprofitable to attempt to convert a poor land into good by high cultivation and liberal manures; only high prices and crops of more than average value will repay intensive farming on indifferent land. Intensive farming naturally calls for higher skill and greater knowledge on the part of the farmer; hence it is to this form of agriculture that the aid of science is indispensable. Indeed, it is fair to say that it has only come into existence since the creation of a science of agriculture. Even at the present time, however, it would not be correct to say that intensive farming is the *best* form of agriculture. Farming is, after all, an industry in which success can only be measured by the profit earned, and if intensive agriculture can claim that the land is put to the best use and made to yield a maximum amount of food for the people, on the other hand extensive farming as practised in the newer countries can equally claim to yield the greatest amount of produce per man employed in tilling the soil.

The relation of science to agriculture has long been a subject of discussion, and is still liable to considerable misapprehension. In the first place, farming is primarily a business, the success of which is to be measured by its personal profit, and no amount of scientific knowledge will make up for lack of skill in marketing or of that mixture of determination and industry which marks the man of business. The farmer may be a most excellent cultivator of the soil or a skilled raiser of stock, and yet fail in buying and selling to the best advantage. Again, the habit of mind which leads to experiments and innovations, in themselves costly, is too often one that insensibly diverts its possessor from the careful pursuit of the routine side of his business. Many of the most valuable improvements in agriculture have been effected by the men who themselves were failures in their business, and this has tended to foster a prejudice in the practical man against any departure from tradition. Moreover, the cultivation of the soil and the management of stock are themselves highly skilled acts which in the older countries are the product of a chain of tradition founded on immemorial experience; science is of comparatively new growth, and has barely assimilated and explained the farmer's instinctive knowledge. Much harm to the cause of science has been done by the rash and short-sighted application of its first discoveries, which could not be otherwise than imperfect approximations to the truth. The growth of a crop or an animal introduces us at once to by far the most complex processes going on in nature; it is indeed the ultimate problem of science, and one that will never be completely solved, because, being the problem of life itself, it is likely

to grow more difficult with each advance of knowledge. As soon as he attempts to apply recognised scientific principles to his industry, the farmer is necessarily brought into contact with the whole range of the sciences. The study of the soil necessitates an acquaintance with geology, with meteorology, with physics, and with chemistry; on the other hand, the living organisms that reside there constitute almost a science in themselves. The plant itself brings one in contact with both chemical and botanical problems. Diseases, again, involve the study of fungi and of a large range of the animal kingdom. The nutrition of the animal has both a chemical and physiological aspect, each of them of a most complex character; and veterinary medicine is no less obscure a field of investigation than human medicine itself. Indeed, it is no exaggeration to say that agricultural science draws contributions from every single science, and generally in their most obscure and difficult stages. It is hardly, then, to be wondered at that the early attempts to apply science to agriculture should have resulted in a good many short views and imperfect generalisations, which, however correct in themselves, could not be applied to the actual march of events, because they left out of account other and larger factors that were at work. The growth of a plant, for example, is conditioned by a number of factors, such as the supply of particular foods, the supply of water, the temperature, the light; and these, in their turn, depend upon other processes at work in the soil or in the atmosphere. While it is easy to fix one's attention upon one of these factors and study the manner in which it affects the plant, this factor may never during the whole of the life of the plant become the particular factor determining the magnitude of the crop. For example, plant-food is essential to crop production—hence it is easy to think that the amount of produce will depend upon the manure the crop receives; but if the water-supply be deficient it will be a matter of indifference to the plant how much manure it has at its disposal—the plant will simply grow as far as the available water permits it.

Despite these difficulties, inherent in the subject, the modern farmer must be equipped with some knowledge of science, which, as far as it affects his subject, may be roughly classified as follows: (1) Geological and Physical—the origin of soils, the physical processes relating to the working of soils, and the movements of water therein. (2) Chemical—the materials requisite for the nutrition of plants and their supply in the soil and in manures; the nature of materials present in the plant and the changes they undergo during the nutrition of animals. (3) Botanical—the structure of the habits of cultivated plants and of weeds; plant diseases; the laws of breeding and development of cultivated plants. (4) Zoological—the life-history of various animals affecting plants and live-stock; the laws of heredity. (5) Veterinary Medicine and Hygiene. (6) Economics—book-keeping and cost of production, capital and labour required; marketing and distribution.

Amid all this complexity we may pretty clearly discern that the improvement of agriculture in the future is likely to follow the three main lines which have marked its history in the past. In the first place comes the improvement in the cultivation of the soil. Not only is the land more effectually worked, but by new implements and more skilful application of power the work is being done with increased speed and cheapness. Small's plough (see PLOUGH) represented a perfecting of the tool of immemorial antiquity whereby the soil was thoroughly turned over. The later improvements have all been in the direction of speed, which has, in its turn, dictated the substitution of horses for oxen, the

setting of the man to ride instead of to walk, the increase in the number of shares, and the use of steam or the internal combustion engines for traction. Just as in the same way the path of progress has been from the sickle to the scythe and cradle, to the reaping-machine, to the self-binder, and to the enormous American machines which cut and thrash great breadths at the same time; speed and the saving of human labour have always been the desiderata. Secondly comes the increase of production by the introduction of better varieties of crops and stock. Enormous as the advance has been from the large seeded grass brought into cultivation by primitive man to the modern wheat-plant, we can still see the possibility of equally great steps of the same kind in the future. Thirdly come the materials used in nutrition. The last word has not been said concerning our artificial fertilisers until we have learnt to get the whole of them back from the land in the crop. Lastly we may place the treatment of diseases both in plants and animals. At the present time disease not only takes a heavy toll from our crops and stock, but prevents production being raised beyond a certain point, for increased susceptibility to disease always attends larger crops and more heavy stocking.

History of Agriculture.—More than with any other art the history of agriculture goes back before the dawn of any record, and its early stages must remain for ever irrecoverable. We find the Romans in possession of an elaborate and effective system, and though to a large extent it perished in the dark ages, the tradition must have continued in many obscure places, and eventually reached us in those improvements which we began to adopt from the Continent in the 14th, 15th, and 16th centuries. The early history of agriculture in the British Islands began with the immemorial system which was common to all Teutonic countries. The land was divided into a series of manors or village communities, each of which was practically self-supporting, possessing its own food and clothing, and having but little trade or intercourse with its neighbours. Putting aside the scheme of tenures that grew up with the feudal system and the position of the lord of the manor, whose land was after all farmed in the same manner as that of his tenants, we may describe medieval agriculture as tillage on the open-field plan by an association of agricultural partners. It is thus described by Mr R. E. Prothero: 'The land of the village farm consisted of meadow, arable land, and pasture. If an open-field farm in Wiltshire be taken as an example, it will be found that in shape it was generally long, narrow, and oblong, hemmed in between the downs and the stream, and often stretching three miles in length. At one end stood the cluster of mud-built, straw-thatched cottages, each with its yard, or small pasture for horses, calves, or field-oxen. Sometimes these yards, or "garstons," were common to all the village tenants for rearing stock or for the oxen which could not "endure his warke to labour all daye, and then to be put to the commons or before the herdsman." In these enclosures, or "happy garstons," as they were called at Aston Boges in Oxfordshire, were held the village merrymakings.'

In the lowest part of the land, if possible along the banks of the stream, lay the permanent meadows, or 'ings,' as they were often called. These meadows were fenced off in strips, and balloted for by the tenants, and held in separate ownership from Candlemas or from Lady-day to midsummer or hay-harvest. As soon as the grass was mown and the hay carried, the meadows once more became open common pasturage, and so remained till they were once more allotted and put up for hay.

Beyond the meadows, and running up into the downs till the soil was too poor and steep for the plough, lay the three great tillage fields. Each year one of these bare, hedgeless fields was sown with wheat or rye, or with a mixture of the two called 'maslin'; another was sown with barley, oats, beans, or pease; the third lay fallow. In this unvarying triennial succession the arable land was tilled and cropped. Each of the three fields was cut up into acre or half-acre strips, divided from each other by narrow, rough, bush-grown balks of unploughed turf. The complete holding of each village was so distributed that each man had a third of his holding in each of the three fields, and the three bundles of strips did not lie contiguously, but were so separated and intermixed that the good and the bad land was evenly distributed. Thus, suppose John Doe to hold eighteen acres of arable land, he would each year have six acres under wheat and rye; six acres under barley, oats, beans, or pease; and six acres fallow; and each of the bundle of strips would be so scattered that the tenant received his due proportion of the best and the worst soil. After the crops were cleared, common rights revived, and the cattle of the village wandered promiscuously over the whole.

Beyond the meadows and the tillage lay the poorest and roughest land, which was left uncleared, affording in its native wildness mast and acorns for the swine; rough pasture for the ordinary stock; timber for building, fencing, and fuel; rushes, reeds, and heather for thatches, ropes, baskets, beds, candles, and a variety of other uses in the farm or the house. In these directions also lay the cow-downs and the sheep-pastures. The herdsman and the shepherd were employed by the villagers to take care of their flock and herd. The rams and bulls were the property of the parish. Sheep were valued more for their wool than their mutton, and cows were chiefly kept for milk, breeding, or draught purposes. The common shepherd drives the sheep of the commoners to the downs, or folds them in the common folds upon the arable land, or, when they require to be fed, pens and feeds them in separate lots, each commoner supplying the food for his flock. On the cow-downs the common herdsman tends the cattle of the community. They begin to feed there in May, and continue to graze the downs till after the hay-harvest and after the arable fields are cleared of their crops. In the height of summer they feed in the small marshes by the river, or along the sides of the lanes, or tethered on the turf-balks, and are only driven to the cow-downs after the evening milking. In the late summer they are turned in upon the aftermath of the hay-meadows, the haulm of the beans and pease, the stubble of the wheat, rye, oats, and barley. No winter keep was known to the open-field farmer. He turned a deaf ear, as has been said, to the suggestions of book-agriculturists. Consequently it was only at the wane of the summer that his cattle were more than skin and bone. From Michaelmas onwards they steadily declined in condition, and only survived the winter in a state of semi-starvation. The roast-beef of Old England, for the enormous majority of the population, consisted of the worn-out oxen or the aged cows that were slaughtered in the autumn, when at their fattest, and salted for winter consumption. 'For Easter at Martynmas hang up a beef' is the advice of Tusser.

Such was the system in which the greater part of the cultivated land of the country was tilled in the 17th and 18th centuries. The defects of it are sufficiently obvious. Unless the whole body of farmers agreed together, no individual could move hand or foot. It would be financial ruin

for any member of the community to grow turnips or clover for the benefit of his neighbours. No winter crops could be grown so long as the arable fields were subjected to common rights of pasture. The land was wasted in innumerable footpaths and balks. The strips were too narrow to admit of cross-harrowing or cross-ploughing. Farmers spent the whole day in visiting the different parcels of which their holdings were composed, and their expenses in reaping and carting were immensely increased by the remoteness of the different strips. Drainage was impossible, for if one man drained his land or scoured his courses, his neighbour blocked his outfalls. Consequently the arable land was rarely cleaned; it was choked with docks and thistles, overrun with nettles and rushes, pitted with wet places, pimped with ant-hills and mole-heaps. Litigation was perpetual when it was so easy for men to plough up the common balks or headlands, remove their neighbours' landmarks or poach their land by a turn of the plough, or filch their crops when reaping. As long ago as Piers Plowman there had been complaints against reapers reaping their neighbours' ground, and in Robert de Brunne's *Handlyng Synne* there is a reference to the false 'husbands' that 'ere aweye falsly mennys landys.' The manure of the live-stock of the village was wasted by the immense area over which the animals travelled. The promiscuous herding of the sheep and cattle generated every sort of infectious disorder. The scab was rarely absent from the common fold, or the rot from the ill-drained field. No individual owner could improve his own live-stock when all the half-starved, diseased cattle and sheep of the village were crowded together on the same commons. Moreover, from the productive point of view, the wastes and commons were a standing reproach to the rural economy of the country, and were capable of being turned to more profitable account in the hands of enterprising individuals than under the common control of a large body of ignorant, prejudiced, and suspicious copartners.

The general description which has been given applies to almost every part of the country. Scotland formed no exception to the rule. Scottish farmers, who are now reckoned among the most skilful, were in 1689 inferior to those of England, and their methods of raising crops had remained unchanged since the battle of Bannockburn. Alexander Garden of Troup describes the system which was followed in 1686. The land was divided into infield and outfield. The infield was kept 'constantly under corne and bear, the husbandman dunging it every thrie years, and, for his pains, if he reap the fourth corne he is satisfied.' The outfield was allowed to grow green with weeds and thistles, and after four or five years of this repose, was twice ploughed and sown with corn. Three crops were taken in succession, and then, when the soil was too exhausted to repay seed and labour, it reverted to its thistles and weeds.

Under such a system no real improvement was possible; and although we find that Sir Richard Weston, who had been ambassador in the Palatinate in the time of Charles I., grew turnips and artificial grasses on his farm at Sutton in Surrey, their inclusion in the agriculture of the country could only take place when the open fields were broken up and the manors were enclosed so as to give each tenant a piece of land under his permanent control.

The change from the open-field system began as the country emerged from medieval times under the Tudor sovereigns. We find enclosures taking place freely, and the process was renewed with great vigour as soon as the Civil War was over.

Early in the 18th century we find from the writings of William Ellis that a great part of Hertfordshire was already being farmed on very much the same system as prevails to-day. The process, however, was far from complete, and it was not until the growth of the manufacturing population increased the demand for food, especially aided by the great rise in prices of all produce attending the Napoleonic wars, that the land of Great Britain was finally thrown into its present form of holding. During the reign of George III. no less than 6,300,000 acres were enclosed, and from the writings of Arthur Young we see that enclosure was still regarded as the necessary first step towards improving the general agriculture of the country. The gain to the nation at large was undoubted. Intensive agriculture became possible, and the production of food for the rapidly growing population was enormously increased, the landlord obtained rents which were undreamt of before, and the farmer became a rich and prosperous element of the community. There is, however, another side to the question. The small common field farmer was in many cases crushed out of existence, and either sank down into the position of a labourer or was driven into the towns. The population residing upon the land became greatly reduced, and the rural labourer in the early years of the 19th century sank into a position of poverty and absolute dependence upon his master which existed in no other walk of life. From this physical and moral depression of one of the most important elements in the community we have as yet hardly recovered; indeed, the effort which is now being made to recreate a number of small holdings only represents an attempt to repair the measure of injustice and mischief which was incidentally effected by the enclosures.

From the time of the enclosures, however, agricultural improvement began. Many of the soldiers who fought in the Low Countries during the religious wars from the time of Elizabeth to Charles II. brought back with them to Britain the methods, the crops, and the stock which they had seen in that highly cultivated country. During the 17th century we have a number of books, like Blith's *English Improver Improved* (1652) and *Samuel Hartlib his Legacie* (1651), giving an account of these improved practices and indicating the path of progress. It is with the 18th century, however, that we really begin to see modern systems of farming emerge, and the man who above all others we may call their founder is Jethro Tull, who, born in 1674 and educated in Oxford, then made a tour of the Continent, noting everywhere the methods of agriculture. From 1700 to 1740 he farmed in Berkshire, experimenting in all kinds of ways on the cultivation of the soil, as a result of which he invented his system of drilling and horse-hoeing. In his *Horse Hoeing Husbandry*, published in 1733, he laid down the principles of cultivation in masterly fashion; and all subsequent works, both scientific and practical, have done little more than confirm and explain the methods which Tull then expounded. Tull's demonstration of the value of turnips and of sowing in drills that permit of cultivation between the rows was, however, long in gaining acceptance amongst the working farmers; it was only the example of a number of great landlords that really drove home Tull's lessons. Of these men Lord Townshend merits the first place. He retired from politics to his estate of Rainham in Norfolk in 1730, and there he devoted himself to the improvement of farming. He marled his light land, he grew turnips whereby to make manure for the corn, and if not the inventor, he was the man who promulgated and made the agricultural community realise the value of that fundamental rotation which we are accustomed to call the

'Norfolk Four-course System.' Other men, like Lord Ducie and Lord Halifax, worked on the same lines; and in Scotland, under Lord Cathcart and Mr Hope of Rankellor, the Scottish Society of Improvers in the Knowledge of Agriculture was founded. In 1723 this society leased an extensive morass on the south side of Edinburgh, and there demonstrated the value of enclosure, draining, liming, and fallowing; showing also the Scottish farmer what could be done with clover and sown grasses. Closely following these improvements in cultivation of crops came the improvement of stock, and here John Bakewell of Dishley, Leicester, is the father of the modern pure-bred herd. Before his time different parts of the country did possess various types of cattle and sheep, but breeding was promiscuous, the sheep were valued for their wool alone, and the standard in cattle may be gauged by the Lincolnshire ox that was exhibited all over the country—'nineteen hands high, and four yards long from his face to his rump.' Bakewell began his work about the middle of the 18th century, and in a very short time made himself famous, so that visitors came from all parts of the world to see his farm. He began his work with the local breed of sheep, probably crossed them with the white-faced, hornless Ryland because of its peculiarly fine fleece, and by careful selection of rams, and then by interbreeding amongst those animals only which conformed to the ideal he had in his mind, with astonishing rapidity he produced a uniform flock of a value hitherto undreamt of. His object was not only to secure uniformity but animals which had the most flesh on the best joints and which would rapidly grow into maturity. In fact, all the desiderata of the modern breeder—finesse of bone, early maturity, a compact and symmetrical carcass, a fine and even fleece—were attained in Bakewell's new Leicesters. His work was at once appreciated; in 1755 Bakewell let rams at sixteen shillings each for the season; in 1789 a society paid him 1600 guineas for the hire of his rams for the season. Not only did Bakewell's work create the modern Leicesters, but in their turn the Leicesters have communicated their good qualities to most of our modern breeds of sheep, and again his principles of breeding have been taken up by other men and applied to their own local races. As a cattle-breeder Bakewell was less permanently successful, because the Longhorns upon which he worked did not seem to possess the same innate capacity for improvement. It was Charles Colling (1751-1836), working upon Bakewell's lines with the local cattle of Tees-side, who created the modern Durhams or Shorthorns.

Though the actual improvements in agriculture in the 18th century were due either to tenants like Bakewell, Colling, Ellman, or to men unconnected with agriculture, like Small, who improved the plough, and Meikle, who invented the first thrashing-machine, it was the example of the great landlords that more than anything else spread a better system of farming. Of these men the most famous is Coke of Holkham in Norfolk, who created a fertile estate out of a waste by methods like those of Townshend. In 1778 he began those famous gatherings of farmers known as the 'Holkham Sheep Shearings,' at which men from all parts of the country, indeed all parts of the world, met in the morning to see the farming and the sheep, and then proceeded to a great lunch and an afternoon of toasts and speeches. Similar gatherings were held at Woburn by the then Duke of Bedford, one of the most ardent of improvers, and by the enthusiasm thus generated the practice of the best farmers began to be spread all over the country. In Scotland Lord Kames played a similar leading part, and out of the work of the Scottish Improvers and his example

came the foundation of the Highland Society in 1784. But amongst the prophets of modern farming the first place must be given to Arthur Young, who, born in 1741, spent a long and active life travelling both over the British Islands and through France, visiting everything in the nature of an improvement, and writing with singular force and lucidity about what he had seen. As a farmer Young failed more than once; no man can live by trying all the improvements at once, but he really knew his farming from top to bottom, and as an agricultural writer is never likely to be matched. The influence he had obtained by his *Annals of Agriculture* (1784-1809) and his *Tours* (1768-89) was only increased when he was made secretary of the newly founded Board of Agriculture in 1793, and from this time to his death in 1820 he continued to press untiringly the adoption of enclosures, the system of drilling and horse-hoeing, and the introduction of the improved breeds of stock. The epoch of high prices which had helped so much towards the revolution of British farming came to an abrupt close with the end of the Napoleonic wars in 1815. Prices fell with a crash; rents had to be reduced, though not rapidly enough to save many farmers from ruin; above all things, the small yeoman was crushed out of existence at this time because he had borrowed money on the strength of the continuance of the old prosperity. The crash, however disastrous it seemed at the time, was probably beneficial to the industry. Men went more carefully to work, and as the industrial population of the country was increasing by leaps and bounds, the demand for agricultural produce grew year by year, prices began to rise again, and a new epoch of prosperity rapidly set in. From 1830 onwards the great landlords of the country were still set on improving their estates and raising the status of farming. With the foundation of the Royal Agricultural Society of England in 1838, a society which really grew out of the old Board of Agriculture that had ceased to exist in 1822, we see the enlightened interest which many of the landowners of the country were taking in farming. At this period, too, began the introduction of artificial fertilisers and foreign feeding-stuffs. Nitrate of soda and guano began to come to the country about 1840, in 1842 Lawes took out his patent for superphosphate, and in a very few years all the farmers in the country were growing their turnips with the aid of these new manures. It was the introduction of this extraneous source of fertility which above all other things increased the productive power of England's land. Lawes estimated the average crop of wheat in his district at about twenty bushels at the time he began his farming; it had certainly become thirty bushels in the next twenty years, and this in the main had been rendered possible by the new sources of fertility. From 1840 to 1872 agriculture was continually prosperous; not only was the art of crop-raising brought to its highest pitch of refinement on the great farms of the Lothians, but all our present breeds of cattle and sheep took shape, and were improved and reduced to uniformity along the lines laid down by Bakewell for his Leicesters. Britain began to send her pedigree stock all over the world, and the Shorthorn, the Hereford, and the Devon founded great herds in America, Australia, New Zealand, and later in the Argentine. In the late 'seventies a change began; American competition was beginning to make itself felt until prices both of wheat and beef were set by the importations and not by the home productions; finally a succession of wet seasons and bad harvests, culminating in the disastrous summer of 1879, worked havoc amongst the arable farmers. During the 'eighties things grew steadily worse; in too many cases landlords mistook a

permanent change in the agricultural conditions for a temporary depression, rents were not reduced until the tenants were ruined, and on the strong land in the east of England many farms for a time could find no tenants at all, but sank down in a derelict state, until they had become covered with a miserable vegetation of grass and weeds. It was the arable farmers who were chiefly hit by this depression, especially the men on the strong lands in the east of England; graziers in the midlands and the west suffered less because meat and particularly milk maintained their values. The year 1894 saw about the lowest level of prices, and since that time agriculture has been entering upon a slow but steady period of prosperity. The great readjustment of rents has taken place, cheaper methods of cultivation have been learnt, and if something of the old finish has departed from British farming, the methods are more business-like, and better advantage is being taken of the resources which science has put at the disposal of the farmer. Above all things, prices have been steadily rising, and with the enormously increased output of gold seem likely to be maintained for some little time.

Agricultural Education.—The preparation of the modern farmer for his future career involves, or should involve as a matter of course, some systematic education in the principles of agriculture, but how far that course should extend must still to a large extent depend upon the size of the holding and the style of farming which is within the reach of the young man in question. The farmer who is likely to have some command of capital, so as to be able to become a tenant of a farm of two to five hundred acres, may profitably go through a regular college course extending over three years; but the smaller farmer will probably derive a greater benefit by attending short courses of instruction during several successive winters, while in the summer he works on his father's farm. The education of this class of farmer is also provided for in some districts by farm schools, which take boys at the age of fourteen or fifteen and give them a certain amount of practical and scientific instruction while continuing their general education. At the present time Great Britain is fairly well provided with colleges giving a higher form of instruction, but an adequate supply of winter courses of instruction and farming schools for the smaller farmers has hardly as yet been organised.

Systematic agricultural education in Great Britain may be said to have begun in 1890, when the so-called 'whisky money' was handed over to the county councils to be spent on technical education. Out of these funds many counties, acting either singly or in groups, established agricultural colleges or subsidised agricultural departments at the nearest university, and in this policy they were assisted by the Board of Agriculture, which in 1888 was given a grant from the Treasury for the encouragement of agricultural colleges and dairy schools. In the year 1910-11 the Board of Agriculture made grants (annual) to twenty institutions in England and Wales, amounting in all to £18,840. In Scotland similar work is under the charge of the new Board of Agriculture, which subsidises the three agricultural colleges at Edinburgh, Glasgow, and Aberdeen. In Ireland the work is organised and supported by the Department of Agriculture and Technical Instruction. More recently the Development Commission has made considerable grants to the agricultural colleges for capital purposes, and also an annual grant to enable them to provide technical advice for the farmers within the area which they serve. A considerable sum has also been set aside for the extension of secondary education in agriculture. The following list shows in brief the

provisions now made for agricultural instruction in the United Kingdom.

In Scotland, the East of Scotland Agricultural College, the West of Scotland Agricultural College, and the North of Scotland Agricultural College are attached to the respective universities of Edinburgh, Glasgow, and Aberdeen. Each provides a full course of agricultural instruction extending over three years and leading to the university degree of B.Sc.; each also provides a shorter diploma course of instruction and winter courses of short duration for men already engaged in farming. These colleges also provide courses of lectures and other forms of itinerant instruction in the various counties in the three areas into which Scotland has been divided for educational purposes, a resident lecturer being posted in each county, who not only gives lectures in the winter, but conducts field experiments and demonstrations during the summer months.

The University of Edinburgh was the first to institute a degree in agriculture in 1886. It is still the only one of the Scottish universities which accords full professorial rank to a teacher of agriculture. This professorship was, indeed, founded and endowed in 1790, a few years earlier than the creation of the Sibthorpe professorship at Oxford, which, further, was so poorly endowed that it has only become effective and acquired a resident holder during the last few years. At Oxford this re-endowment of the Sibthorpe professorship has been accompanied by the formation of a school of rural economy, and agriculture has now become one of the final subjects by which a student may proceed to his degree. At the University of Cambridge a school of agriculture has been at work for some time, and professorships both of agriculture and agricultural botany have been established within the university, together with readerships in agriculture and agricultural zoology. The university awards a diploma which is open to others than members of the university, while certain agricultural subjects may also be offered towards the ordinary degree.

The Armstrong College at Newcastle-on-Tyne is associated with the University of Durham, and provides instruction leading up to the degree of B.Sc., and also to a college diploma. It possesses a farm and experiment station at Cockle Park, Alnwick, and conducts experiments and gives lectures in the three northern counties. The University of Leeds provides a course leading up to the B.Sc. degree. The college farm and experiment station is situated at Garforth. The University of London also provides an examination for the degree of B.Sc., and this may be taken by external students as well as by the students of the South-east College at Wye, which is one of the constituent colleges of the university. The college at Wye also provides other courses of instruction leading up to the college diploma and certificate. The Cheshire Agricultural College at Holmes Chapel has recently been affiliated to the University of Manchester, where provision is now being made for granting the degree of B.Sc. in agriculture. In England there are also colleges which are not directly connected with any university conferring the degree. Of these the oldest is the Royal Agricultural College at Cirencester, which was founded in 1845, and has recently been reorganised and brought into connection with the local county councils and with the University of Bristol. The Midland Agricultural and Dairy College at Kingston, Notts, provides a general agricultural course leading to a diploma, as well as a special course of dairy instruction. The Harper Adams Agricultural College at Newport, Salop, provides a course of instruction leading up to a diploma; as also does the Agricultural Department of the

University College, Reading, where, further, the British Dairy Farmers' Institution provides systematic instruction in dairy-work. In addition to these, long courses of agricultural education are provided at the Harris Institution, Preston, and the Agricultural College, Uckfield, Sussex. The Essex County Laboratory at Chelmsford provides short courses of instruction; while there are farm schools, at Penrith belonging to Cumberland and Westmorland, at Basing belonging to the Hampshire County Council, and at Ridgmont belonging to the Bedfordshire County Council.

In Wales the University Colleges at Bangor and Aberystwith provide full courses of instruction leading to the degree of B.Sc. of the University of Wales. In Ireland agricultural education is in the hands of the Department of Agricultural and Technical Instruction, who provide a full course of training at the Royal College of Science, Dublin, in connection with the Albert Agricultural College at Glasnevin.

It is a matter of considerable debate whether in the education of a farmer a course at an agricultural college should precede or follow residence upon a farm in order to acquire the indispensable practical acquaintance with the working conditions of the industry. Probably for the sons of farmers who already know a good deal about life upon a farm the best plan is to take the college course immediately on leaving school; but in the case of boys coming out of a town the preliminary residence of a season upon a farm is desirable before they go to a college, in order to give a student some general acquaintance with farming matters. Such a student should also join a farm as a pupil after the completion of his college course. See Report of the Departmental Committee appointed by the Board of Agriculture to inquire into the subject of Agricultural Education in England and Wales (1908).

Agricultural Research.—Although agricultural research has never received in this country the attention that has been paid to it in many Continental states and in America, the United Kingdom possesses the oldest of all agricultural stations, and one that has done the most to lay the foundations of agricultural science. The Rothamsted Experimental Station was founded by the late Sir John Lawes in 1843, in which year he obtained the assistance of the late Sir J. H. Gilbert, in order to put upon a systematic basis certain experiments which he had already begun to carry out upon his estate at Rothamsted, near St Albans, Herts. For many years Lawes carried on the experiments entirely at his own expense and under his own control, and in 1889 he created the Lawes Agricultural Trust, endowing it with stock to the value of £100,000. The laboratory and the lease of the land upon which the experimental plots are situated he entrusted to the management of a committee composed of four members nominated by the Royal Society, two by the Royal Agricultural Society, and one each by the Chemical and Linnean Societies and the owner of Rothamsted.

At Rothamsted field experiments have been carried out on a large scale to ascertain the manurial requirements of the various farm crops, and their yield under various conditions. The distinguishing feature has been the continuity of plan; each particular plot has always carried from year to year the same crop, and has received similar treatment and manuring. The accidental errors due to variations of soil and season, which are inherent in all field experiments, are thus eliminated, and the effect of the treatment stands out clearly. From such results over a series of years the influence of different types of season can be ascertained; and in the course of time the secondary

effects of the treatment on the composition and behaviour of the soil also become apparent; exhaustion of the soil in particular directions manifests itself by degrees. The effect of the manures used on the gross yield of the crops may be regarded as settled by these experiments; indeed the results are nowadays incorporated into the current tradition of the practical farmer; but the effects produced upon the soil and upon the quality of the crop are still matters which urgently require investigation, for which the Rothamsted plots provide unique material.

While field experiments with farm crops have always been the main subject for investigation at Rothamsted, many other cognate matters have been dealt with. For a long time feeding experiments were conducted with cattle, sheep, and pigs, in the course of which analyses were made of the whole bodies of these animals in various stages of fatness. These experiments still form the basis of our knowledge of the composition of the animal body. Other experiments have dealt with the nature and amount of food required by the fattening animal, and with the relation of food to work and the source of fat in the body; all of these have assisted in laying the foundations of the theory of animal nutrition. More directly practical inquiries have dealt with the value of malt as food, with the utilisation of sewage and the feeding value of sewage-grown grass, and with the making and feeding value of ensilage.

The investigations on the soil have been continuous, and have related chiefly to the manner in which it gains or loses fertility, including a detailed examination of the substances removed in the water draining through arable land. Mr Warrington, when working in the Rothamsted Laboratory, determined the conditions under which the nitrates, upon which nearly all plants depend for their nitrogen-supply, are formed or destroyed in the soil by bacteria. Much information has also been accumulated on the action of the bacteria, either associated with leguminous plants or living free in the soil, that fix the atmospheric nitrogen and so gain fertility for the farm.

In 1899 the papers in which the results of the Rothamsted work were embodied were collected, forming three 4to and 8vo volumes, sets of which were distributed by Sir John Lawes to the chief libraries, colleges of agriculture, and experiment stations in the world. A more general summary of the work done is contained in the *Book of the Rothamsted Experiments*, published by J. Murray (1905; price 10s. 6d. net). The *Guide* to the Rothamsted experiments shows the current conditions of cropping and yield.

In 1876 the Royal Agricultural Society began experiments on a farm at Woburn which was provided by the Duke of Bedford. Since that time experimental plots dealing with wheat and barley on similar lines to the plots at Rothamsted have been maintained on its light, sandy soil; and a number of other experiments both on crops and animals are also being carried out under the supervision of the society's chemist, Dr J. A. Voelcker. The Highland and Agricultural Society have also conducted a long series of agricultural experiments both on a permanent station which they for some time held at Pumpherton, and on a more extensive scale by the co-operation of farmers in different parts of the country. The Bath and West of England Society has also conducted a number of similar experiments by co-operation of farmers in the south and west of England. Of recent years the establishment of a number of agricultural colleges has added to the agricultural research done in this country. Mention may particularly be made of the extensive investigations conducted

by the Agricultural Department at Cambridge on the experimental breeding of cereals, which have already resulted in the production of several new varieties of wheat and barley which promise to be superior to any that are at present at the disposal of the farmer. The Irish Department of Agriculture does not possess any special agricultural station, but has conducted a large number of experiments by co-operation with farmers. Among these may be particularly noticed an extensive series of tests on varieties of barley, and trials of early potato-growing which have already established this industry on suitable soils in the south of Ireland, together with trials of tobacco and flax. In 1911 the much-needed extension of agricultural research in the United Kingdom was inaugurated by the action of the Development Commission, which has set aside a sum of about £40,000 annually for the foundation of research institutes dealing with the main branches of the subject and the encouragement of agricultural investigations in the universities and colleges.

Agriculture in the United Kingdom.—The characteristic feature of agriculture in Great Britain is that it is for the most part carried on by tenant-farmers holding comparatively large farms for which they pay a fixed rent and which they work with their own capital. At one time it was customary to hold these farms on a sufficiently long lease to give the tenant a prospect of recovering his expenditure on improvements of a more or less permanent character, but since the great depression yearly tenancies have been much more general. By custom the landlord is called upon to execute repairs to the buildings and make other outlays of a capital nature, while the various Agricultural Holdings Acts give the tenant security of compensation for other improvements he may have executed during his tenancy. By the custom of the country which has become legalised by the Agricultural Holdings Act, the incoming tenant or the landlord pays to the outgoing tenant a valuation to represent the standing crops and the work which has been done upon the land for which the outgoing tenant has received no return, together with the unexhausted value of fertilisers and feeding-stuffs consumed upon the farm. Compensation must also be paid for such improvements as laying upon land the grass, drainage, and additional buildings, provided the improvements have been made with the consent of the landlord. This system, which gives the tenant the responsibility for the management of the farm, has undoubtedly done much to bring British agriculture into its high position, because it has held out sufficient hopes of return to keep men of capital in the business of farming, and has thus led to intensive farming and a high standard of the utilisation of the land. Cumbersome as the system may appear to be, it has in a general way worked extremely well, and has only led to difficulties where the tenant has taken up special crops and departed widely from the normal routine of farming, so that it becomes difficult to apply the usual customs of compensation at the close of the tenancy.

Owing to its greater rainfall the western side of Great Britain contains a greater proportion of grass-land than the eastern. At the present time arable land as the leading feature of the farming is mainly confined to the south of England and to the belt which stretches up the east coast as far as Aberdeen. In the south-west of England grazing predominates, the production of milk, butter, and cheese, and the raising of cattle, being the dominant features of the industry. In Cornwall there is also fertile arable land close to the sea which is highly valued for the production of early vegetable crops. In Somerset, again, there is a small area of

exceptionally good arable land on which barley of very high quality is produced. Orcharding and the making of cider form also a notable feature in the agriculture of Devon and Somerset. Dorsetshire is largely a dairy county, but the chalk uplands of Wiltshire, Hampshire, and west Sussex are largely under the plough. Raising of sheep forms a prime feature in this farming, the sheep being folded on the arable land for the greater part of their life. Kent, and with it part of east Sussex, is characterised by highly specialised systems of farming, in which the production of fruit and of hops plays a very prominent part. The heavy lands of Essex have of late years been largely given up to milk-raising. In Norfolk and Suffolk the grass-land is of little moment, and corn-growing, with bullock-fattening, forms the mainstay of the farming. In the fen country the growing of corn and potatoes and the raising of heavy horses are characteristic features of the farming. Intensive potato-growing is also to be seen on the warp soils of Lincolnshire, while on the wolds arable farming and sheep are prominent. The midlands of England are largely occupied by heavy clay soils derived from the Lias and other clay bodies of the Jurassic formations. This land is mostly in grass and forms the great milk-producing area of England, while on the better land a certain amount of bullock-fattening is carried on. In the west midlands, Worcestershire, Herefordshire, and Gloucestershire, fruit-growing becomes the leading industry, and in this area hops again become prominent on the good lands in the river valleys. This country joins on to a well-managed and often very fertile district, of which Shropshire is the centre, where mixed farming is comparatively prevalent, and the raising of sheep and cattle a valuable item in the industry. In Cheshire dairy-farming and the raising of potatoes are general, as also along the western border of Lancashire, specially in the Fylde district north of the Ribble. In these two counties the farms are generally comparatively small, and are maintained at a high pitch of cultivation. Yorkshire, again, presents some fine farming country with very distinct types of soil in the Vales, the Wolds, and the alluvial area of Holderness respectively. Mixed farming of a most varied type prevails; perhaps the raising of light horses constitutes its most distinctive feature. Along the sea-border of Durham and Northumberland stretches a belt of comparatively light land highly farmed on a four-course system, the staple products being barley, sheep, and cattle fattened in the stalls. This arable country crosses the border into the notable farming district which extends by Dunbar through the Lothians up to Edinburgh. This district constitutes perhaps the most highly farmed land of the United Kingdom, fat bullocks, sheep, and barley being the chief products, while the potatoes grown on the red soils in the neighbourhood of Dunbar possess a special repute. North of Edinburgh the highly farmed arable country continues through Forfarshire, the Carse of Gowrie, Strathmore, and up the east coast as far as Aberdeen, winter fattening of bullocks being the mainstay of the industry, while barley for the distilleries and oats form the other chief sources of revenue. In the neighbourhood of Blairgowrie an important fruit industry has sprung up of recent years, and a considerable portion of the land is occupied by raspberries and other soft fruits. The south-west of Scotland is mainly given up to the dairy industry, but on the coast of Ayrshire there is an area where the growing of early potatoes forms the most important industry. Cumberland and Westmorland, again, are in the main dairying and stock-raising districts. The more elevated parts of Great Britain are largely given up to the raising of stock which are afterwards sold into the lowlands to be

fattened. Wales possesses several breeds of mountain sheep of considerable repute, and also raises the well-known black muntjaks which are sold into the east of England to be fattened. Dairy produce forms also a feature of the Welsh farming. The uplands of the south of Scotland are chiefly given up to the production of sheep and store cattle, like the Galloways and the well-known blue-gray cross, which travel southward for fattening. The Highlands of Scotland, again, are generally farmed for sheep, but also export considerable numbers of their well-known breed of cattle. In Ireland the agriculture is naturally undergoing considerable changes with the revolutions that are taking place in the system of landholding. For a long time the chief agricultural exports of Ireland have been cattle of a Shorthorn type, which are in great demand all over the midlands and east of England for fattening purposes, and butter, especially from the south and west. Light horses are also raised to a very large extent. The area under arable cultivation is not large, though the average yield per acre is high. In the north of Ireland a considerable, though shrinking, area is devoted to flax.

Agricultural Societies.—Potent factors in agricultural progress have been the agricultural societies which have existed for the last hundred years or more in various parts of the country. By their annual shows they have done much towards the improvement of live-stock, and have greatly forwarded the introduction of new implements; several of them have also been the effective agencies in the spread of education, before the creation of the numerous agricultural colleges which now exist. The societies were also pioneers in the provision of facilities for obtaining analysis of manures, &c., tests of seeds, and other expert information for their members. For a long time they were, again, almost the only agencies carrying on systematic experiments and demonstrations on the use of fertilisers and trials of new varieties of plants. The oldest of the societies is the Highland and Agricultural Society, which dates from 1784, and was incorporated by Royal Charter in 1834. The society had in 1911 about 6500 members, a capital of £111,179, and an income in the same year of £16,043, of which £6229 consisted of receipts from the annual show. The society holds an annual show in different parts of Scotland, publishes an annual journal, gives expert advice by means of its officers to its members, and assists local agricultural associations throughout Scotland. Jointly with the Royal Agricultural Society of England, it conducts examinations in agriculture and in dairying, on which the national diploma in these subjects is granted. The Royal Agricultural Society of England was founded in 1838, and had in 1911 over 10,000 members. Its invested funds amounted to £56,375, and its annual income was £9791, exclusive of all receipts and expenditure connected with the show. It holds an annual show in various parts of England, publishes a journal, provides expert advice on chemical, botanical, zoological, and veterinary matters for its members, and shares in the conduct of the national diploma examinations with the Highland and Agricultural Society. The Bath and West of England Society was established in 1777, and has 1200 members. Its funds amounted in 1911 to about £20,100, and its annual income was £11,827, of which £10,114 was in respect of the show. This society also publishes a journal, provides expert advice for its members, and carries on experimental work, especially in connection with dairying and cidermaking. The Royal Dublin Society was founded in 1731, and has 3400 members, with a subscription income of nearly £5000. It holds four shows during the year at Ballsbridge, Dublin, of which the horse show, held in August, has a world-

wide reputation. The Central Chamber of Agriculture meets eight times in the year in London, and represents about 20,000 members belonging to the affiliated chambers of agriculture in all parts of the country. Its objects are to watch over all measures affecting agriculture in and out of parliament. The National Farmers' Union was founded in 1908, and consists of representatives of farmers' unions throughout the country, these unions having been founded for the purpose of watching over matters affecting farmers. The distinguishing feature of this society is that no one is eligible as a member unless he is carrying on the business of farmer in actual practice. The Smithfield Club in London was founded in 1798, its object being the holding of an annual fat stock show. Three societies exist for the purpose of promoting co-operation and organising agricultural co-operative societies throughout the kingdom. These are the Irish Agricultural Organisation Society, which was the pioneer in this direction; the Agricultural Organisation Society; and the Scottish Organisation Society. The Farmers' Club (London) was founded in 1842, and has now about 1000 members. It has premises in London, and holds eight meetings during the year for the discussion of agricultural subjects. The British Dairy-Farmers' Association was founded in 1875, and has now about 1000 members. Its objects are the improvement of dairy stock and dairy produce, to which end it publishes an annual journal, holds an annual conference and discussion, and an annual show in London. This society also founded the British Dairy Institute, which is now carried on at Reading in connection with the University College. In addition to these general agricultural societies, almost all the varieties of horses, cattle, sheep, and pigs bred in the United Kingdom are represented by societies, each of which issues an annual stud-book and register of pure-bred stock, and either holds a special show or gives premiums and special prizes at the shows throughout the country. These societies have done much towards improving the breeds and the establishment of an export trade in pedigree stock, which is one of the most notable features in British farming.

Board of Agriculture.—The Board of Agriculture and Fisheries was established in 1849, and deals with the agriculture of Great Britain. It is represented in parliament by its president, and possesses a permanent secretary and staff. To this department were transferred many duties previously administered by the Board of Trade, Privy Council, and the Lands Commissioners. The functions of the department may be considered under five divisions. The animal division is chiefly concerned in the administration of the Diseases of Animals Acts, and possesses, in addition to its central staff, a number of inspectors throughout the kingdom, whose duties consist in the control of such diseases as swine-fever, sheep-scab, &c. To this division is also attached a research department. The land division is charged with the administration of the Small Holdings and Allotments Acts in England and Wales, and deals with applications of landowners to improve and charge their societies under the Improvement of Land and other Acts; with the appointment of arbitrators, &c., under the Agricultural Holdings Acts; and with the sale of glebe land and university and college estates. The statistical division collects and compiles the annual agricultural returns as to the acreage and production of crops, number of live-stock, and prices of agricultural commodities. An annual report is published, which may be obtained from any bookseller. The intelligence division collects and disseminates general information relating to agriculture. It issues a monthly journal and

leaflets from time to time giving advice on special topics. It is charged with the inspection of the agricultural colleges to which the Board gives grants, and all the business arising out of the Sale of Food and Drugs Act, the Fertilisers Act, &c. The Royal Botanical Gardens at Kew and the Ordnance Survey of the United Kingdom are also administered by the Board of Agriculture. The annual expenditure of the Board for the year 1908-9 was £148,124. By the Small Landholders (Scotland) Act of 1911 the duties of the Board of Agriculture in Scotland were transferred to the Scottish Board of Agriculture, which receives an annual grant of £200,000 for the general purposes of the Board and for the acquisition of land for small holdings. The Department of Agriculture and Technical Instruction for Ireland was established in 1899, and exercises for Ireland similar functions to the Board of Agriculture in England. It possesses, further, entire control of the agricultural education in Ireland, and has large powers in carrying out experiments and assisting the improvement of agriculture throughout Ireland. This department is assisted by a council appointed in part by the various councils of Ireland and the Agricultural Board, whose members are nominated by the provincial committees of the agricultural councils. The annual expenditure for the year 1908-9 was £95,561.

Agricultural Statistics.—The agricultural statistics for the United Kingdom are published annually for England, Scotland, and Wales by the Board of Agriculture in four parts, issued by Messrs Wyman and Co., and for Ireland by the Department of Agriculture and Technical Instruction in a single report issued by the same firm. The total area of land and water, with the cultivated area, rough grazings, and woodlands, is given below for each country (in thousands of acres).

	Total Area, Land and Water.	Cultivated Area	Rough Grazings	Wood- lands.
England....	32,392	24,541	2,416	1,715 *
Wales.....	4,750	2,782	1,324	184 *
Scotland....	19,070	4,860	9,108	868 *
Ireland. ...	20,351	17,135	2,470	302

* 1905.

The total area under cultivation has been showing a small but continuous decline for the last fifty years in all the countries except Ireland, this being due to the extension of urban areas, the withdrawals from cultivation having been more or less balanced by the taking in of fresh land from the uncultivated fringe. But the most striking change which has been seen in this period has been the loss of the arable land, with a corresponding increase in the permanent grass. England and Ireland show this change most markedly; in Scotland the area of arable land has been better maintained.

The division of the land and its distribution into various-sized holdings are shown for each country in the following table:

NUMBER OF HOLDINGS.				
	England.	Wales.	Scotland.	Ireland
Over 1 and not over 5 acres .	80,195	10,210	18,058	61,780
Over 5 and not over 50 acres..	165,661	31,945	34,490	864,549
Over 50 and not over 300 acres	109,768	18,004	23,189	81,104 *
Over 300 acres..	14,642	387	2,677	9,513 †
Total ..	370,266	60,546	78,359	601,765

* Over 50 and not over 200 acres. † Over 200 acres.

In the following table are set out for the year 1909 the acreage under the principal crops in the

four countries; while the next table shows the change that has been taking place in this allocation of the land by a comparison of the areas in 1888, 1898, and 1908 respectively.

	England.	Wales.	Scotland	Ireland.*
	Acres	Acres	Acres	Acres
Wheat. . . .	1,734,286	39,583	40,679	36,677

* Not separated into 'breeding ewes' and 'other sheep,' but divided according to age—'under one year old' and 'one year and over'

The average yield of some of the principal crops for the ten-year period 1899-1908 in the four countries is set out in the following table:

	England.	Wales	Scotland	Ireland
	Bushels.	Bushels.	Bushels	Bushels
Wheat.	31 89	26 39	38 86	34 41
Barley.	32 91	31 09	35 32	40 09
Oats.	41 75	34 48	36 60	46 03
Peas.	27 39	21 53	26 07	20 88
Beans.	29 77	26 56	34 78	41 53
	Tons	Tons	Tons	Tons
Potatoes. . . .	5 58	4 98	6 09	4 37
Turnips and swedes	12 57	14 88	15 55	16 17
Mangolds. . . .	19 70	17 40	17 87	18 01
Clover and other rota-	Cwt	Cwt	Cwt.	Cwt.
tion grasses. . .	29 64	24 92	32 80	42 77
Permanent grass cut				
for hay.	24 12	19 46	29 72	47 02

In comparing the yield in the United Kingdom with those of other countries the data available are not always sufficient, but are more complete as regards wheat than any other crop. The following table gives the mean yield in bushels per acre up to 1908 for the five previous years, together with the acreage:

	WHEAT.		BARLEY.	
	Mean Area	Mean Yield per Acre	Mean Area	Mean Yield per Acre.
	Acres.	Bushels	Acres	Bushels
United Kingdom	1,664,561	31 58	1,988,983	33 31

United States. . .	46,782,150	18 48	5,601,260	25 64

* 1907 only.

The prices obtained for some of the leading products of the farm are set out in the following table, a comparison being made of the averages obtained in the years 1888, 1898, and 1908:

	1888.	1898.	1908.
	s. d.	s. d.	s. d.
Wheat . . . per quarter	31 10	34 0	32 0
Barley . . . "	27 10	27 2	25 10
Oats "	16 9	18 5	17 10
Potatoes . . . per ton	—	—	71 1
Meadow hay . . "	—	—	61 6
Beef per cwt.	47 5	41 5	50 7
Mutton. . . . "	59 4	52 1	60 1
Pork "	—	—	52 6
Wool per lb.	0 0½	0 8	0 8½

As the imports of foreign produce have such a dominating effect upon the prices obtained by the British farmer, in the following table are set out the quantities imported in the years 1888, 1898, and 1908 of the chief articles entering into competition with British produce:

	1888.	1898.	1908.
Wheat . . . cwt	57,261,388	65,227,980	61,181,205
Flour. "	16,910,442	21,017,109	12,969,855
Barley "	21,805,580	24,457,004	18,137,200
Oats "	18,770,686	15,577,900	14,269,250
Beef. "	1,068,602	8,591,110	5,997,964
Mutton. "	988,010	3,482,815	4,450,877

* Oilcake.

The articles on the several countries contain sections on their agriculture; see especially those on the United States, Canada, Australia, New Zealand, and Argentina. There are articles on Anthrax, Rinderpest, Murrain, Pleuro, and the other annual diseases; on Wheat, Barley, Oats, Grasses, Pasture, Bean, Beet, Carrot, Cabbage, Clover, Hops, Lucerne, Maize, Mangold-wurzel, Potato, Turnip, Vetch, and the diseases that attack them; on Allotments and Peasant-proprietorship, and many other agricultural articles, such as:

Butter.	Farm	Manure.	Sheep.
Cattle.	Fodder.	Nutrication	Soils.
Cheese.	Guano.	Parasitic Animals.	Threshing.
Cream.	Hay.	Pig	Physiology
Dairy.	Horse.	Plough.	(Vegetable).
Drainage	Irrigation.	Poultry.	Veterinary
Ensilage	Land Laws.	Reaping.	Medicine.
Fallow.	Landlord.	Rotation.	Waste Land.

See Fream's *Elements of Agriculture*, enlarged by Ainsworth-Davies (5th ed. 1905); Stephens's *Book of the Farm*, revised by Macdonald (5th ed. 1908-9); *Standard Cyclopædia of Modern Agriculture*, edited by Sir R. Patrick Wright (12 vols. 1908-10); *Encyclopædia of Agriculture*, by Green and Young (3 vols. 1907-8); *Cyclopædia of American Agriculture* (1908); *English Farming Past and Present*, by R. E. Prothero (1912); M'Connell's *Agricultural Note Book*; Wrightson's *Principles of Agricultural Practice*; and *A History of Agriculture and Prices in England*, by J. A. Thorold Rogers (8 vols. 1866-1912). On live-stock: R. Wallace's *Farm Live Stock of Great Britain* (4th ed. 1907); *Youatt's Complete Grazier*, edited by Fream (1908); J. Wilson's *Evolution of British Cattle*, Sinclair's history of *Shorthorn Cattle* and of *Hereford Cattle*, Wrightson's *Sheep* (6th ed.), and Sanders Spencer's *Pigs* (4th ed.). On scientific branches: R. Warington's *Chemistry of the Farm* (20th ed.); A. Percival's *Agricultural Botany* (3d ed.); A. D. Hall's *Feeding of Crops and Stock*, *The Soil and Fertilisers and Manures*; Kellner's *Scientific Feeding of Cattle* (trans Goodwin); and Theobald's *Agricultural Zoology*. And amongst periodicals these may be consulted: *Journal of the Royal Agricultural Society of England* (annual); *Journal of the Highland and Agricultural Society of Scotland* (annual); *Journal of the Board of Agriculture* (monthly); *Journal of the Department of Agriculture for Ireland* (monthly); *Journal of Agricultural Science* (annual).

Agrigentum (Gr. *Akragas*), a Greek town on the south coast of Sicily, founded by a colony from Gela (itself a Doric colony 50 miles to the eastward), is said in the 5th century B.C. to have had 200,000 inhabitants, and its territory extended right across Sicily. It was demolished by the Carthaginians in 405 B.C., and in the Punic wars it was compelled to submit to the Romans. In 1036 A.D. it was taken from the Saracens by Roger Guiscard. The modern Girgenti (q.v.) still shows numerous and splendid ruins, of which the best preserved is the Temple of Concord.

Agrimony (*Agrimonia*), a genus of Rosaceæ (q.v.), sub-order Potentillæ. The Common Agrimony (*A. eupatoria*) is a native of Britain and other parts of Europe, growing in borders of fields, on waysides, &c.

Agrippa, CORNELIUS (1486-1535), a cabalistic philosopher, born at Cologne of noble family,

early entered the service of the Emperor Maximilian, was Colet's guest at London in 1510, lectured at Pavia, and was made doctor both of law and medicine, provoked the enmity of the monks and the Inquisition at Cologne, and practised medicine at Fribourg in Switzerland and Lyons. Appointed historiographer to Charles V. at Antwerp, he published on the vanity of the sciences and on the occult philosophy, and was accounted a magician; strange tales being told of his black poodle, of his magic mirror, and of his over-curious pupil, who was rent in pieces by demons. See his *Life* by H. Moiley (1856).

Agrippa, M. VIPSANIUS (63-12 B.C.), a Roman general who commanded Octavian's fleet at Actium (31 B.C.), and did good service in Gaul, Spain, Syria, and Pannonia. See also **HEROD**.

Agrippina, daughter of Agrippa and Julia (daughter of Augustus), was a faithful wife to Germanicus, but, banished by Tiberius to the island of Pandataria, died by voluntary starvation in 33 A.D.—Her daughter, **AGRIPPINA**, one of the most detestable of women, was born at Cologne, and married Ahenobarbus, by whom she had a son, afterwards the Emperor Nero. Her third husband was the Emperor Claudius, whose enemies she systematically poisoned. Ultimately she was put to death by Nero in 59 A.D.

Agtelek, a village on the Hungarian-Czechoslovak frontier, near a remarkable labyrinth of stalactitic caverns, some nearly 100 feet in height.

Agnado, ALEXANDER MARIA (1784-1842), born at Seville of Jewish family, took service with the French, was aide-de-camp to Soult, and settling at Paris, became one of the wealthiest of bankers.

Agua Calientes, capital of a Mexican state, 270 miles NW. of the city of Mexico; pop. 45,000.

Ague. See **MALARIA**.

Aguesseau, HENRI FRANÇOIS D' (1668-1751), a very learned and public-spirited lawyer, born at Limoges, was thrice chancellor of France, defended the Gallican liberties, opposed Law's financial schemes, and wrote many volumes on law, economics, philosophy, and theology.

Aguilar, a town of Spain, 26 miles SSE. of Cordova, trading in corn and wine; pop. 13,000.

Aguilar, GRACE (1816-47), born of Jewish parentage at Hackney, lived long in Devonshire, and wrote *The Spirit of Judaism* and a number of graceful religious fictions.

Aguilas, a port in the Spanish province of Murcia, exports ores, esparto, and figs; pop. 6000.

Agulhas, CAPE, the most southern point of Africa (q.v.), lies about 100 miles ESE. of the Cape of Good Hope. The Agulhas Bank extends along the whole southern coast of Africa.

Ahab, king of Israel, allied himself in 854 B.C. with Assyria (q.v.) against Syria. He married Jezebel, daughter of Ethbaal, king of Sidon, and by her was the father of Athaliah (q.v.). He sanctioned the worship of Baal. Mesha, king of Moab, was tributary to him.

Abasuerus is the name or title by which several kings of Media and Persia are mentioned in Scripture (see **ESTHER**); as also the traditional name of the Wandering Jew (q.v.).

Abaz, king of Judah, hard pressed by Edomites and Philistines, by Israel and Damascus, called to his aid Tiglath Pileser of Assyria (q.v.).

Ahlquist, AUGUST ENGELBERT (1826-89), professor of Finnish at Helsingfors, wrote grammatical and lexicographical works.

Ahmedabad (better *Ahmadabad*), chief town of a district in Guzerat, second amongst the cities of the province of Bombay, is 50 miles NE. of the head of the Gulf of Cambay. It was built in the year 1412 by Ahmed Shah, and finally came under the power of the British in 1818. It was formerly one of the largest and most magnificent cities in the East, and in the 18th century had a pop. of 900,000. Its architectural relics are gorgeous, even in the midst of decay, and illustrate the combination of Saracenic with Hindu forms mainly of the Jain type. The Jama Masjid, or Great Mosque, rises from the centre of the city, and is adorned by two superbly decorated minarets. There is likewise an ivory mosque, so called because, although built of white marble, it is lined with ivory and inlaid with a profusion of gems. There are some twelve other mosques and six famous tombs. The modern Jain temple is of singular beauty. The prosperity of the place was almost wholly destroyed by the rapacity of the Mahrattas, but it has largely recovered, and is still famous for its manufacture of rich fabrics of silk and cotton, brocades, and articles of gold, silver, steel, and enamel. The pottery is very superior; and paper of various sorts is largely manufactured, chiefly from jute. Pop. (1901) 185,889; (1921) 274,202.—The *district*, mainly a great alluvial plain, has an area of 3800 sq. m., and a pop. of 1,000,000, of whom about a tenth are Mohammedans.

Ahmednagar (*Ahmadnagar*), a town of the province of Bombay, 122 miles E. of Bombay, is the third city of the Deccan. In 1797 it fell into the hands of the Mahrattas, and in 1817 of the British. It became a municipality in 1855. Strong carpets, cotton and silk cloths, and copper and brass pots are manufactured. Population 42,940, mostly Hindus. There are several smaller places of the same name in India.

Ahmedpur, a meanly built town of India, in the native state of Bahawalpur, 25 miles SW. from Bahawalpur; pop. 18,414.

Ahmed Shah, the first monarch of Afghanistan, born about 1724, was the son of Seman Khan, chief of the Abdali tribe. He served in the bodyguard of Nadir Shah (q.v.), and on his assassination retired to Afghanistan, where he induced the native tribes to revolt and to choose him sovereign. His wealth and military talents made him popular, and he gradually so far extended his conquests that, on his death in 1773, he left to his son, Timur, an empire which reached from Khorasan to Sirhind, and from the Oxus to the Indian Sea.

Ahn, JOHANN FRANZ (1796-1865), was born at Aix-la-Chapelle, and was a teacher in his native city and at Neuss. His French Grammar for Germans (1834) went through more than 200 editions, and was succeeded by similar works on English, Italian, and Dutch. Ahn's method—an extension of Seidenstücker's (died 1817)—is that of making the example precede the rule, so that the pupil learns a foreign language much as, when a child, he learned his own.

Ah'riman (Zend, *anro mainyus*, 'dark spirit'), the evil principle, opposed to Ormuzd, in the dualism of later Zoroastrianism. See **ZOROASTER**.

Ahwaz, a town of Persia, in Arabistan province, on the river Karun (q.v.), is the centre of a grain district; pop. 4000. Near it are ruins of the capital of Artabanus, last of the Parthian kings.

Aid, FIRST. See **BANDAGE**, **AMBULANCE**.

Aidan, ST, the founder of the Northumbrian Church, was sent from Iona in 635, in answer to King Oswald's summons, to become the Bishop of Northumbria. He established himself in the island of Lindisfarne, and, thence making missionary

journeys to the mainland, achieved a great work, in spite of the ravages of Penda, the heathen ruler of Mercia. He died at Bamborough in 651.

Aidé, HAMILTON (1830-1906), English poet and novelist, was born at Paris, the son of an Armenian and of a daughter of Admiral Sir George Collier. He served seven years in the British army, and then settling down in the New Forest, devoted himself to literature. Among his poems are *Eleonore* (1856) and *Songs without Music* (1882); among his novels, *Euta* (1859), *The Marstons* (1868), and *Passages in the Life of a Lady* (1887).

Aide-de-camp, an officer attached to the personal staff of a general officer. He carries all orders on the field of battle, and, when thus acting as the mouthpiece of the general, is to be implicitly obeyed; an aide-de-camp's mistake led to the famous but undesigned light cavalry charge in the Crimean war. In garrison and quarters the aide-de-camp superintends the general's household, and acts as his secretary. Before an officer can be appointed an aide-de-camp, he must have served a certain number of years with his regiment. Intelligence, linguistic qualifications, and good horsemanship are generally taken into account; and in practice officers above the rank of captain are seldom selected as aides. A major-general has one, a lieutenant-general two, and a general three aides-de-camp; in the field, four aides are allotted to the officer commanding in chief, and two to a brigadier; each receives an addition to the pay of his rank. As nominal head of the army, the sovereign may have an indefinite number of aides-de-camp, and the office is much sought after, both as an honour and as conferring the army rank of full colonel. In 1919 the king had (besides 'personal' and princely aides) about sixty aides-de-camp, mainly chosen for distinguished war services, and some nine naval and marine aides-de-camp.—In the United States army a lieutenant-general is allowed two aides and a military secretary, with the rank and pay of lieutenant-colonel; three and two aides respectively are allotted to major-generals and brigadiers, selected in the former case from captains and lieutenants.

Aidin (*Guzel-Hissar*), a town of western Asia Minor, on the Meander, was built out of the ruins of the ancient Tralles. It lies 60 miles S.E. of Smyrna by railway; it gave name to a vilayet, but the seat of government was Smyrna. Pop. 37,000—many Greeks, Armenians, and Jews. Its trade in morocco leather, cotton, and fruit is important.

Aids. These were originally payments to which every tenant in chivalry was liable. (1) To ransom the person of the lord when taken prisoner; (2) To make his eldest son a knight; and (3) To provide a suitable portion to his eldest daughter on her marriage. Tenants in socage were liable only to the latter two, and the mesne lords were prohibited by Magna Charta from exacting more than these three. The last feudal aid exacted was in 1346 for knighting the Black Prince. These incidents of tenure were abolished in 1672. Scutage (q.v.) and Tallage (q.v.), and the Benevolence (q.v.), were arbitrary taxes of this kind which led to disputes between English kings and their subjects down to King Edward III.'s reign, although the right to levy such taxes without the consent of the realm was formally renounced in the confirmation of charters by Edward I. The name of aid was, however, also applied, down to the time of William III., to parliamentary taxes for extraordinary purposes, including the land-tax. See FEUDALISM, TAXATION.

Aigrette is the French name of the bird known in England as Egret (q.v.), the lesser white heron. Hence the term came to be used for its feathery

crest, for feathers in a lady's head-dress, and more loosely for any head-dress like a plume, a bouquet of flowers, or an ornament of precious stones. Botanically it is equal to pappus, down of a seed, like thistle down.

Aigues-Mortes (*Aquæ Mortuæ*), a small town in France (pop. about 4000), in the department of Gard, with fine complete medieval ramparts. It is situated in an extensive salt-marsh, and is about 3 miles from the Mediterranean, with which it is connected by a canal. In the middle ages, when the sea came much nearer the town, it was a very important Mediterranean harbour. St Louis sailed thence in 1248 and 1270 for the Crusades.

Aiguille (Fr., 'needle'), an instrument used by military engineers to pierce a rock for the reception of gunpowder, when any blasting or blowing-up is to be effected. The word is also used of the needle-like peaks or summits of mountains, especially in the Alps.

Aikin, JOHN, son of a Unitarian tutor, was born at Kibworth, Leicestershire, 15th January 1747, and after studying at Edinburgh and London, took his M.D. degree at Leyden University (1780). He practised in Chester, Warrington, Yarmouth, and London; but in 1798 retired to Stoke-Newington, where he died 7th December 1822. A friend of Priestley, Darwin, John Howard, and Southey, he was a voluminous author; his works including *Lives of Howard, Selden, and Usher*; the *General Biography* (10 vols. 1799-1815); and the well-known *Evenings at Home* (6 vols. 1792-95), written in conjunction with his sister, Mrs Barbauld (q.v.).—His daughter, LUCY AIKIN, was born at Warrington, 6th November 1781, and died at Hampstead, 29th January 1864. She was author of *Epistles on Women* (1810); *Lorimer, a Tale* (1814); *Memoir of John Aikin, M.D.* (1823); *Memoirs of the Courts of Elizabeth, James I., and Charles I.* (6 vols 1818-33); and *Life of Addison* (1843). See her *Memoirs, Miscellanies, and Letters* (1864).

Aikman, WILLIAM, Scottish portrait-painter, was born at Cairnie, Aberdeenshire, in 1682, and died in London in June 1731. Intended by his father for the law, he followed the bent of his own inclination, and studied art instead in Edinburgh and Rome. Aikman settled in Edinburgh, and practised portrait-painting with success till 1723, when he was persuaded by the Duke of Argyll to remove to London. He executed many important commissions, including portraits of Gay, Thomson, John Duke of Argyll, Lady Grizel Baillie, and Allan Ramsay. His style was modelled on that of Kneller.

Ailanto (*Ailantus glandulosa*, the 'tree of heaven'), a lofty and beautiful tree, of the natural order Simarubaceæ, a sub-order of Rutaceæ, a native of South-eastern Asia, was brought from China in 1751, and is now frequently planted to shade public walks in France and Italy. It has also been introduced into Germany, Britain, and the United States, but is apt to be injured by frost when young. The leaves are large and pinnate, with an odd leaflet resembling those of the ash. The tree grows very well on chalky soils, and is easily propagated. The wood is fine grained, satiny, and suited for cabinet-making, and the leaves afford nutriment to a species of silkworm (*Bombyx Cynthia*). It is sometimes known as Vernis du Japon, apparently by confusion with certain species of Rhus.

Ailly, PIERRE D' (or Petrus de Alliaco), theologian and Nominalist philosopher, was born in 1350. Chancellor of the university of Paris, and Bishop of Compiègne, he was made cardinal in 1411, and a papal legate in Germany. He took a chief part in

the Council of Constance, where he headed the reform party, but agreed to the sentence on Huss and Jerome of Prague. He died at Avignon in 1419.

Ailsa Craig, a rocky islet of Ayrshire, 10 miles W. by N. of Girvan. Rising abruptly out of the sea to a height of 1114 feet, it forms a most striking object. It is about 2 miles in circumference, and is accessible only at one point, where the accumulation of débris has formed a rough beach. The rock may be described generally as a mass of trap, assuming in some places a distinct columnar form, with dimensions far exceeding those of the basaltic pillars of Staffa. On the NW., perpendicular cliffs rise to a height of from 200 to 300 feet; on the other sides, the Craig descends to the sea with a steep slope, covered with grass and wild-flowers, with numerous scattered fragments of rock. Till the erection of a lighthouse (1833-86), the only inhabitants were goats, rabbits, and wild-fowl; solan geese, in particular, breeding in the cliffs in countless numbers. About 200 feet from the summit are some springs, and on the ledge of a crag on the eastern front, are the remains of an ancient stronghold. In 1831, the Earl of Cassilis, the proprietor of Ailsa Craig, was raised to the dignity of Marquis of Ailsa.

Aimard, GUSTAVE, the French Fenimore Cooper, was born in Paris, 13th September 1818, and shipping as a cabin-boy to America, spent those ten years of adventure in Arkansas and Mexico which furnished the themes of most of his novels. He travelled also in Spain, Turkey, and the Caucasus; in Paris served as an officer of the *Gauche Mobile* (1848); organised the *Francs-tireurs de la Presse* against the Germans (1870-71); and after some years' confinement in an asylum, died 20th June 1883. Of his very numerous novels many have been translated into English. Gustave Aimard was a pen-name, his real name being Ollivier Gloux.

Ain, a French river rising in the mountains of Jura, and flowing 118 miles south-westward, through the departments of Jura and Ain, till it falls into the Rhone, 18 miles above Lyons.

Ain, an eastern department of France, separated from Savoy by the Rhone. The eastern part is mountainous, with summits 5000 to 6500 feet high. The area is 2240 square miles, and the population about 316,000. Bourg is the capital.

Ainger, ALFRED, son of a London architect, was born in 1837, graduated from Trinity Hall, Cambridge, and after holding a cure near Lichfield, in 1866 became a reader at the Temple Church, in 1887 a canon of Bristol, and in 1894 Master of the Temple. Author of the articles on Lamb and Hood in this work; of selections, with a memoir, from Hood; and of a book on Crabbe ('Men of Letters' series, 1903), he is best known in literature as biographer (1882, 1888) and editor (6 vols. 1883-88) of Lamb. He died 8th February 1904.

Ainmiller, or AINMÜLLER, MAX EMANUEL (1807-70), was born in Munich, was trained in the royal porcelain manufactory there, but, discovering new methods in glass-painting, became director of a great establishment for that art.

Ainos, a race who were probably the first inhabitants of Japan, but who now are reduced to about 15,000, confined chiefly to the islands of Yezo and Sakhalin. They are short in stature, but strongly built, and the bodies of many are covered with short, bristly hair. They speak a language distinct from Japanese, and appear to be rapidly dying out. Their features are rather European than Mongolian. They exist principally by hunting and fishing, and are polygamous. See JAPAN; and books by Chamberlain (1887), Batchelor, Savage Landor (1893), and Torii (1919).

Ainslie, HEW (1792-1878), poet, was a native of Ayrshire, who in 1809 became clerk in the Register House at Edinburgh, and in 1822 emigrated to America, where, after a spell in Robert Owen's community at New Harmony (q.v.), he managed breweries. He wrote three or four very fair lyrics and more than a hundred very indifferent ones, and a *Pilgrimage to the Land of Burns* (1822; new ed. 1892).

Ainsty, a territorial division or jurisdiction in some parts of England, as in Cambridge, Dorset, Devon, but especially York (q.v.); see *Notes and Queries*, July 1904.

Ainsworth, ROBERT (1660-1743), lexicographer, was born at Woodvale, near Manchester; and, educated at Bolton, taught a school there, until, about 1698, he removed to London. In 1714-36 he produced his (now obsolete) Latin Dictionary—one of several educational works.

Ainsworth, WILLIAM FRANCIS, an English physician, geologist, and traveller, was born at Exeter in 1807. He studied medicine at Edinburgh, and, after receiving (1827) his medical diploma, he travelled in France, and prosecuted geological investigations in the Auvergne and Pyrenean mountains. Returning to Edinburgh in 1828, he conducted the publication of the *Journal of Natural and Geographical Science*, and delivered lectures on geology. In 1832-33 he did good service against the cholera; in 1835 he was attached as physician and geologist to the Euphrates expedition under Colonel Chesney, and returned home in 1837 through Kurdistan, the Taurus, and Asia Minor. In 1838-41 he visited the East with Rassam and Russell, their chief objects being to explore the course of the Halys, and to visit the Nestorian Christians in Kurdistan. Amongst his works are *Researches in Assyria, &c.* (1838); *Travels in Asia Minor, &c.* (1842); *The Claims of the Christian Aborigines of the Turkish Empire* (1843); and *Travels in the Track of the 10,000 Greeks* (1844). He died 27th November 1896.

Ainsworth, WILLIAM HARRISON, was born in Manchester, February 4, 1805, and educated at the grammar-school. A solicitor's son, in his seventeenth year he was articled to a solicitor; and on his father's death in 1824, came up to London to complete his legal studies. Two years later, however, he married a publisher's daughter, and himself turned publisher for eighteen months. He had contributed some articles to magazines prior to 1822, so that his first-born was not *Sir John Chiver-ton* (1826), an anonymous novel, bepraised by Scott, but partly, it seems now, the work of a Mr Aston. Anyhow, his earliest hit was *Rookwood* (1834), with its vivid description of Dick Turpin's ride to York. By 1881, a period of close upon half a century, he had published no fewer than thirty-nine novels. Several of these appeared originally in *Bentley's Miscellany*, *Ainsworth's Magazine* (1842-54), and the *New Monthly*, of which he was successively editor; and seven of them were illustrated by Cruikshank—viz. *Rookwood*, *Jack Sheppard* (1839), *Tower of London* (1840), *Guy Fawkes* (1841), *Miser's Daughter* (1842), *Windsor Castle* (1843), and *St James's* (1844). To these may be added his *Crichton* (1837), *Old St Paul's* (1841), and *Lancashire Witches* (1848), as possessing some intrinsic claim to literary merit. He died at Reigate, January 3, 1882. See *Life* by S. M. Ellis (1910).

Ain-Tab, a town of Turkey, on the Sadjur, an affluent of the Euphrates, 64 miles NNE. of Aleppo. The chief trade is in inferior tissues. Ain-Tab is supposed by some to be the ancient *Antiochia ad Taurum*. Pop. 70,000, composed of Turks, Greeks, and Armenians.

Air, or ASBEN, an oasis-kingdom in North (French) Sudan. Agades (q.v.) is the capital. The

country is principally inhabited by three tribes, all Tuaregs, with some admixture of negro blood. The valleys are naturally rich in tropical vegetation, but they are poorly cultivated. Although the valleys of Air are in the region of the tropics, the climate is comparatively temperate.

Air is the mixture of gases constituting our atmosphere. Formerly all aciform fluids were called 'airs' (oxygen being called *dephlogisticated air*); but in this sense the word 'gas' is now used. For the chemical composition of air, its chief properties, and the phenomena they give rise to, see **ATMOSPHERE**; also **AIR-PUMP**, **BAROMETER**, **BALLOONS**, &c., **GASES**, **STORMS**, **WIND**, &c.; and for the law as to air, the last paragraph of the article **LIGHT**.

Air, in Music, see **ARIA**.

Air-bath. See **COMPRESSED-AIR BATH**.

Air-beds, or **AIR-MATRESSES**, differ only in shape and size from air-cushions, half-beds, pillows, and the familiar travelling-cushions. They were first made at a moderate price after the introduction of Mackintosh cloth, an air-tight fabric consisting of two pieces of cloth united by an interposed layer of india-rubber spread on in solution. They are still made in essentially the same way, a thin sheet of vulcanised rubber being placed between the two layers of cloth, and the whole made into one fabric, so to speak, by pressure. When they are inflated, either by the mouth or by a pair of bellows, a screw stop-cock prevents the escape of air. An air-bed consists of a sack in the form of a mattress, usually divided into a number of compartments, each air-tight; a projection at one end forms a bolster. Each compartment has a valve, through which the air is blown in. Air-beds and pillows are valuable in cases of sickness, but are not so lasting or so comfortable as Water-beds (q.v.) and water-pillows, which are formed of thicker material, consisting entirely of vulcanised india-rubber. The latter are, however, double the price of the former. When the air-bed or mattress is not made with several air-tight compartments, the walls of the single compartment are tied to each other at various points, so that the whole may preserve its shape when inflated. Air-beds are not merely valuable in cases of sickness, but are useful for camping out, and are available for military purposes. Their worst fault is their liability to be spoilt by a rent or puncture; and if not taken good care of, they crack and become troublesome or useless. Air-beds were known as early as the beginning of the 18th century, but being made of leather, were expensive.

Air-bladder, or **SWIMMING-BLADDER**, a thin-walled sac, containing gas, which lies underneath the backbone of most bony fishes. It arises as a

Air-bladder of Carp :

Consisting of two parts, B and C, joined by a narrow neck; A D, a canal communicating with oesophagus, E.

pouch from the gut, usually from the region of the gullet, and its stalk often remains open, as the so-called pneumatic duct. In the primitive *Polypterus* of the Nile and West African rivers, the air-bladder lies ventrally. In the mud-fishes or *Dipnoi* it functions as a lung, and points the way to the lungs of land vertebrates. As to its function in ordinary bony fishes there is still some uncertainty. It has glandular tissue on certain parts of its lining, and can secrete gas, thus discharging an aerostatic

function, and enabling the fish to adjust itself to varying pressure at different depths. The store of oxygen may possibly help in some cases in respiration. As the anterior end of the air-bladder is often connected with the ear, the organ may act as a resonator, or possibly in making the fish more sensitive to changes of pressure and the like. In a few cases the muscular contraction of the bladder produces sounds by setting internal membranes in vibration. This interesting organ has also some practical importance to man since it furnishes the finest kind of isinglass. See also the article **FISHES**.—The **AIR-SACS** connected with the lungs of birds are treated in an article at page 113 below.

Air-cells, or preferably **AIR-SPACES**, in plants, are cavities containing air in the stems or leaves, which aid greatly in effecting the interchange of gases necessary for the life of the plant. They consist for the most part either of the intercellular spaces, or of cavities formed by rupture, as in grass and umbelliferous stems. In terrestrial plants they communicate with the exterior by means of the *Stomata* (q.v.). An interchange is thus established between the living cells of the plant and the outer air, and this is helped by movements due to wind, by changes of temperature, and the like. They are especially large and numerous in many Aquatic Plants (q.v.) which are partly or entirely floating—mainly owing their buoyancy to this cause.

Aird, THOMAS, minor poet, was born at Bowden, Roxburghshire, in 1802, and in 1816 passed from the parish school to the university of Edinburgh. There he made Carlyle's acquaintance; whilst, as tutor in the family of a Selkirkshire farmer, he often met Hogg, the Ettrick Shepherd. He was destined for the church, but preferred to devote himself to letters, and in 1826 published *Martzouffle, a Tragedy, with other Poems*; in 1827, *Religious Characteristics*, a series of prose essays which Professor Wilson eulogised in *Blackwood's Magazine*. From 1835 till 1863 Aird edited the *Dumfries Herald*, a new Conservative journal. *The Devil's Dream*, his best-known poem, has a Landoresque, if not Dantesque grandeur; but Aird's poetry has never become popular. Whether the themes are colossal, as in *The Devil's Dream*, or pathetic, as in *My Mother's Grave*, there is the same clear, vigorous, picturesque word-painting. In 1845 appeared his *Old Bachelor in the Scottish Village*, a volume of tales and sketches; in 1848, a collected edition of his poems; and in 1852 he edited the select poems of David Moir ('Delta'). Aird died at Dumfries, 25th April 1876. See the Life by J. Wallace, prefixed to the fifth edition of his poems (1878).

Airdrie, a flourishing town in NE. Lanarkshire, 2 miles E. by N. of Coatbridge, and 11 E. of Glasgow. Standing on the high-road between Edinburgh and Glasgow, near the Monkland Canal and the London and North Eastern Railway, it owes its prosperity and rapid growth to the abundance of coal and ironstone in the vicinity. Mining, iron manufacture, and engineering are the leading industries. The weaving of cotton goods for Glasgow manufacturers is carried on to a considerable extent, as also is paper-making. In 1832-1918 it united with Falkirk, &c., in sending a member to parliament, and it became a municipal burgh in 1849. Pop. (1831) 6594; (1861) 12,918; (1891) 15,133; (1901) 22,288; (1921) 25,092.

Aire (ancient *Vicus Julii*), a French town in the department of Landes, on the Adour, 112 miles S. of Bordeaux. It is a bishop's seat, and has an ancient cathedral. Aire, famous in Roman times, was the capital of the Visigoths under Alaric, but is now much decayed. Pop. 4000.

Air-engine, a form of heat-engine in which air is the working substance. Captain Ericsson called his latest air-engine a *caloric-engine* (see CALORIC).

It is a well-known condition, applicable to all heat-engines, that (presupposing the working parts of the machine to be the best possible) the heat converted into work bears the same proportion to the total heat given to the working substance as the range of temperature bears to the *absolute* temperature of the source of heat. Thus, supposing an engine to receive steam (and the law is the same for steam, air, or *any other substance whatever*) at the temperature of 275° F., and discharge it at that of 120° F., the fraction of heat which it can

convert into work will be $\frac{275 - 120}{275 + 461}$ or about 21 per cent. of the total heat supplied. This proportion would be, of course, greatly reduced in practice, owing to imperfections in the machinery; but these being equally likely to occur in all prime movers, we need not consider them here. The *lowest* limit of temperature available being practically constant, fixed either by the temperature of the atmosphere, or that obtainable in a condenser, it follows that greater economy can only be looked for in the direction of increase of initial temperature. In ordinary steam-engines, in which the pressure and temperature increase simultaneously, the latter is limited by the former, which in its turn is kept, by considerations of safety, comparatively low. When, however, *superheated* steam (steam whose temperature is above the condensing-point) or heated air is used, the temperature is limited only by the power of the metals composing the machine to resist the internal pressure of the steam or air, the destructive action of heat, or the chemical action of the fluid at that temperature. With heated air an explosion, at a given temperature, is less likely because of the lower pressure, and would be comparatively harmless. It also enables the separate boiler to be dispensed with. With steam, the danger arises from the great increase of volume when water evaporates, unless the steam is subjected to very great pressure.

Air-engines, in their principal working parts, are very similar to ordinary steam-engines. The heated air is introduced into a cylinder, in which works a closely fitting piston, which is thus compelled to move up and down, and transfers its motion to a revolving shaft by means of a piston and connecting-rod in the usual manner. The motion of the piston results in all cases from the expansion of the heated air; the air is heated by means of a furnace, is introduced below the piston, raises it, and then is allowed to escape into the atmosphere. Air-engines are almost invariably single-acting; they are sometimes worked simply by heated air, and sometimes with the air which, having passed through the furnace, is mixed with all the gaseous products of combustion. The latter method has the immense advantage that it utilises the heat which would otherwise be rejected into the chimney, and so prevents considerable waste of fuel.

The more heat carried away by the discharged air—the higher its temperature, in other words—the smaller evidently is, *ceteris paribus*, the range of temperature of the machine, and the less, therefore (as already explained), will be its efficiency. The distinctive principle of Stirling's air-engine, as of the later air-engines, consists in utilising a great part of this wasted heat, and thus economising fuel. This is effected by means of a 'regenerator,' or, more properly, 'economiser,' consisting of a chamber filled with metallic sieves of wire-gauze, through which the hot air is made to pass *outwards* from the cylinder, after having

performed its work on the working-piston of the engine. As much of the heat of the escaping air is taken up by the regenerator, and its temperature thus reduced, the range of temperature of the machine is correspondingly increased. The fresh air entering the cylinder for the next stroke is compelled to pass *inwards* through the regenerator, and abstracts from it the heat left in it. In this way it does not require to receive so much heat in the furnace as would otherwise be the case, and thus economises fuel.

The figure shows one of Stirling's air-engines. E is the plunger which works in the receiver CAB.

This receiver is double, the inner lining being pierced with small holes to admit of communication between the annular space and the interior. The regenerator is placed in the space AC. By the motion of the plunger the air is alternately admitted to the upper and under portions of the receiver, passing through the regenerator. The upper portion is always in communication with G, the cylinder, in which the piston H works. At D is placed the 'refrigerator,' a coil of copper tube through which cold water passes. This refrigerator abstracts the heat wasted through imperfect action of the regenerator.

This method of preventing waste of heat was first discovered by the Rev. Dr Stirling, who obtained a patent for it in 1816. In working with air at the ordinary pressure of the atmosphere, however, the engine was found to require to be of large dimensions as compared with a steam-engine of the same power; and in order to obviate this objection, compressed air was used, the idea originating with Mr James Stirling, C.E. Several other difficulties were successfully surmounted by the Messrs Stirling, and eventually two improved engines were constructed, one of which was tested to fully 40 horse-power. This latter engine did all the work of the Dundee Foundry Company regularly for upwards of three years, during which period they employed no other motor. At the end of this period it was laid aside, principally owing to the repeated failure of one of the heating vessels.

Captain Ericsson, in his attempt to introduce his caloric-engine in the ship which bore his name, experienced precisely the same difficulties and disappointments, and tied nearly the same remedies. The chief trouble is failure of the material of the heater, caused by the rapid changes of temperature. Nevertheless air-engines of slight power are frequently used—for example, in laboratories—to drive a propeller maintaining circulation of water in a vessel whose temperature is wished to be kept constant.

Air-engines have recently been constructed, in which solar rays, concentrated by means of an arrangement of mirrors, are utilised as the source of heat. These have been called *solar* engines. For a very different kind of air-engine, see COMPRESSED AIR MOTORS.

Aire-sur-l'Adour. See AIRE.

Aire-sur-la-Lys, a fortified town in the French department of Pas-de-Calais, on the Lys, and at the junction of three canals, 37 miles W. of Lille by rail. It has one fine church, St Pierre, some cotton and woollen manufactures, and a considerable trade. Pop. 8200.

Air-force. See BALLOONS AND AEROPLANES.

Air-gun. There are several forms of this weapon, but it is commonly made like a fowling-piece or musket, with lock, stock, and barrel. In one of the simplest kinds there is an air-chamber placed above the barrel, and the two communicate by a valve opening just behind where the bullet is placed. By means of a syringe in the stock, the air is condensed in the chamber. On pulling the trigger the valve opens, and immediately the bullet is projected with considerable force by the elasticity of the compressed air behind it. In air-guns, the reservoir of condensed air is usually very large in proportion to the tube which contains the ball, so that its elastic force is not greatly diminished by expanding through it. These guns commonly propel a bullet to a distance of from 60 to 80 yards. One form of air-gun contains several bullets in a receptacle or channel under the barrel; by the movement of a cock or lever, one of these bullets can readily be shifted into the barrel; and thus several successive discharges can be made after one loading—on a principle somewhat analogous to that of the revolving pistol. Some varieties of air-guns have the condensing syringe detached, by which means greater condensation of air may be produced; this done, the air-chamber is again attached to the barrel. A pressure of as much as 500 atmospheres has been attained with a powerful condenser, but even this is only about half the elastic force of fired gunpowder. Those air-guns which present the external appearance of stout walking-sticks, and are thence called *air-canes*, have a chamber within the handle for containing condensed air, which can be unscrewed, and subjected to the action of the condensing syringe. The air-gun was known in France more than two centuries ago; but the ancients were acquainted with some kind of apparatus by which air was made to act upon the shorter arm of a lever, while the larger arm impelled a bullet. Several English patents were taken out for peculiar forms of air-guns in the last quarter of the 19th century. They are sometimes made in the form of simple walking-sticks (their real nature being disguised), and carried for personal defence in an emergency. Inventions for using compressed air to fire large shots with pieces of ordnance were patented by Bessemer (1867) and others. Lieutenant Zaluski of the U.S. army invented in 1886 a large 'pneumatic gun' for throwing shells containing dynamite. The gun was of iron, 60 feet long, 8 inches in the bore, and $\frac{1}{2}$ inch thick. Air at 1000 lb. pressure, supplied from eight reservoirs, each 20 feet long by 12 inches in diameter, was admitted through one of the trunnions to a chamber in the gun just behind the projectile. An automatic valve permitted a volume of the compressed air to escape into this chamber. A war-vessel was equipped with three of these guns and used by the Americans in the Cuban war of 1898. They have been used for harbour defence; and a pneumatic field-gun for throwing shells filled with explosive gelatine, with a range of 3600 yards, was used with some effect in the Cuban war.

Air-lock. When hollow cylinders (*Caissons*, q.v.) of iron are used for founding the piers of bridges under water, it is now the custom to use condensed air in them, the pressure of which does not generally exceed two atmospheres beyond the ordinary atmospheric pressure. This iron shell is open at the bottom, but air-tight and water-tight at all other points; thus water is prevented from rising in it. As part of the arrangement, it is necessary to have at the top of the caisson or elsewhere a chamber, called an *air-lock*, to serve for the exit and entrance of men and materials. This comparatively small chamber has an outer and an inner door. The outer door is shut after a man

enters, and just then the air around him is at its ordinary pressure. But before the inner door is opened, the air in this chamber is compressed like that in the caisson, and he can then descend to his work.

Airolo, an Italian-Swiss village, in the upper valley of the Ticino, and 150 yards from the southern mouth of the great St Gothard Tunnel. Pop. 2000.

Air-plants. See EPIPHYTES.

Air-pump, an instrument for removing the air from a vessel. The essential part is a hollow brass or glass cylinder, in which an air-tight piston is made to move up and down by a rod. From the bottom of the cylinder, a connecting tube leads to the space which is to be exhausted. This space is usually formed by placing a bell-glass, called the receiver, with edges ground smooth, and smeared with lard, on a flat, smooth plate or table. When the piston is at the bottom of the barrel, and is then drawn up, it lifts out the air from the barrel,

Air-pump.

and a portion of the air under the receiver, by its own expansion, passes through the connecting tube, and occupies the space below the piston, which would otherwise be a vacuum. The air in the receiver and barrel is thus *rarefied*. The piston is now forced down, and the effect of this is to close a valve placed at the mouth of the connecting tube, and opening inwards into the barrel. The air in the barrel is thus cut off from returning into the receiver, and, as it becomes condensed, forces up a valve in the piston, and escapes into the atmosphere. When the piston reaches the bottom, and begins to ascend again, this valve closes; and the same process is repeated. Each stroke diminishes the quantity of air in the receiver. Theoretically, there must always be a portion left, though that portion may be rendered less than any assignable quantity; and, apart from leakage, the process is limited by the pressure of the remaining air being insufficient to open the valves. The degree of rarefaction is indicated by a *gauge* on the principle of the barometer. By means of the partial vacuum formed by the air-pump a great many interesting experiments can be performed, illustrating the effects of atmospheric pressure, and other mechanical properties of gases. The air-pump was invented by Otto Guericke (q.v.), 1654; and though many improvements and varieties of structure have been since devised, the principle of all, even the modern rotary, mechanically very

different, types, or the types in which a falling column of liquid is used, is the same. In the old type two barrels are generally used, so as to double the effect of one stroke. The inflater used for bicycle and motor pneumatic tyres is also an air-pump, used with the converse purpose of forcing in air. For other uses of compressed air, see BORING, BRAKE, DIVING.

Air-sacs are outgrowths from the lungs of birds. They lie in the chest and abdominal region, are in direct connection with the branches of the bronchial tubes, and are usually nine in number. The air entering those reservoirs is warmed, and must to a slight extent lessen the specific gravity of the bird. The air-sacs increase

Diagram of Lungs and Air-sacs of the Pigeon:

Tr, trachea; l, lungs; a, peritracheal air-sac with its diverticula (b and c) into the humerus (d) and between the pectoral muscles; e, intermediate air-sacs; f, abdominal or posterior air-sacs.

(From Claus, after Heider.)

the respiratory content, secure more thorough aeration of the lungs, and assist in internal perspiration, thus helping in the regulation of the body temperature. In most birds some of the air-sacs communicate with an extensive series of air-spaces in the bones and under the skin. Hints of these air-sacs, so characteristic of birds, are to be found in some reptiles.

Air-ship. See BALLOONS AND AEROPLANES.

Airy, SIR GEORGE BIDDELL, K.C.B., Astronomer Royal, was born at Alnwick, 27th July 1801. In 1819 he went to Trinity College, Cambridge, of which he was elected scholar (1822) and fellow (1824), having the year before come out senior wrangler. In 1826 he was elevated to the Lucasian professorship of mathematics, which he rescued from the reproach of being a sinecure, by delivering a course of public lectures on experimental philosophy; in 1828, he was made professor of Astronomy, and had the management of the newly elected Cambridge Observatory intrusted to him; and in 1836 he succeeded Pond as Astronomer Royal. By his introduction of new or more perfect scientific instruments, and of more rapid methods of calculation; by his researches in magnetism, meteorology, photography, &c. he deservedly obtained the reputation of being one of the ablest and most indefatigable of modern savants. To observe total solar eclipses, he visited Turin (1842), Gothenburg (1851), and Pöbes, in Spain (1860); he was president of the Royal Society (1871-73); and in 1871 he became a Companion (Civil) of the Bath; in 1872, a Knight Commander. Among his works have been *Astronomical Observations at Cambridge and Greenwich* (20 vols. 1829-57); *Catalogue of 2156 Stars* (1849); *Ipswich Lectures on Astronomy* (1851); *Algebraical and Numerical Theory of Errors of Observations* (1861); *Undulatory*

Theory of Optics (1866); *Atmospheric Chromatic Dispersion* (1869); *Magnetism* (1871); and *Notes on the Earlier Hebrew Scriptures* (1876). He retired on a pension in 1881, and died in London, 2d January 1892.

Aisle (from Lat. *ala*, 'a wing') means any lateral division of any part of a church, whether attached to the nave, choir, or transept. The number of aisles varies in different churches. In England, as a rule, there is only one on each side of the nave or choir; in most foreign countries, there are frequently two, and at Antwerp and elsewhere there are three. The continental edifices, it would seem, have antiquity in their favour for this arrangement (see **BASILICA, CHURCH**). The word is often incorrectly applied to the passage between church pews.

Aisle—Melrose Abbey.

Aisne, a French river, flowing 150 miles north-westward and westward through the departments of Maine, Ardennes, Aisne, and Oise, till it falls into the river Oise, above Compiègne. It gives name to a battle (Sept.-Oct. 1914) in the Great War.

Aisne, a department in the north of France, comprising parts of Picardy, Brie, and the Isle of France; area, 2839 sq. m. Hilly in the south, level in the north, it belongs to the basin of the Seine, and is watered by the rivers Aisne, Maine, and Oise, and by other navigable streams and canals. The soil is fertile, the chief products being grain, hay, wine, and cider. It is the seat of considerable woollen and other manufactures. Laon is the capital. Pop. (1901) 534,204; (1921) 421,515.

Aiwalyk (*Awaly*), a seaport in NW. Asia Minor, on the Gulf of Ediemid (Adiamyti); pop. 35,000, most of whom are Greeks. There is a considerable trade in olives and oil.

Aix, a French town, formerly the capital of Provence, in the department of Bouches-du-Rhône, 20 miles N. of Marseilles. It is believed to have been founded by the Roman consul, C. Sextius (120 B.C.), on account of the mineral springs in the neighbourhood, and thence to have got the name *Aqua Sextia*. Aix is the seat of an archbishop, and possesses a college with three faculties, and a public library with 150,000 volumes and 1100 MSS. The baptistery of the cathedral is believed to have been originally a temple of Apollo. There is also an old clock-tower with a quaint mechanical clock. The industry of this again flourishing town consists chiefly in the cultivation of the olive, in cotton-spinning, leather-dressing, and trade in oil, wine, almonds, &c. The warm springs are slightly sulphurous, with a temperature from 90° to 100° F., clear and transparent as the purest well-water, almost free from smell, yet with a slightly bitter taste. The field on which Marius defeated the Teutones lies in the plain between Aix and Arles. In the middle ages, under the Counts of Provence (q.v.), Aix was long the literary capital of southern Europe. Pop. 30,000.

Aix-la-Chapelle (Ger. *Aachen*), the capital of a district in Rheinland, is situated in a fertile hollow, surrounded by heights, and watered by the Wurm, 39 miles W. by S. of Cologne. Pop. (1867)

67,923; (1910) 156,044; (1919) 145,748, not 7 per cent. Protestants. Aix-la-Chapelle is the centre of a valuable coal district, and of numerous thriving manufactories, especially for spinning and weaving woollen fabrics, and for needle and pin making. There are also immense manufactures of machinery, bells, glass buttons, chemicals, and cigars. As a principal station on the Belgian-Rhenish railways, Aix is an important centre of trade. The city is rich in historical associations. It emerges from historical obscurity about the time of Pepin; and Charlemagne founded its world-wide celebrity. Whether it was his birthplace is doubtful, but in 814 it became his grave. In 796 he had rebuilt the imperial palace, as well as the chapel in which Pepin had celebrated Christmas in 765. The present town-house was built in 1353 on the ruins of the palace; the chapel, after being destroyed by the Normans, was rebuilt by Otho III. in 983, and forms the nucleus of the cathedral. This ancient cathedral is in the form of an octagon, which, with various additions round it, forms on the outside a sixteen-sided figure. In the middle of the octagon, a stone, with the inscription 'Carolo Magno,' marks the site of the grave of Charlemagne. In 1215 Frederick II. caused the remains of the emperor to be inclosed in a costly shrine. In the newer part of the building are kept the so-called 'great relics,' which, once in seven years, are shown to the people in the month of July, and which attracted thousands of strangers in 1909. Much has of late years been done to restore this venerable pile. The columns brought by Charlemagne from the palace of the Exarch at Ravenna, to decorate the interior of the octagon, had been carried off by the French; but most of them were restored at the peace of Paris, and replaced in 1846. The town-house, adorning the market-place, is flanked by two towers older than itself, which suffered much by fire in 1883. Its coronation-hall, 162 feet long by 60 wide, in which thirty-five German emperors and eleven empresses have celebrated their coronation banquet, has been restored to its original form, and the walls have been decorated with frescoes of scenes from the life of Charlemagne. Before the town-house stands a beautiful fountain, with a bronze statue of Charlemagne. As a town, Aix-la-Chapelle has recently been much improved. It now possesses broad streets, many fine public buildings, tasteful churches, and luxurious hotels; and from being a quiet old city of historical interest, has become a busy centre of manufacturing industry.

The name of the place is derived from the springs, for which it has been always famous. Aa or Aachen is derived from *aach*, an old German word for water; the French *Aix* is the Latin *aque*, while the *Chapelle* in the French name is the chapel of the palace. Charlemagne granted extraordinary privileges to this city. The citizens were exempted, in all parts of the empire, from personal and military service, from imprisonment, and from all taxes. In the middle ages, this free imperial city contained more than 100,000 inhabitants. The emperors were crowned in Aix-la-Chapelle from Louis the Pious to Ferdinand I. (813-1531). Seventeen imperial diets and eleven provincial councils were held within its walls. The removal of the coronations to Frankfurt, the religious contests of the 16th and 17th centuries, a great fire which in 1656 consumed 4000 houses, combined with other causes to bring into decay this once flourishing community. In 1793, and again in 1794, Aix-la-Chapelle was occupied by the French. By the treaties concluded at Campo Formio and Lunéville, it was formally ceded to France, until in 1815 it fell to Prussia.

The MINERAL SPRINGS of Aix-la-Chapelle, of

which six are hot, and two cold, were known in the time of Charlemagne, and have been frequented since as early as 1170. The temperature of the hot springs varies from 111° to 136° F. They chiefly act on the liver, and on the mucous surfaces and skin, and are therefore efficacious in cases of gout, rheumatism, cutaneous diseases, &c. The cold springs are chalybeate, and not so copious.

TREATIES OF PEACE AND CONGRESS OF AIX-LA-CHAPELLE.—The first Peace of Aix-la-Chapelle (1668) ended the war carried on between France and Spain for the possession of the Spanish Netherlands (see LOUIS XIV.).—The second Peace of Aix-la-Chapelle (1748) concluded the war respecting the succession of Maria Theresa to the empire (see SUCCESSION WARS). In general, the possessions of the several states remained as before the war. Austria ceded Parma and Placentia to the Spanish infanta, Philip; and the possession of Silesia was guaranteed to Prussia. The privilege of the Assiento (q.v.) was anew confirmed to England for four years, and the Pretender was expelled from France.

The Congress of Aix-la-Chapelle was held in 1818, for regulating the affairs of Europe after the war. It began on the 30th September, and ended on the 21st November. Its principal object was the withdrawal from France of the army of occupation, 150,000 strong, as well as the receiving of France again into the alliance of the great powers. The emperors of Russia and Austria, and the king of Prussia, were present in person. The plenipotentiaries were—Metternich, Castlereagh and Wellington, Hardenberg and Bernstorff, Nesselrode and Capo d'Istria, with Richelieu on the part of France. The five great powers assembled signed a protocol announcing a policy known as that of the 'Holy Alliance' (q.v.).

Aix-les-Bains (*Aque Gratiæ*), a small town in the French department of Savoy, in a delightful valley near Lake Bourget, 8 miles N. of Chambéry. It was a much frequented bathing-place in the time of the Roman empire, and among its numerous remains of ancient times are the arch of Campanus, the ruins of a temple, and of a vapour-bath. The sulphurous hot springs, two in number, have a temperature of 109° and 113° F. They are drunk and used as baths. Pop. 9000.

Aizoaceæ. See MESEMBRIACEÆ.

Ajaccio, since 1811 the capital of Corsica, on the west side of the island, at the head of the Gulf of Ajaccio. Transferred to its present site in 1435, it has a fine cathedral, completed in 1585, and a spacious harbour, protected by a citadel; but its special interest is as the birthplace of Napoleon. There is a statue of him as First Consul (1850), and a monument of the emperor on horseback, surrounded by his four brothers (1865). The house of the Bonapartes, the 'Casa Bonaparte,' is now national property. The chief employments are the anchovy and pearl fisheries, and the trade in wine and olive-oil, which the neighbourhood produces in abundance, and of good quality. Of late years, Ajaccio has become a winter-resort for consumptive patients. Pop. 23,000.

Ajaigarh, a hill-fort of India, in the United Provinces, 130 miles WSW. of Allahabad. Perched on a steep granite crag, it was captured by the British in 1809. Within its walls are two great masses of ruined Jain temples, covered with the most elaborate sculptures.

Ajanta, a village in the extreme NW. of the Nizam's Dominions, 50 miles NW. of Ellora (q.v.), is famous for its old Buddhist cave-hermitages and halls, many of them richly adorned with frescoes that since their discovery in 1817 have been allowed

to go to ruin. They date from 200 B.C. to A.D. 700. See Havell's *Indian Sculpture and Painting* (1908), and *Ajanta Frescoes*, by Lady Herringham and others (1915).

Ajax (Gr. *Aias*), the name of two Greek heroes in the Trojan war: (1) Ajax the Less, son of Oileus, king of the Locrians. He led forty ships to Troy, and was famous for swiftness of foot and skill in hurling the spear. At the capture of the city he excited the anger of Pallas by an insult offered in her temple to Cassandra, and on the homeward voyage he was overtaken by the vengeance of the goddess, and swallowed up by the waves.

(2) Ajax the Greater, son of Telamon, king of Salamis, and by his mother's side a grandson of Æacus. He sailed against Troy with twelve ships, and is represented by Homer as, next to Achilles, the bravest and handsomest of the Greeks. After the death of Achilles, Ajax and Ulysses contended for the arms of the hero, and the prize was adjudged to Ulysses, which threw Ajax into such a state of rage and despair that he killed himself with his sword. This is the subject of one of the noblest of the extant tragedies of Sophocles.

Ajmere (*Ajmir*), an ancient city of Rajputana, capital of a British district, 228 miles W. by S. of Agra by rail. It stands in a picturesque and rocky valley at the foot of Taragarh hill, and is surrounded by a stone wall with five gateways. It is rich in buildings of antiquarian interest, and has many spacious streets, and fine residences, besides several mosques and temples of very massive architecture. The Dargah Khwaja Sahel, or tomb of the Mussulman saint, Muin-ud-din Chishti, who died 1239, is an object of pilgrimage. The Mayo College, a 'chiefs' college,' has been called an aristocratic Indian Eton. The principal export is cotton. Pop. 114,000, less than half Mohammedans.

Ajodhya, an ancient city of Oudh, on the right bank of the Gogra, adjacent to Fyzabad (q.v.). It was the capital of the kingdom of Kasala, and fell with the Solar line of kings. The Ramayana describes its magnificence. Its site, which is said to have extended to 96 sq. m., is marked by heaps of ruins, overgrown with jungle; but there is a small modern town, and the great fair of Ramnami yearly attracts half a million of pilgrims.

Akabah, a haven at the head of the Gulf of Akabah, the north-eastern horn of the Red Sea (q.v.). It is the ancient *Alana*, the Biblical *Elath*, a town of the land of Edom.

Akbar (i.e. 'the great,' his proper name being Jelal-ed-din-Mohammed), Mogul emperor of India, the greatest Asiatic monarch of modern times. His father, Humayun, was deprived of the throne by usurpers, and had to retire for refuge into Persia; and it was on the way thither, in the town of Amarkot, that Akbar was born in 1542. Humayun recovered the throne of Delhi after an exile of twelve years; but died within a year. The young prince at first committed the administration to a regent-minister, Beiram; but finding his authority degenerating into tyranny, he shook it off at the age of eighteen, and took the power into his own hands. At this time only a few of the many provinces once subdued by the Mongol invaders were actually subject to the throne of Delhi; in ten or twelve years, Akbar's empire embraced the whole of India north of the Vindhya Mountains, but in Southern India he was less successful. He conquered and conciliated all the independent Mohammedan and Hindu princes of Northern India from Cashmere to Behar; and although a great conqueror, was yet a greater ruler. The wisdom, vigour, and humanity with which he organised and administered his vast dominions are unexampled in the East. He

promoted commerce by constructing roads, establishing a uniform system of weights and measures, and a vigorous police. He exercised the utmost vigilance over his viceroys of provinces and other officers, to see that no extortion was practised, and that justice was impartially administered to all classes of his subjects. For the adjustment of taxation, the lands were accurately measured, and the statistics taken, not only of the population, but of the resources of each province. For a born Mohammedan, the tolerance with which he treated other religions was wonderful. He gave the Hindus freedom of worship, though he prohibited cruel ordeals and the burning of widows. He was fond of inquiries as to religious beliefs; and Portuguese missionaries from Goa were sent at his request to give him an account of the Christian faith. He even attempted to promulgate a new religion of his own, an eclectic kind of deism or natural religion; but it never took root. Literature received the greatest encouragement. Schools were established for the education both of Hindus and Mohammedans; and numbers of Hindu works were translated from Sanskrit into Persian. Abul-Fazl, the able minister of Akbar, has left a valuable history of his master's reign, entitled *Akbar-nameh*. After a memorable reign of nearly fifty years, Akbar died in 1605, and was buried in a noble mausoleum at Sikandra, near Agra. See Malleson's *Akbar* (1890).

Akee (*Cupania* or *Blighia sapida*), a fruit tree belonging to the natural order Sapindaceæ (q.v.), a native of Guinea, introduced into Jamaica in the eighteenth century. It grows to the height of 20-25 feet or upwards, with numerous branches and alternate pinnate leaves, resembling those of the ash. The flowers are small, white, on axillary racemes; the fruit is about the size of a goose's egg, with three cells and three seeds, and its succulent aril has a grateful subacid flavour. The fruit is little inferior to a nectarine. The akee sometimes produces fruit in hot-houses in Britain.—The AKI of New Zealand is a totally different plant, *Metrosideros buxifolia*, of the natural order Myrtaceæ; at first a shrub, which climbs by the aid of lateral roots, it thus attains the summit of the loftiest trees, which ultimately decay, but not until the parasite is strong enough to stand by itself.

A Kempis, THOMAS. See KEMPIS.

Akenside, MARK, poet and physician, was born in 1721, at Newcastle. The son of a butcher, at the age of seven he was accidentally lamed for life in his father's shop. He was destined for the Presbyterian Church, and in 1739 was sent to study theology at Edinburgh, but soon abandoned it for medicine. He graduated as a physician at Leyden in 1744, and practised at Northampton, then at Hampstead, and finally in London. His success as a practitioner was never very great, owing to his haughty and pedantic manner; but at Leyden he had formed an intimacy with Jeremiah Dyson, and this rich and generous friend allowed him £800 a year. He died in London, June 23, 1770, having nine years earlier been appointed one of the physicians to the queen. Some of his medical treatises possess considerable merit. He contributed verses to the *Gentleman's Magazine* as early as 1737; and in 1744 appeared his *Pleasures of the Imagination*, a didactic poem, which was begun in his 18th year, and to which is owing whatever celebrity attaches to his name, though his *Hymn to the Naiads* (1746) is his finest production. In 1772, Dyson published his poetic works, the best edition of which is that by Dyce, with Life (1834). In *Peregrine Pickle*, Smollett has sketched Akenside to the life, as the pedant who gives an entertainment after the manner of the ancients. Akenside has little originality. The reader is carried along

by 'abundance of gay colouring and well-sounding words, filling the eye oftener than the imagination, and the ear oftener than either.' See his *Life* by Bucke (1832); and for Hannah More's enthusiastic encomium of his 'magnificent blank verse,' *Celebs in Search of a Wife*.

Akers, BENJAMIN PAUL, an American sculptor, born near Portland, Maine, U.S., 10th July 1825; died at Philadelphia, 21st May 1861. For a time engaged in a printing-office, he studied sculpture, and after opening a studio in Portland, executed busts of Longfellow and others. He visited Italy in 1851-2, and again in 1855. His finest works were executed at Rome, such as 'Una and the Lion,' 'St Elizabeth of Hungary,' 'Dead Pearl-diver,' and a head of Milton; the last two of which have been described in Hawthorne's *Marble Faun*, called in England *Transformation*.

Akhalzikh, or AKISKA, a town of the Georgian Republic, 110 miles W. of Tiflis, on an affluent of the Kur. It is the seat of a Greek archbishopric, and maintains an active trade. Pop. 23,000, two-thirds Armenians.

Ak-Hissar, a town of Asia Minor, 52 miles N.E. of Smyrna; the ancient *Thyatira*, where was one of the Seven Churches of Asia. Relics of antiquity abound; cotton goods and dyestuffs are exported. Pop. 12,000.

Akhlat, or ARDISH, in Armenia, on the NW. shore of Lake Van, beside the ruins of Chelat, once the home of Armenian princes; pop. 4000.

Akhmaton, or AKHUNATEN, was the name adopted by the heretic Pharaoh, Amenhotep IV. (see EGYPT), who in the 14th century B.C. renounced the old gods and established a purified solar cult, free of tribal or national limitations. In the enthusiastic monograph of Mr Weigall (1910; new ed. 1922), he is 'the world's first idealist,' and his religion the first universal religion.

Akhtyrka, a town of Ukraine, 58 miles NW. of Kharkoff, on a small affluent of the Dnieper; pop. 23,500.

Akiba, BEN JOSEPH, a Jewish rabbi of the 2d century, who studied under Rabbi Eliezer, and was himself one of the principal fathers of the Mishna (q.v.). Born in Syria, he travelled through the empire, and became the most eminent teacher of his people and time. He systematised the Jewish traditions, and his *Mishna of Rabbi Eliezer* was the foundation of the religious code, although the work itself has not been preserved. Akiba entered heartily into the revolt of Bar-Cochba (q.v.), and on his overthrow was put to death with great tortures by the Romans (135 A.D.).

Akiska. See AKHALZIKH.

Akjerma, or AKKERMAN (Rum. *Cetatea Alba*; Polish *Bielogrod*), a town of Bessarabia, on the Black Sea, at the mouth of the Dneister, with a citadel and a harbour accessible to large steamers. Soap and candles are made, fish salted, and a good wine grown. The treaty concluded here in 1826 between Russia and Turkey secured to Russia the free navigation of the Black Sea, and new privileges for Moldavia, Wallachia, and Serbia. Pop. 40,000—Russians, Greeks, Armenians, and Jews.

Akka, a wandering tribe of dwarfs in Central Africa, made known by Schweinfurth in 1874, and visited in 1882 by Junker. They are also called *Tiki-tiki* by their neighbours the Nyamnyam. Their territory lies some two days' journey south of the Monbuttu, west of Albert Nyanza. Their average height does not exceed 4 feet 10 inches, and their projecting jaw and protruding lips give them a painfully ape-like appearance. They are timid and difficult of approach, and shun communication with strangers. They live entirely

by hunting, keeping no domestic animals but poultry.

Akkad. See ACCAD.

Akmolinsk, a province of Western Siberia, organised in 1868. Pop. in 1910 about 1,500,000. Akmolinsk, the capital, 300 miles SW. of Omsk, was founded in 1862, and has a pop. of 20,000.

Akron, a city of the state of Ohio, United States, the capital of Summit County. It is situated 36 miles south of Cleveland, on the Little Cuyahoga, which falls into Lake Erie, and at the junction of the Ohio and Erie Canal with the Pennsylvania and Ohio Canal, at the highest point in the course of the former canal, whence its name (Gr., 'a summit'). It is also at the intersection of two railways. Akron is the chief centre of the world's rubber manufacture. To this it owes its rapid growth in population. It has woollen factories, flour-mills, and other works, driven by ample water-power. Near the town are large supplies of fireclay. It was first settled in 1825. Pop. (1870) 10,006; (1890) 27,601; (1910) 69,067; (1920) 208,435.

Aksakof, IVAN SERGEJEVICH, a member of a Russian family of *littérateurs*, born October 7, 1823, wrote lyrics, but is best known as the representative of panslavism. From 1880 till his death, February 8, 1886, he exerted much influence as editor of the recognised organ of his party.

Ak-shehr (*White City*), a city of Asia Minor, 65 miles NW. of Konia, and 5 miles S. of the salt lake of Ak-shehr; pop. 14,500.

Ak-su, a town of Chinese Turkestan, 260 miles NE. from Yarkand, on an affluent of the Tarim, and at the southern base of the Thian-shan Mountains. It was formerly the capital of a separate khanate; in 1867 it became a part of the state of Eastern Turkestan, under Yakooob Beg, but was conquered again by China in 1877. It is celebrated for its manufactures of cotton cloth and saddlery, and is much resorted to by caravans, as an entrepôt of commerce between Russia, Tataria, and China. Pop. 20,000, besides a Chinese garrison as numerous.

Akyab, a town of Burma, headquarters of Arakan division and Akyab district, is situated on the eastern side of the island of Akyab, at the mouth of the Kuladan River. In 1826, before the annexation of Akyab, it was a mere fishing-village; it is now a great rice port. Savage Island, with a lighthouse, shelters the excellent harbour. Pop. 38,000.—The district (5136 sq. m.), the northernmost in Lower Burma, consists of a rich and well-watered alluvial plain with forest-clad hill-country inland. The population is about half-a-million.

Alabama, one of the United States of North America, is popularly known in the Union as the Cotton State. It extends northward from the Gulf of Mexico some 330 statute miles; the state of Tennessee being on the north, Georgia on the east, Florida and the Gulf of Mexico on the south, and Mississippi on the west; 30° 13' to 35° N. lat., 84° 53' to 88° 35' W. long. The seaboard has an extent of about 60 miles, excluding the shores of Mobile Bay and the minor sinuosities. The maximum breadth of the state is 202 miles. The area, as officially estimated, is 52,250 sq. m., a little more than that of England, exclusive of Wales.

The state has four strongly marked natural divisions. The southernmost portion, known locally as the Piny Woods, having an average breadth from north to south of about 125 miles, is of tertiary and quaternary formation, with a surface covering of sandy drift. In this region are extensive forests of the yellow pine (*Pinus australis*), extremely valuable for its timber, as well as for its yield of turpentine, rosin, tar, and turpentine-oil.

Near the rivers are swamps densely timbered with valuable cypress (*Taxodium distichum*). The pine-region has for the most part a light soil. North of this coast-region comes the Cane-brake, or Black Belt, of extremely fertile cretaceous (rotten limestone) soils. A part of this belt consists of open ('bald') prairie. Good water is only procurable in some sections of this belt by means of artesian wells. Cotton is the staple product of this tract. North of the Black Belt lies the great mineral region of the state. This district is in reality the south-west terminal portion of the great Appalachian range of mountains, here, for the most part, merely broken ridges and lines of hills, among and to westward of which are found vast bodies of good coal, side by side with beds of iron-ore and limestone of enormous extent. In the north-east, especially E. of the Tennessee River, there is a mountainous tract, a continuation of the central iron district. The iron industry has been greatly developed since 1895, and the cheapest pig-iron in the world is now made here: in 1896, 65,000 tons were exported to England; in 1897, 218,633; and from 1899 onwards, over 1,000,000 annually.

The large navigable rivers, Alabama (312 miles long by survey) and Tombigbee, unite in the south-west part of the state to form the short Mobile River, which flows into Mobile Bay, near the town of Mobile. The greater part (some 18,000 sq. m.) of the state is drained by this river-system. The Black Warrior is the largest affluent of the Tombigbee; and the Cahawba (115 miles long), Coosa (335 miles long), and Tallapoosa are important tributaries of the Alabama. These main streams, with some others, are in general either navigable or may be fitted for navigation, while their minor tributaries afford vast water-power, as yet very imperfectly utilised. In the north, the great river Tennessee traverses the state, but its importance for navigation is lessened by the 'Muscle Shoals,' an extensive series of rocks and rapids, which can only be passed at very high water. Engineering works for surmounting these obstructions have been undertaken.

The mineral resources of the state are varied and important. Besides the valuable coal and iron deposits already noticed, Alabama has extensive beds of fine marble, statuary granite, and building stones in large variety. Some gold is mined in Cleburne and Talladega counties. Medicinal springs are found in nearly all parts of the state.

Among the leading productions of Alabama are cotton, maize, oats, wheat, and sweet potatoes. Rice and sugar-cane are grown in the southern counties. Apples, peaches, grapes, figs, pears, and oranges (the latter in the south) are among the fruits successfully grown. Tobacco is cultivated in the north. In general, the soils of this state are highly fertile; but in the pine barrens, and in the mountain region, there are large tracts not naturally productive.

The climate is warm but equable, the hill country and the pine forests (except near the swampy districts) are remarkably healthful; but the fertile Black Belt is not regarded as a safe place of summer or autumnal residence for unacclimatised persons. Remittent and bilious fevers are not unfrequent in this region. The rainfall is abundant, and is well distributed throughout the year; but some of the porous limestone soils are not retentive of water, and the crops often suffer from drought. The small rivers of the central region are remarkably liable to floods or freshets.

The only seaport of Alabama is Mobile; but the approach to that town is not practicable for large ships; hence Pensacola in Florida has become the principal shipping-point for the lumber and forest products of Alabama; while Savannah in Georgia, New Orleans in Louisiana, and Charles-

ton in South Carolina, ship a large part of the cotton crop. The foreign trade in Alabama coal promises to become large.

The manufacturing interests of Alabama are rapidly developing. Pig-iron can be produced here, it is confidently asserted, more cheaply than in any other part of America; coal, iron, and limestone occurring in close propinquity. Cotton goods are largely manufactured. Much lumber is saved in the forest region, which also affords considerable amounts of tar and naval stores.

Alabama was settled by the French, who established a fort on the Mobile River in 1702. The city of Mobile was founded in 1712. The French settlements were regarded as a part of the Louisiana colony until 1763, when the country was ceded to Great Britain by the Treaty of Paris. What is now Southern Alabama was ceded to Spain in 1783, and became a part of West Florida, while the rest of the country was given up to the United States, which, however, after 1803, claimed the Spanish part under the Louisiana purchase; but Spain did not concede this claim until 1819. Alabama was made a state of the Union in 1819, and seceded, with most of the other slave states, in 1861. After the civil war of 1861-65, the state passed through a long season of social and business depression; but since 1880 the outlook for Alabama is one of unusual promise.

The pop. of Alabama in 1800 was only 1250; (1830) 309,257; (1860) 964,201; (1880) 1,262,505; (1890) 1,513,017; (1910) 2,138,093; (1920) 2,348,174. The chief towns were, in 1920, Mobile (61,000), the only seaport, with a large shipping trade; Birmingham (179,000), one of the leading iron manufacturing cities of the country; Montgomery (43,500), capital of the state, with a large trade in cotton; Bessemer (19,000); Anniston (18,000), in the iron-making region; Selma (16,000); and Gadsden (15,000).

Alabama was the name of an armed vessel of the Confederate States, which inflicted terrible injury upon the shipping of the Northern States of the American Union during the civil war. She was built by Messrs Laird & Sons at Birkenhead, and was a screw steam-sloop of 1040 tons register, built of wood, and for speed rather than strength. Captain Semmes, who was appointed commander, superintended her equipment, and was enjoined by the Confederate government to keep the destination of the vessel as secret as possible, and carefully to avoid any infringement of law which would give the British government a pretext for seizing her. The destination of 'No. 290,' as she was called, was so well concealed, that the vessel was nearly finished before it was suspected by the agents of the United States. It had heretofore been held lawful to build vessels (not being manifestly war-vessels) for a belligerent in neutral ports, and lawful to purchase guns and stores in neutral ports, though they might be for the equipment of vessels thus built. What had been held unlawful was the equipment with guns and warlike stores, of a vessel built for a belligerent in a neutral port *previous* to her leaving the neutral jurisdiction. Captain Semmes did not intend to equip his vessel at Birkenhead; but the United States minister called upon the British government to detain 'No. 290,' submitting some evidence that she was intended for a Confederate war-vessel. The British government consulted the crown lawyers, who at first thought the evidence of destination insufficient; but after some delay, an opinion favourable to the detention of the vessel was at length given. The English lawyers were of opinion that there had been no infringement of the law, but that a case had been presented which the British government was

bound to submit to a court of law. It was too late. 'No. 290' was gone. The builders, aware of the danger of a seizure, had hastened their work, and the vessel, though unfinished, under pretence of a trial trip made her way down the Mersey to Moelfra Bay, where the work remaining to be done was soon finished. On the morning of the 31st July 1862, warning having been given that she was to be seized that day, 'No. 290' steamed away from the British coast and made for Terceira, one of the Azores, where she shipped her armament and stores, and by the 24th of August was ready for sea; and now Captain Semmes produced his commission to the sailors, named the vessel the *Alabama*, and hoisted the Confederate flag. The vessel made her first capture on the 5th of September. Within eleven days of that date, she captured and burned property the value of which exceeded her own cost.

Off the American coast, the *Alabama* gave battle to the United States gunboat *Hatteras*, an old vessel, and sunk her after a few broadsides. Her subsequent history consists of a monotonous succession of captures made in different seas, her prizes being merchant-vessels incapable of resistance, which were burned, as there was no port available for the disposal of her prizes, or, when there was convincing evidence of the neutral ownership of the cargo, which did not often happen, liberated upon bond. She captured in all 65 vessels; and the value of the property she destroyed was estimated at \$4,000,000. It was, however, by the heavy insurance for war-risks to which she subjected the shipowners of the United States, and still more by the difficulty she caused them in getting freights, that the *Alabama's* career inflicted the greatest injury. After a cruise in the eastern seas, she entered, on the 11th of June 1864, the French port of Cherbourg to refit. Within a few days, the United States steamer *Kearsarge*, commanded by Captain Winslow, arrived at Cherbourg, and made a demonstration which the officers of the *Alabama* regarded and accepted as a challenge. The fight took place on Sunday, the 19th of June, outside the port of Cherbourg. Before the fight had lasted an hour, Captain Semmes found his ship was sinking, and gave orders to pull down his flag. See Admiral Semmes, *Service Afloat* (Lond. 1887).

The 'Alabama Question' was raised in the winter of 1862-63, when Mr Seward declared that the Union held itself entitled to demand full compensation for the damages inflicted on American property; and the divergence of view more than once threatened to issue in the gravest consequences to both nations. In 1871 a commission met at Washington; and by a treaty concluded there, provision was made for referring this claim to a tribunal composed of five arbitrators, of whom the Queen, the president of the United States, the king of Italy, the president of the Swiss Confederation, and the emperor of Brazil, were each to appoint one. The tribunal met at Geneva in December 1871, and by its final award Great Britain was ordered to pay a sum of £3,229,166; this sum covering also some responsibility for the depredations of the ships *Florida* and *Shenandoah*. The claim for indirect damage to American commerce was dropped. A court of commissioners was appointed by congress to adjudicate on 'Alabama claims,' sat from July 1874 to December 1876, and awarded \$9,316,120 (£1,863,224). A second court (1882-86) disposed of the remainder of the money to further claims.

Alabaster, a variety of Gypsum (q.v.) or Selenite (q.v.). Chemically, these are all forms of the hydrated sulphate of calcium (hydrated sulphate of lime). Anhydrite (q.v.) is anhydrous sulphate of calcium. Both alabaster and anhydrite

are used as ornamental stones. Alabaster, though softer, resembles marble in general appearance. When free from foreign substances, it assumes a finely grained structure, is or a pure white or delicately tinted colour, and is beautifully translucent. Of this class is the celebrated alabaster of Volterra in Tuscany. But it is often elegantly veined, striped, or spotted. Great numbers of beautiful statuettes, and ornaments of different kinds, are made of this material in Italy. It is found of good quality in Derbyshire, where it is also worked up into ornaments. Alabaster is slightly soluble in water, so that it is unsuitable for external work; but it does well for internal panelling or other decoration, the only drawback being the difficulty of finding it in large pieces.

Oriental Alabaster is a stalactitic carbonate of calcium (carbonate of lime), a mineral substance different from and harder than ordinary alabaster. It is really a variety of marble, and is found in Egypt, where it was worked in ancient times for urns, jars, and the like. The same kind of rock, which is sometimes extremely beautiful, is found in other parts of the world.

The name alabaster is said to be derived from the name of a town in Egypt where this kind of stone was abundant, and was manufactured into pots for perfumes. Such pots were called *alabastra*, even when made of other materials.

Alacoque, MARGUERITE MARIE, a French nun (1647-90), the founder of the devotion of the Sacred Heart (q.v.).

Ala Dagh ('beautiful mountain'), a range in the great tableland of Erzerum, in Armenia, to the north of the Lake of Van. It attains an elevation of about 11,000 feet. On its northern slope rises the Murad, the eastern head-stream of the Euphrates.

Alagoas, a maritime state of Brazil, bounded on the N. and W. by Pernambuco. The country is mountainous in the NW., and low, marshy, and unhealthy on the coast. The chief productions are the sugar-cane, cotton-plant, manioc or cassava, ipecacuanha, maize, rice, &c., and also timber and dye-woods. Pop. (1920) 990,000. The town of Alagoas, once the capital, has now only some 4000 inhabitants. The present capital is the port of Maceio; pop. about 68,000.

Alais, a town of the French department of Gard, situated in a fertile plain, at the base of the Cevennes Mountains, 31 miles NW of Nîmes by rail. It embraced the Protestant cause in the religious wars of France; and Louis XIII. and Cardinal Richelieu besieged and took it in 1629. Alais owes its prosperity chiefly to the mineral wealth of the surrounding district, which produces coal, iron, lead, zinc, and asphalt; there are large iron-foundries in the town and neighbourhood. There are also manufactures of silk and ribbons. Dumas the chemist was a native. Pop. 36,500.

Alajuela, a city of Costa Rica, Central America, 23 miles WNW. of Cartago, and a little on the western side of the watershed between the Atlantic and the Pacific. It is connected with Cartago by rail. Pop. 12,000.

Alamanni, LUIGI, Italian poet, was born at Florence in 1495, and having engaged in a conspiracy against Cardinal Giuliano, his patron, fled first to Venice, and then, on the accession of the cardinal to the papal chair, to France. In 1527 he returned to Florence. Finally, he settled in France, and was employed as a diplomatist by Francis I. and Henry II. He died at Amboise in 1556. His works (2 vols. Florence, 1869) include didactic, epic, and minor poems, much admired in their day. He influenced Wyatt.

Alameda, a town on the east side of the Bay of San Francisco, 9 miles ESE. of the city, practically a 'residential' suburb; pop. 29,000.

Alamos, Los, a mining-town of Mexico, in the southern part of the state of Sonora, 45 miles E. of the Gulf of California; pop. 10,000.

Åland Islands, some 300 small islands and rocks in the Gulf of Bothnia, opposite Åbo, the largest (Åland, 18 miles long) being about 25 miles from the Swedish coast. Eighty are inhabited. The people are Swedes, skilful sailors and fishermen. Pop. about 19,000, two-thirds in Åland. The islands belonged to Sweden, but were taken possession of by Russia in 1809. The Emperor Nicholas constructed strong fortifications at Bomarsund, on the east side of Åland, which in August 1854 were destroyed by an Anglo-French force. New forts were destroyed after the Great War, when the islands were assigned to Finland by the League of Nations, though a referendum declared for Sweden.

Alans, a nomad race, of warlike equestrian habits, belonging to the great nation of the Sarmatians. First heard of in 65 B.C., they gradually spread northwards from the Caucasus to the Don and the Volga. In 375 they were conquered and scattered by the Huns; and many of them, in 411, with the Suevi and Vandals, invaded the Spanish peninsula, and settled in Portugal, whence in 429 they were ousted by the West Goths, and passed over to Africa.

Alapulai. See AULAPOLAI.

Alarcon, PEDRO ANTONIO DE (1833-91), Spanish author and politician, was born at Guadix, and was intended for the church, but early devoted himself to journalism. He served as a volunteer in the Morocco campaign (1859), entered the Cortes as Liberal deputy for his native town, and worked for the restoration of the constitutional monarchy in the person of Alfonso XII., who made him a councillor.

Alarcon y Mendoza, JUAN RUIZ DE, one of the most eminent of Spanish dramatists, born at the town of Tasco in Mexico, about the end of the 16th century. Little is known of his early life, but in 1622 we find him at Madrid, where he was appointed to the office of *relator* (reporter) of the royal council of the Indies. His first volume of *Comedias* appeared at Madrid in 1628; his second, at Barcelona, in 1634. Throughout his lifetime, and until his death, which took place in 1639, he was assailed in venomous lampoons by contemporary poets and dramatists. For his haughty scorn of his rivals and the public, the poet was rewarded by being neglected for generations, save by plagiarists, who found his forgotten works a safe and easy prey. He is now admitted to hold a place as a dramatist next after Calderon and Lope de Vega. His plots are ingenious, but natural; his style, chaste, but vigorous; and his works are marked throughout by rare elevation of feeling. He excelled in the heroic drama, the best specimens of his kind being *El Tejedor de Segovia*. His mastery in delineating character is shown in his character-comedies. The best known are *La Verdad Sospechosa* (imitated by Corneille in his *Menteur*) and *Las Paredes Oyen*. Of his comedies of intrigue, the best is *Todo es ventura*. A complete edition of his comedies was published at Madrid by Hartzzenbusch (1848-52), and by Garcia Ramon (2 vols. 1884).

Alaric I. (*Al-ric*, 'all rich') belonged to one of the noblest families of the Visigoths. He makes his first appearance in history in 394 A.D., as leader of the Gothic auxiliaries of Theodosius in his war with Eugenius; but after the death of the former, he took advantage of the dissensions and weakness that prevailed in the Roman empire to invade

Thrace, Macedon, Thessaly, and Illyria, devastating the country (395). Rufinus, the minister of Arcadius, appears to have sacrificed Greece in order to rescue the capital, and Athens was obliged to secure its own safety by ransom. Alaric proceeded to plunder and devastate the Peloponnesus, but was interrupted by the landing of Stilicho in Elis with the troops of the western empire. Stilicho endeavoured to hem in the Goths on the Peneus; but Alaric broke through his lines, and escaped with his prisoners and booty to Illyria, of which he was appointed governor by the Emperor Arcadius, who hoped thus to make him a peaceful subject instead of a lawless enemy (399). The eastern emperor was also rendered jealous by the interference of the western empire in his affairs. In 402 Alaric invaded Upper Italy, and Honorius, the emperor of the West, fled from Rome to the more strongly fortified Ravenna. On the way to Gaul, Alaric was met and defeated by Stilicho at Pollentia on the Tanarus; but it was not till the following autumn that the result of the battle of Verona forced him to retire into Illyria. Through the mediation of Stilicho, Alaric concluded a treaty with Honorius, according to which he was to advance into Epirus, and thence attack Arcadius in conjunction with the troops of Stilicho. The projected expedition did not take place, yet Alaric demanded indemnification for having undertaken it; and Honorius, by the advice of Stilicho, promised him 4000 pounds of gold. When, after the death of Stilicho (q.v.), Honorius failed to fulfil his promise, Alaric advanced with an army, and invested Rome, which he refused to leave till he had obtained the promise of 5000 pounds of gold and 30,000 of silver. But neither did this negotiation produce any satisfactory result, and Alaric again besieged Rome (409). He took Ostia, and so stopped the food supplies of Rome. Famine soon compelled submission; and the senate allowed Alaric to appoint Attalus, the prefect of the city, emperor instead of Honorius. But Attalus displayed so little discretion, that Alaric obliged him publicly to abdicate. The renewed negotiations with Honorius proved no less fruitless than the former, and Alaric was so irritated at a perfidious attempt to fall upon him by surprise at Ravenna, that for the third time he advanced on Rome. His victorious army entered the city on August 24, 410, and continued to pillage it for six days, Alaric strictly forbidding his soldiers to dishonour women or destroy religious buildings. The prohibition served little to mitigate the horrors of the dreadful week. When Alaric quitted Rome, it was only to prosecute the conquest of Sicily; the occurrence of a storm, however, which his ill-constructed vessels were not able to resist, obliged him to abandon the project for the time; and his death, which took place at Cosenza, in Calabria, soon after (410), prevented his resuming it. He was but 34 years of age. Legend tells that, to hide his remains from the Romans, they were deposited in the bed of the river Busento, and the captives who had been employed in the work were put to death. Rome and all Italy celebrated the death of Alaric with public festivities; and the world enjoyed a momentary repose. But Alaric himself was much less barbarous than his followers. He admired those monuments of civilisation with which the Eternal City abounded, and sought to preserve them; he checked the excesses of his fierce soldiery, and at times gave indications that the lessons of Christianity which he had learned from the Arian missionaries had not been altogether forgotten. Yet through him, the Goths learned the way to Rome.

Alaric II., eighth king of the Visigoths, succeeded his father in 484 A.D. His dominions comprised all Gaul beyond the Loire and Rhine,

and most of Spain. He was an Arian, and this gave the orthodox Clovis, king of France, an excuse for making war on the heretic. Alaric's forces were completely routed near Poitiers, and he himself was overtaken and slain by the hand of Clovis (507). See GOTHs, CODE.

Alarm, or **ALARUM** (from Ital. *all' arme*, 'to arms'), is originally a call to arms, or the signal for this purpose, as the loud and hurried peal of an alarm-bell. Now it is commonly used of an instrument or apparatus for awakening sleepers—generally attached to a clock. It usually consists of a hammer and bell, with an escapement that lets it free at any hour arranged, when a spring or weight brings the hammer to bear on the bell.

Alarodian, a name used by Sayce for the group of languages of which Georgian is the type. See GEORGIA, CAUCASUS.

Ala-shehr (i.e. 'the exalted city,' ancient *Philadelphía*), a city of Asia Minor, 75 miles E. of Smyrna, at the NE. base of Mount Tmolus. It was founded by Attalus Philadelphus, king of Pergamos, about 200 B.C., and is famous as the seat of one of the Seven Churches of Asia. It is still a place of considerable importance, is the seat of a Greek archbishopric, and carries on a thriving trade in corn, tobacco, and cotton fabrics, chiefly with Smyrna, to which it is now joined by a railway. There are many interesting antiquities. Pop. about 15,000, including 3000 Greeks.

Alaska, a territory of the United States, occupying the NW. portion of the North American continent, together with all the islands near its coast, and the Aleutian Archipelago except Behring and Copper Islands. It is bounded on the N. by the Arctic Ocean, on the E. by the Canadian Territory of Yukon and by British Columbia, on the SW. by the Pacific Ocean, and W. by Behring Sea and the Arctic Ocean. Its land area is estimated at 590,900 sq. m. The northern portion consists essentially of a vast expanse of tundra, broken here and there by mountain-spurs (including the highest peak in N. America, Mount McKinley, 20,464 feet), and varied by countless lakes, water-courses, and sphagnum swamps. About one-third of this region lies within the arctic circle. Its winter climate is terribly severe, and the short summers are rendered almost unendurable by clouds of gnats. It is traversed by the great river Yukon, about 2000 miles long, which is said to discharge more water into the sea than the Mississippi, and by its main tributary the Tananah, the Kuskokwim, and other large streams. Its population is Innuít or Eskimo in the north and on the coast, but Athabaskan or Tinnéh (Red Indian) elsewhere. The fisheries and the fur-trade afford subsistence to the scanty population. Commerce is much obstructed by the shallows which border the eastern shores of Behring Sea.

A second section comprises the Aleutian Islands (q. v.), and a great part of the peninsula of Alaska. This division is mountainous, and actively volcanic; it is very thinly peopled by the Aleuts. The Pribylov Islands, in Behring Sea, are the main fur-sealing centre (see SEAL). The sea-otter (see OTTER) has been almost exterminated.

South-eastern Alaska, a narrow strip of land, along with the Alexander Archipelago, lies between Canada and the sea. The boundary as defined in the Russo-British treaty of 1825 is given as 'ten marine leagues from the ocean.' The exact meaning of this definition was disputed between Canada and the United States, especially after the discovery of gold in the Yukon valley gave more importance to the possession of a Canadian harbour on the coast. A joint commission in 1903 practically gave effect to the United States' contention, and fixed the boundary-line from the head of Port-

land Channel through Mount Whipple and Kate's Needle, round the head of Lynn Channel to Mount St Elias. This shuts out Canada entirely from the coast, but for a joint right to Portland Channel and the possession of two islands (Wales and Pearse) at its mouth.

The native animals of Alaska include the caribou or reindeer (120,000 head), the moose, the Rocky Mountain sheep, bears, wolves, foxes, sea-otter, and fur-seal. The most valuable food fishes are the salmon, halibut, and cod. The salmon-fisheries are of especial importance; the export of canned, cured, and fresh salmon to the U.S.A. exceeds £3,000,000 per annum. Off the coast are large kelp-beds. Hardy vegetables and cereals are grown, the grass crop is of some value, and the forests of south-eastern Alaska contain dense growths of coniferous timber, as yet practically untouched. But the great source of Alaskan wealth lies in its minerals, which, aside from gold, have been little exploited. Gold has long been mined at Juneau, and since 1885 many placer-deposits have been worked—the most valuable at Cape Nome and Cape York, in western Alaska, which have yielded largely since 1899. Other minerals include iron ore and copper and coal beds (both bituminous and anthracite) of extraordinary richness, as also platinum.

Alaska, formerly called Russian America, was first visited by the Russians under Vitus Behring in 1741; in 1799 the country passed under the control of the Russian America Company; in 1867 it was purchased from Russia by the United States for \$7,200,000 in gold. Alaska was strictly a district, directly under the control of Congress, like the District of Columbia, until by Act of Congress, approved August 1912, it was made a territory with legislature of its own. White population in 1890, 4500; in 1910 the permanent population was 64,356, besides 7000 who came annually for a few months to work at mines, canneries, and railways; (1920) 55,036. The towns are all small, and most of them are on the coast. They include Juneau, capital since 1906 (pop. 3000); Sitka, the former capital (1000); Ketchikan (3000); Anchorage (2000); Skagway; Nome, on the west coast; and Fairbanks.

See BEHRING STRAIT; books by Woolman (1890), Wardman (1885), Elliott (1886), Seton Karr (1887), Sheldon Jackson, Seidmore (1893), Greely (1909), Stuck (1914, 1919).

Ala-tau ('mottled'), a name given to a range of lofty mountains forming the boundary between Turkestan and Mongolia, and the northern limit of the great tableland of Central Asia. It is made up of five sierra-like sub-ranges, the Zungarian, the Trans-Ili, the Kungei, and the Terskei Ala-tau, the fifth, running west, having been renamed by the Russians the Alexander Range. These are all grouped round Lake Issik-Kul (elevation, 5300 feet) as a central point. The mountains, which are principally of granite formation, range generally in elevation from 10,000 to 15,000 feet, and the loftiest peak, Khan Tengri, is 24,000 feet above the sea.

Alaternus. See BUCKTHORN.

Alatyr, a town in the Russian province of Simbirsk, on the Sura, 103 miles NW. of Simbiisk; pop. 11,000.

Alausí, a town of Ecuador, in the province of Chimborazo, 70 miles E. of Guayaquil, at an elevation of 7980 feet above the sea; pop. 6000.

Álava, the southern and largest, but most sparsely populated, of the three Basque provinces of Spain. The country forms a series of terraces of the Cantabrian Range, trending south to the river Ebro. The mountains are scattered through the whole province, and yield various minerals, stone, and timber in abundance. The climate is mild and

salubrious. Area, 1200 sq. m. The inhabitants (97,000), many of them Basques (q.v.), are engaged in agriculture. The soil is generally fertile, and along the Ebro fruits and wine are produced, while the other valleys yield good crops of maize and hemp. Cattle and sheep are grazed on the uplands; and a number of iron, asphalt, and salt mines are worked. The capital is Vitoria.

Álava, DON MIGUEL RICARDO DE, a Spanish general, born of a noble family at Vitoria in 1771. At first a supporter of Joseph Bonaparte, he deserted to the winning side in 1811, and attracted the favourable notice of Wellington, who made him a general of brigade. Soon after the restoration of Ferdinand VII., Álava was appointed ambassador to the Hague. He returned to Spain in 1820 after the revolution, was sent as a deputy to the Cortes, and became a leader in the party of the *Exaltados*, voting for the suspension of the royal authority. The re-establishment of absolute monarchy in the Peninsula drove him a political refugee to Brussels and England, till, at Ferdinand's death (1833), he was recalled by the regent Maria Cristina, and sent on missions to London and Paris. He refused to swear to the revived constitution of 1812, declaring that he was tired of constantly taking new oaths; accordingly in 1837 he gave in his resignation, and retired to France, where he died at Bareges in 1843.

Alb (Lat. *albus*, 'white'), the long white linen vestment worn by priests and acolytes

Alb.

in the Roman Catholic and also the Anglican Church. It differed from the more modern Surplice (q.v.) in having narrower sleeves, and fitting more closely to the body, being bound about the waist by a cincture. At the foot and wrists were embroidered ornaments called *apparels*. In the ancient church, the newly baptised wore it for eight days, and hence catechumens were called *albat*; and the Sunday after Easter, on which they usually received baptism, came to be called Dominica in Albis. See WHITSUNTIDE.

Alba (ancient *Alba Pompeia*), a very ancient city of North Italy, in the province of Cuneo, on the right bank of the Tanaro, 41 miles SW. of Alessandria by rail. Alba is an episcopal seat; the cathedral was founded in 1486. Pop. 15,000.

Albacete, capital of a Spanish province, 140 miles SE. of Madrid by rail, stands in a fertile but treeless plain. It has great cattle-fairs, and was formerly noted for the manufacture of knives and other steel goods. Pop. 25,000.—The province of Albacete is partly formed from the former kingdom of Murcia, and partly from New Castile. It is generally hilly, and in some parts mountainous, some of its mountains attaining an altitude of 5000 feet; but it contains also rich plains and fertile valleys. The area of the province, which has much mineral wealth, is 5800 sq. m.; pop. 260,000.

Albacore. See TUNNY.

Alba Longa, the most ancient city of Latium, situated on the rocky ridge that runs along the eastern shore of the Alban Lake, between it and the Alban Mount. According to legendary history, it was built by Ascanius, the son of Æneas, about 300 years before the foundation of Rome,

which is represented as a colony of Alba Longa. Notwithstanding this, the Romans, under Tullius Hostilius, destroyed the city, and removed the inhabitants to Rome. It seems certain that Alba Longa was an important city long before the existence of Rome, and the head of a confederation of Latin towns, and that when it was destroyed many of its inhabitants settled at Rome. Traces of its walls may yet be seen. See ALBANO.

Alban, St, the first martyr of Britain. See ST ALBANS.

Albani, FRANCESCO, a painter of the Bolognese school, of the time of the Caracci, was born at Bologna in 1578, and died there in 1660. He studied, along with Guido Reni, first under Calvaert, and afterwards under Ludovico Caracci. He painted about forty-five altar-pieces; but his bent inclined him more to the representation of idyllic scenes from ancient mythology or from contemporary pastoral poetry. He had by his second wife a family of twelve children of extraordinary beauty, in whom he found exquisite models for his Venuses, Galateas, and angels' heads. His representation of the Four Seasons was often imitated.

Albani, MADAME (Emma Lajeunesse), singer, was born 1st November 1852 at Chambly, in Canada, and, trained in music by her father, at the age of fourteen was soprano in a Catholic church at Albany—whence her professional name of 'Albani.' She studied afterwards at Paris and Milan, and in 1870 sang in opera at Messina with a success that attended her everywhere in oratorio as in opera. In 1878 she married Ernest Gye, impresario. See her autobiographical *Forty Years of Song* (1911).

Albania, the Byzantine name for the country called by its inhabitants Shkypëria or Shkypeni, is one of the latest of the principalities or states to be carved out of the wreck of the Ottoman empire, though its people are the oldest in the Balkans and among the most ancient in Europe. The new state, whose frontiers were approximately settled by the Conference of London in 1913, possesses a fairly valuable strip of sea-coast on the eastern shores of the Adriatic, stretching from the mouth of the Boyana in the north to Paganía, opposite Corfu, in the south; but the interior is rocky and generally worthless.

Two-thirds of the way up the Boyana the frontier strikes north across Lake Scodra to the Hoti and Castrati inlets on the east, leaving the Tarabosh to Albania, but on the other side of the lake giving the Albanian tribes of Hoti and Gruda to Montenegro. For some miles the old frontier is followed, and then the line strikes south by east to include the Moslem-Albanian towns of Gussigne and Plava in Montenegro. The frontier then goes south-east along the watershed of the White Drin, leaving Ipek, Jacova, and Priserend, all predominantly Albanian towns, to Montenegro and Serbia, and turns almost due south to Lake Ochrida, including the Liuma district in Albania, but depriving it of Dibra and the Reka valley, from which the Shkypëtar were exterminated by the Serbians in the war of 1912. From Lake Ochrida the frontier is even less carefully drawn, but it includes Biklishta in the new state, and then runs south-west in a zig-zagging line to Paganía, on the coast opposite Corfu, thus depriving Albania of Yanina, the town and country ruled, in defiance of the sultan, by the famous Albanian, Ali Pasha of Tepelen.

The new state thus delimited contains 11,317 sq. m., and a population of about a million, or about half the area and rather more than half the population it justly should contain; and even these remnants of a rocky patrimony are coveted by Greeks in the south and by Slavs in the north.

The principal towns are Scodra (usually called Scutari in Europe), the metropolis of North Albania, with a mixed Moslem and Roman Catholic population of about 35,000 inhabitants—it is a purely Albanian city, and is the seat of the ancient Roman Catholic archbishopric of Dioeclea; Durazzo (3000), the capital of the short-lived reign of the impret, the future commercial port of the country; Tirana, the emerald city (12,000), the centre of influence wielded by the late Essad Pasha and the Toptani family; Elbassan (8000), an important Moslem town; Berat (15,000), the white city; and Avlona (5000), the seaport which gives Albania its strategical importance and is the centre of Italian influence and propaganda.

The principal rivers are the Boyana, the outlet for Lake Scodra; the Drin, the most important river of Albania but an unregulated mountain torrent; the Mati, the Ishmi, the Arzen; the Skumbi, which separates North and South Albania; the Semeni with its two branches, the Devoli and the Osum; and the Voyussa, the second river in size, into which flow the Zrinos and the Susitza. All these streams wind through the mountains of the interior to the marshes of the sea-coast, and are of little or no use as means of navigation. Of the Albanian lakes, Yanina, Presba, and Vintrok are completely lost; of Scodra only the south-east corner is left, and of Ochrida only the south-west. The lagoons of Kravasta, Soli, Valona, and Butrinto, and the rest along the coast, are nothing but sources of fever, and need draining first of all.

Generally speaking, the country is a mass of mountains sloping down to the sea. In the north the mountains are known as the Albanian Alps, and are said to reach about 9000 feet south of Gussigne, though the imposing-looking summits above Scodra, Mounts Zucali and Maranai, only attain to 5500 feet and 5000 feet respectively. The Shah Dag is now lost to Albania, and with it some of the highest peaks, for the branch running south on the left bank of the Drin above Dibra seldom rises above 3000 feet. In Central Albania Mount Tomor is about 7000 feet high, and farther south Mount Cica, the highest peak of the Acroceraunian Mountains, rises to something like 6000 feet.

The Albanians—or Shkypetars, as they are properly called—are the remnants of a race which inhabited the Balkans at the dawn of history, and are of pure Aryan stock. They are a blonde race, far whiter than the Serbs, the Bulgars, or the Turks, all of whom came out of Asia centuries afterwards. They represent the Thrako-Illyrian tribes who held the main part of the Balkans when the Hellenes of classic times occupied the Peloponnesus and the peninsula above it. From very early times the division into Ghegs in the north, or Illyria, and Tosks in the south, or Epirus, seems to have prevailed, and the two parts speak slightly different dialects of their ancient tongue, which in the north has been corrupted by Slav words, and in the south by Greek. The name Shkypetar is derived by some from *shkip*, a rock, and thus signifies Hillmen; while others derive it from *shkyup*, an eagle, signifying Sons of the Eagle. This latter seems more in accordance with ancient tradition, as the Shkypetars since the days of Pyrrhus have always boasted themselves to be the Sons of the Mountain Eagle. Moreover, they have adopted an eagle as the emblem of the new state.

The Shkypetars were very early converted to Christianity—indeed, St Paul himself is said to have founded the Church at Durazzo; but when the schism occurred North Albania adhered to the Pope of Rome, and South Albania to the Byzantine Patriarch. On the coming of the Turks large numbers, especially in Middle Albania, embraced the Moslem faith, and as a rule the chiefs, except

the Bib Dodas of Mirditia, adopted the religion of the new conquerors for business reasons.

The North Albanians are divided into many tribes. On the Montenegrin frontier are the Malisors, the chief tribes of whom are Hoti and Gruda, now recklessly assigned to Montenegro, and Castrati, Clementi, and Skrelli. Towards Pisrend are Pulati, Shoshi, and Shalla and Liuma, to the south of whom are the mountains of the great Roman Catholic Mirdite tribe. Round Scodra and in the Zadrima are a number of very small tribes or families, but in Middle Albania and South Albania the tribes are much fewer in number, and are really comprised in the Tosks proper and the Lapidés. The towns are more numerous than in North Albania, and the Beys and Aghas exercise a feudal sway over the people, whereas in North Albania the tribal council is the central power. The southern Tosks have been erroneously or dishonestly claimed as of Greek nationality because they are of the Greek religion; but, on the other hand, a number of them emigrated in times past to Greece, and there are probably not far short of 100,000 people of Albanian descent in Greece and the islands. About the time of Scanderbeg several Albanian colonies were founded in south Italy and Sicily, and there are now some 200,000 settlers of Albanian blood in Italy. Several statesmen have been contributed to the Italian kingdom by these colonists, and it must not be forgotten that Mehemet Ali Pasha, who founded the dynasty of the Khedives in Egypt, was an Albanian. In the Ottoman empire many grand viziers and famous pashas were purebred Shkypetars. Altogether, inside and outside the new state of Albania there are over 2,000,000 Shkypetars, of whom 1,000,000 are Moslems, about 600,000 Orthodox, and 400,000 Latins.

Albanian is a very old Indo-European tongue, and is the descendant of the Thrako-Illyrian language of classical times. But it is a very poor language, and is eked out by words derived from Latin and others borrowed from Turkish, Greek, and Slav. It has only recently been given an alphabet, or rather three, for the Latin alphabet has been introduced by the Roman Catholic priests in the north, the Greek alphabet by the orthodox clergy in the south, and latterly the Turkish script had been enforced in the Turkish schools. None of these forms of writing completely suits Albanian, and various modifications have had to be made in the letters to express the Albanian pronunciation. Albanian cannot be said to possess any literature, only legends and folk-songs; and if any Albanians write, they use Italian or, in some cases, French.

Formerly the costumes of the Albanians were exceedingly picturesque, and every tribe had its distinguishing dress, but now the tendency is to adopt the commonplace but commodious clothing of Europe. Generally speaking the Moslem townsmen wear the fustanelle, or full white linen petticoat, and the women of the towns Turkish dress. In the mountains the women go unveiled, and wear skirts of red cloth embroidered with black, and the men wear a tight-fitting suit of white felt ornamented with black embroidery. But the fustanelle is being discarded as too inconvenient, and in the coast-towns the slop suits of Trieste and Italy are ousting the mediæval costumes.

The natural allies of the Shkypetars are the Greeks, the nearest non-Slav race; and from the earliest times the two countries seem to have been allied, for Clinicus, king of Illyria, is said to have sent seventy-two ships with the Greeks to the siege of Troy. At the beginning of the 6th century Illyria was overrun by the Kelts, and this was the first of the invasions of the Balkans of which we have any record. About 360 B.C. Bardyles, king of Illyria, conquered Epirus and invaded Mace-

donia, but was defeated by Philip of Macedon, father of Alexander the Great, and his country annexed as far north as Durazzo. The Shkypetars formed part of the army which invaded Persia and India under Alexander the Great; and after his death the country, with Scodia as its capital, regained its independence, conquered Epirus and Corfu, and fought against the Ætolian League, about 250 B.C., under King Agrom. Teuta, the widow of Agrom, came into collision with Rome, with the result that the land was placed under the protection of the Republic. During the Macedonian wars the Shkypetars wavered between Macedonia and Rome; but Gentius, the last king, not only allied himself with Perseus, but turned pirate, so in 168 B.C. the prætor Amincius captured Scodra and took Gentius and his sons prisoners. Illyria and Epirus were made Roman provinces, and the walls of all the cities of Epirus were destroyed. Only the towns along the coast were allowed to exist; but though the Via Egnatia was driven through the country, the mountaineers were left semi-independent. During the wars between Cæsar and Pompey, and Antony and Octavius, Durazzo and Valona were ports of the highest strategical value, but under the Empire both Illyria and Epirus were utterly neglected.

In 395 A.D. the lands of the Shkypetar were allotted to the Eastern empire, and the prefects of Byzantium ruled in the lowlands, while the tribes of the interior were as independent as they were in after-times under the Turks. At the opening of the 5th century Alaric with his Goths, and later on the Huns and the Ostrogoths, ravaged the country; but the Slavs, who invaded the empire in numbers at the end of the 6th century, were the first barbarians who came to settle. They scattered the semi-civilised Thrako-Illyrian tribes before them by their locust-like invasion, and drove them into the mountains of the west; and the Albanians, or Shkypetars, are now the remnant left of the old race, between whom and the invading Slav there is undying hatred. The Bulgars followed, and the history of Albania until the coming of the Turks may be summarised as consisting in the occupation of the coasts and plains by the Byzantines, Serbs, and Bulgars in turn, while the native Shkypetars maintained a wild independence in their mountains. Simeon and Shishman the Bulgars, the Emperor Basil Bulgaroktonos, Stefan and Dushan the Serbs, and again the emperors of Byzantium, in turn held sway in Shkypetia until the coming of the Turks, when native princes and Venice shared the overlordship at various times. In 1467, when Scanderbeg the Shkypetar hero died, and the land fell under the Ottoman empire, the pashas ruled like the Byzantine prefects, but the law of the tribes prevailed in the mountains. In the 18th century the North Albanians were ruled by native pashas, and the South Albanians at the beginning of the 19th century by Ali Pasha of Yanina, the Mirdites and the Albanians of the centre also having their native rulers. Government from Constantinople direct was not introduced until after the Crimean war, and in 1878 the Albanian League was founded, which was directed against all enemies of the Shkypetar nationality, including the Turks, but was unable to prevent the cession of Dulcigno to Montenegro.

When the 'Constitution' was promulgated in 1908 the Shkypetars thought that it meant independence, but they soon found that the Young Turks meant to destroy their nationality, and in 1910 the tribes rose against the government. During the Balkan wars the Shkypetars as a rule took a passive part, as they could not join the Allies and would not fight for the Young Turks; but Scodra was captured by the Montenegrins,

Yanina by the Greeks, and Durazzo by the Serbians, who also massacred the villagers wholesale in North Albania. The new state was outlined at the Conference of London in 1913, and on 7th March 1914 Prince William of Wied, the newly chosen king, or nupret, of Albania, landed at Durazzo with his wife and staff. He was singularly ill-fitted to rule over the free Shkypetars, for, though in appearance he was the ideal warrior, in mind he was a German bureaucrat. After nearly six months of stormy life at Durazzo, the prince finally left his kingdom on 3d September 1914, and returned to Germany to fight for the Kaiser. Albania relapsed into the rule of local and tribal chieftains, and on 30th October Italy occupied the rocky islet of Saseno, off Avlona, and Greece a day or two later annexed Epirus.

Until the coming of the Austrians, Mirditia remained under its native prince, Pienck Bib Doda (murdered in 1919); Durazzo and Central Albania under the rule of Essad Pasha (murdered in Paris, 13th June 1920); and Valona under the International Commission of Control. South Albania was occupied by the Greeks, and Scutari governed by a mixed commission of Moslem and Roman Catholic townsmen. When the Austrians swept through Serbia and Albania they advanced almost to Avlona, the country round which was occupied by the Italians; but when the Allies broke Bulgaria in 1918, they advanced through Albania in their turn. The people strongly resented the occupation by the Italians, and fought against them round Avlona in 1919. In 1920 the Italians decided to retire from the country, and the Albanians, after their experiences in the Great War, made a truce among themselves, and formed a government at Tirana which was representative of the whole of Albania. A constitution, adopted in 1920 and modified in 1922 and 1925, makes Albania a republic with a president and a two-chamber assembly, but whether this arrangement will be lasting remains to be seen. Some form of central government, with large powers left to the local authorities, seems the best solution, and in course of time some sort of an alliance with Greece, when that country settles down and can remember to treat the Albanians on equal terms. Italy, Greece, and Albania will have to come to an understanding, for, with the exception of Rumania, they are the only non-Slav races in the Near East, and must form an alliance if they are to continue to exist.

Consult the works of Von Hahn, Jaray, and Galanti; *High Albania* and *The Struggle for Scutari*, by M. E. Durham; and *Albania, the Foundling State of Europe*, by Wadham Peacock.

Albano, 18 miles SSE. of Rome, on the declivity of the lava-walls which encompass Lake Albano, and opposite the site of Alba Longa (q.v.), is the seat of a bishop, and has many remains of ancient buildings. A fine wine is made. Pop. 9000.

The **ALBAN LAKE**, or Lago di Castello, is formed in the basin of an extinct volcano, and has a circumference of 6 miles, with a depth of 530 feet. Its surface is 961 feet above the sea-level. While the Romans were at war with Veii (390 B.C.), this lake rose to an extraordinary height in the heat of summer, and diviners declared that the conquest of Veii depended upon letting off the waters. Thereupon the Romans opened a tunnel through the lava-wall. The tunnel, which still fulfils its office, is a mile long, 7 feet high, and 4 feet wide. On the eastern bank of the lake rises Monte Cavo (Mons Albanus), 3000 feet high.

Albany, or **ALBAN**, an ancient name for the Highlands of Scotland. Etymologically connected with the Gaelic *alp*, 'a high hill,' and the Lat. *albus*, 'white,' it is the Gaelic form of the Cymric *Albion*, a term applied to the entire British Island

in a treatise on the World, once ascribed to Aristotle. It may, indeed, be pretty safely assumed that Albion or Albany was the original name of Britain among its Celtic population; and we know that from the close of the 9th till the beginning of the 11th century Pictavia, or the kingdom of Scone, was known as the kingdom of Alban. In 1398 the title of Duke of Albany was conferred on the brother of King Robert III., then regent. Forfeited by his son, it was conferred on Alexander, second son of James II., in the person of whose son, John, it became extinct in 1536. It was conferred in succession on Darnley, on Charles I. in infancy, on James II. in infancy, and (as a British title) on Frederick, second son of George III. Prince Charles Stuart assumed the appellation of Count of Albany as an incognito title, and gave the title of Duchess of Albany to his legitimated daughter. The title, restored in 1881, was conferred upon Prince Leopold (1853-84), whose son (Duke of Saxe-Coburg) was deprived of it by act of parliament (1917).

Albany, a city of the United States, capital of the state of New York, seat of justice of Albany county, and a most important railway and commercial centre, stands on the west bank of Hudson River, 145 miles N. of New York city. The river is an important channel of commerce, which is further facilitated by the Erie and Champlain Canals. Six important railway lines centre in this city. The older streets are irregularly laid out. The city has a copious water-supply, and excellent drainage and sewerage systems; inter-urban electric railways connect it with adjoining cities. Albany has a state library and education department, a fine city-hall, a high-school, one large public park and nearly twenty smaller ones, besides boulevards and avenues; a celebrated county-prison; Roman Catholic and Episcopalian cathedrals, and many other handsome churches; fine banks and clubs, several 'academies' and private schools, a noted state normal school, schools of law, medicine, and pharmacy (of Union University, Shenectady); an astronomical observatory, various hospitals and infirmaries, a large United States government building, and a very costly and splendid state capitol, considered the finest building of its class in the whole republic. Three bridges and several ferries cross the river to the suburban town of Rensselaer (formerly Greenbush). Albany has a large trade in timber, grain, and cattle. Leading articles of manufacture are farming implements, boots and shoes, bricks, wagons, clothing, flour, stoves, castings and hollow-ware, furniture, tobacco, cigars, musical instruments, and stationers' goods. The situation of Albany at the connection of so many important railways and of two great canals with tide-water makes it a great place for the handling or transfer of the bulky staples of interior production. A specialty in the trade of the city is the handling of barley. It is one of the largest seats of the manufacture of cast-iron stoves and heating apparatus; and its ales and beer had formerly a great celebrity. The hilly and irregular site of the town greatly facilitates drainage. The winter climate of Albany is severe for its latitude. The extensive cattle-markets of this city are situated at West Albany, where there are large railway-shops. Near the site of Albany the Dutch founded a block-house and fur-trading station in 1614. The Dutch villages of Beverwyck or Fort Orange (1618) and Willemstedt (1646) were the germs of the present city. The Dutch colony was ceded to Great Britain in 1664, and the town took its present name in honour of the Duke of York and Albany, afterwards James II. of England, who received a grant of the colony. In 1686 a city charter was granted to Albany, which is thus the

oldest chartered city in the United States. In 1764 the first general congress of the English colonies assembled here. The city long retained many quaint Dutch characteristics. Pop. (1800) 5349; (1830) 24,209; (1900) 94,151; (1920) 113,344.

Albany, in Western Australia, on one of the most sheltered inlets of King George's Sound, was first occupied in 1826 to anticipate a supposed intention of the French government to seize that part of Western Australia. The harbour is good but small. For many years it was a port of call for the mail-boats to and from England, but has now been superseded by Fremantle (q.v.); the mail-boats to and from South Africa still use it. It is connected by rail with Perth, 352 miles away. The climate of the district is exceptionally fine, and the scenery pleasing, so that it has become a health and pleasure resort. Pop. 4000

Albany, LOUISA, COUNTESS OF, was born in 1752, the daughter of Prince Gustav Adolf of Stolberg, who fell in the battle of Luthen (1757). A bright, merry girl of nineteen, in 1772 she was married to Prince Charles Edward, no longer 'bonny,' and no longer 'young,' but a selfish worn-out sot. No children came of the marriage; and in 1780, to escape from ill-usage, the countess sought refuge in a nunnery. Three years later she obtained a separation; both before and after her husband's death (1788) she lived with the poet Alfieri (q.v.), and on his death (1803), with a French painter, Fabie; but it was by the poet's side, twenty-one years later, she was buried (1824) in the church of Santa Croce at Florence. See Reumont's *Grafyn von Albany* (2 vols. Berl. 1860), and Vernon Lee's *Countess of Albany* (1884).

Albany, THE, bachelor quarters let out in chambers (to Canning, Byron, and Macaulay in their time), are on the north side of Piccadilly, a little beyond Burlington House.

Albatross, or ALBATROS, a name applied to the larger Diomedidae, a family closely related to the petrels, but not even distantly to the gulls. An albatross may be at once distinguished from a large gull by the curious tubular, not slit-like, nostrils. The largest and best-known species is the wandering albatross (*Diomedea exulans*) of the southern ocean, which may measure 11 feet 4

Albatross.

inches from tip to tip of its outspread wings. The plumage is mostly white, mottled above by wavy bars, and with brownish-black quill feathers on the wing. The strong flight is particularly interesting because of its fine exhibition of 'sailing'—that is, of moving for a long time without any perceptible stroke of the wings, either with or against the wind, close to the water or at a considerable height. In this way it wheels in great circles round

the ship. The albatross is very voracious, feeding on fish, cuttlefish, jellyfish, and the like, and it is said to gorge itself sometimes so heavily with dead whale that it is unable to rise from the water. The nesting-places are solitary islands with high plateaux, and large numbers nest together. A single white egg is laid in a slight hollow on the top of a mound of mud and vegetable matter; the development is slow, and the young birds are for a long time dependent on their parents. It is to be regretted that the colonies are sometimes ruthlessly disturbed, and that the magnificent bird, whose flesh is unpalatable, is often shot at by travellers, in spite of Coleridge's *Ancient Mariner*. Besides *D. exulans* there are about fifteen species of albatross—e.g. *D. albatrus* and *D. brachyura* of the North Pacific, and the sooty albatross (*Phœbeteria fuliginosa*) of the far South. A black-biowed albatross (*D. melanophrys*) was captured in Cambridgeshire in 1897. The sailor's name for the smaller species of albatross is 'mollymawk.' The name seems to be a modified form of Alcatraz, a Portuguese word for the bucket of a water-wheel; applied first to the pelican, then to the figate-bird, and then, modified in spelling, to the bird above described.

Albay, capital of a fertile province, constituting the south end of the Philippine island of Luzon, near the Bay of Albay. Manila hemp is shipped to Manila, and cocoa, copra, and sugar are exported. Pop. 43,000.

Albemarle, the English form of Aumale (q.v.), in Normandy, whose first earl, Odo, received from his brother-in-law, William the Conqueror, a lordship in Yorkshire. Both lordship and title reverted to the crown in the reign of Henry III.; and four times subsequently was the dukedom of Albemarle conferred on four different persons—as in 1423 on Richard Beauchamp, Earl of Warwick, and in 1660 on his *soi-disant* descendant, General Monk (q.v.). It expired with his son in 1688; and in 1696 the title of Earl of Albemarle was granted to Arnold Joost van Keppel (1669–1718), a devoted follower of William III., who in 1703 joined the forces of the Allies, fought at Ramillies, Oudenarde, and Lille, and led Marlborough's second line in 1711. Among his descendants have been William, second earl (1732–54), soldier and diplomatist; George, third earl (1724–72), who captured Havana; and George Thomas Keppel, sixth earl (1799–1891), who fought at Waterloo, served at the Cape and in India, and rose to be general in 1874. He was private secretary to Lord John Russell as premier, sat as a Whig M.P. in 1847–49, and succeeded to the title in 1851. He wrote *Fifty Years of my Life* (1876).

Albemarle Sound, a rather shallow inlet in the north coast of North Carolina, United States, running inland for 60 miles, with a breadth of from 4 to 15 miles.

Alberoni, GIULIO, cardinal and statesman, was born in 1664 at Firenzuola in Parma, the son of a poor vine-dresser; but his great abilities led to his being carried by the Duc de Vendôme, as secretary, to France and Spain. In 1713 the Duke of Parma employed him as his agent in Madrid, and here he quickly gained the favour of Philip V. of Spain. He at first made use of the influence of the Princess Orsini, then hoodwinked her into promoting the king's marriage with Elizabeth Farnese, who as queen at once demanded the banishment of the princess. Alberoni now (1714) became prime minister of Spain, and was made a cardinal by Clement XI. three years later. He did much to develop the resources of Spain and encourage industry and economy, while he remodelled the army and the fleet, and increased the

foreign commerce. To gratify the queen he suddenly invaded Sardinia, in violation of the Peace of Utrecht. This unexpected audacity made England, France, Austria, and Holland form, in 1719, the 'Quadruple Alliance.' But Alberoni, though responsible for a succession of Spanish disasters, was not dismayed. Even when the Spanish fleet in the Mediterranean was destroyed by an English one, he contemplated an extensive war by land, in which all the European powers would have been entangled. He patronised the Pretender to annoy England, and the French Protestants to annoy Louis. He sought to unite Peter of Russia and Charles XII. with him, to plunge Austria into a war with the Turks, to stir up an insurrection in Hungary, and to bring about the downfall of the regent in France. But Philip lost courage, and concluded a treaty of peace, the chief condition of which was that the cardinal should be dismissed. He was ordered to leave Spain without delay (1719), the queen herself consenting to his banishment. He fled to Italy, where, threatened with imprisonment by Pope Clement XI., he hid in a monastery at Bologna (1720). On the death of the pope in 1721, he repaired to Rome, and took part in the election of Innocent XIII., who, like his two successors, befriended the great exile, though on the demand of Spain he imprisoned him for a while. Alberoni was even proposed as candidate for the papacy, but soon retired to Piacenza, and spent his remaining years in watching over a seminary which he had founded and endowed. He died there June 1752. See *Lives* by Bersani (1862) and Bianchi (1901).

Albert, dukes of Austria and emperors of Germany. See AUSTRIA, GERMANY.

Albert (1490–1545), Archbishop of Magdeburg and Elector of Mainz, was younger son of the Elector of Brandenburg. Leo X. having granted him permission to sell indulgences, Albert appointed the Dominican Tetzel as his agent, who, by the shameless manner in which he went about his work, first roused the wrath of Luther. A friend of literature, he was not originally unfriendly to reformation; but he ultimately sided strongly against the Reformers.

Albert (1490–1568), last grand-master of the Teutonic Knights (q.v.) and first Duke of Prussia, was a younger son of the Margrave of Anspach. Elected grand-master in 1511, he embraced the Reformation, and, by Luther's advice, declared himself secular Duke of Prussia (q.v.).

Albert, PRINCE CONSORT OF ENGLAND, was born at Schloss Rosenau, near Coburg, August 26, 1819, the younger son of the Duke of Saxe-Coburg-Gotha, by his first marriage with Louisa, daughter of the Duke of Saxe-Gotha-Altenburg. After a careful domestic education, the Prince, along with his elder brother, studied at Brussels and Bonn (1836–38), where, in addition to the sciences connected with state-craft, he devoted himself with ardour to natural history, chemistry, painting, and music. He attained expertness in all knightly exercises; whilst by Baron Stockmar, his mentor, he was imbued with a real interest in European politics. Queen Victoria and he met first in 1836, and fell in love, though the marriage had long been projected by King Leopold and Baron Stockmar. It was celebrated in London on the 10th of February 1840, when Prince Albert received the title of Royal Highness, was naturalised as a subject of Great Britain, and obtained the rank of Field-marshal. The title of Consort of Her Most Gracious Majesty was conferred in 1842, that of Prince Consort in 1857. With rare prudence and tact he abstained from conspicuous intervention with state affairs; but the publication of the Queen's letters (in 1907) proved that he strongly

supported the Queen in her efforts to strengthen the influence of the crown and direct British policy in a direction hostile to Italian and other nationalist aspirations. When the Whig ministry of 1840 proposed for him the income of £50,000, the Toies, in conjunction with the Radicals, limited the sum to £30,000. The Prince opened for himself an influential sphere of action in the promotion of science and art, and as patron of useful and philanthropic associations; and he completely succeeded in living down the insular jealousy of the foreigner, which was for a time rather strongly manifested. The Exhibition of 1851 owed much to his strong interest. In Continental politics his ruling idea was that Prussia should be supreme in Germany. Balmoral (q.v.) was bought by him for the Highland home of the royal house. He died of typhoid fever at Windsor Castle on the 14th December 1861; and sorrow for his death darkened the life of his bereaved widow, and largely withdrew Queen Victoria from public life.

See his *Life* by Sir Theodore Martin (5 vols. 1874-80), and Count Vitzthum's *Reminiscences* (Eng. trans. 1887). For his careful but not wholly judicious training of his eldest son, see the article on Edward VII in the 1912 Supplement to the *Dictionary of National Biography*. For the rest, see the article VICTORIA, and books there cited.

Albert is a river of Queensland flowing 200 miles to the Gulf of Carpentaria; a county in South Australia, on the Murray; a county in New Brunswick, on the Bay of Fundy; and a district in the Cape Province of South Africa.

Albert was the name by which Alexandre Martin (born 1815), socialist, was commonly known. He was conspicuous in the 1848 Revolution, an associate of Louis Blanc (q.v.), promoted the *Ateliers Nationaux* (q.v.), was a member of the provisional government, and for joining in an *emeute* was next imprisoned, and last heard of as a Communist during the siege of Paris in 1870.

Alberta, a province of the Dominion of Canada, is bounded on the south by the 49th parallel of north latitude, on the west by British Columbia, on the north by the 60th parallel of north latitude, on the east by the 4th meridian in the Dominion system of land surveys (110° west longitude). Land area, 252,925 sq. m.; water area, 2360 sq. m.; total area, 255,285 sq. m., more than twice as large as Great Britain and Ireland, and larger than any European country except Russia. It is a vast plateau along the eastern ridge of the Rocky Mountains, 3000 feet above the sea at its southern boundary, and sloping to a level of less than 1000 feet along its northern limit. The southern half of the province is a treeless, undulating prairie, scored by deep river-valleys and covered with a rich chocolate soil well suited for agriculture. The northern part is more varied, comprising stretches of forest along the rivers and lakes; hills and level plains covered with numerous and extensive groves of spruce, aspen, poplar, and willow, or tall rank grass and flowers, giving the landscape a pleasing and park-like appearance. Two of the largest river systems of North America traverse the plains of Alberta—the Saskatchewan and the Peace. The Saskatchewan drains the southern half of the province eastward into Lake Winnipeg, the waters of which finally reach Hudson Bay *via* Nelson River. It has two large branches, the North Saskatchewan, 760 miles long, with its tributaries, the Battle, 500 miles, and the Brazeau, 150 miles; the South Saskatchewan, 865 miles long, with its tributaries, the Belly, 180 miles, the Bow, 315 miles, and the St Mary's, 120 miles. Peace River, 1065 miles long, and the Athabasca, 765 miles long, form part of the great Mackenzie system, and drain the northern half of Alberta into the Arctic Ocean. The Smoky, 245 miles, and the Little Smoky, 180 miles, are the

largest tributaries of the Peace. The Pembina, 210 miles, flows into the Athabasca, the latter joining the Peace at Lake Athabasca. Both the Peace and Athabasca are navigable for hundreds of miles, and freight-boats make regular trips in summer.

The population of the territory that is called Alberta to-day was 18,075 in 1881. At the census of 1891 it was 22,277; of 1901, 73,022; of 1906, 185,412; of 1921, 581,995, a large majority of whom were males. In 1906 the nationality of the population was as follows: Canadians, 86,818; British, 24,320; United States, 43,251; foreign, 30,418. The principal cities are Edmonton, the capital of the province, population 54,000; Calgary, 57,000; Lethbridge, 10,000; Medicine Hat, 10,000; Strathcona; Wetaskiwin.

The province was organised in 1905 by the Alberta Act, whereby provincial autonomy was established in the Canadian Confederation. The government is administered by a Lieutenant-governor appointed by the Dominion government for a term of five years, acting by the advice of the Provincial Executive of four members, directed by the Legislative Assembly, elected every four years by male and female suffrage. Representation in the local and federal parliaments is readjusted every five years to give adequate representation by population. Education is provided for by a free system of common schools, a provincial Normal School for the training of teachers, and the state university, opened in 1908, and having 335 students in 1916-17.

Agriculture is the chief industry of Alberta; though ranching is carried on, especially in the foothills of the Rocky Mountains. Over 100,000,000 acres are fit for cultivation; about 8 per cent. was in 1919 under crop. The soil is very fertile, being composed of a marly clay subsoil deeply covered with humus well adapted for growth of cereals, clovers, and vegetables. Great attention is paid to the breeding of horses and cattle. The luxuriant grasses, pure and abundant water, and dry winter climate constitute favourable conditions for livestock. Creameries, factories, and farm dairies in the province produced in 1917 23,000,000 lb. of butter and 1,278,000 lb. of cheese. The principal manufactures are sawn lumber, bricks, cement, refined clay products, pork-packing, beef-canning, and milling. Cheap coal is mined within the province. Alberta has 16,588 sq. m. of coal-lands, estimated to contain 89,330,000,000 tons, mostly lignite. All the rivers flowing from the Rocky Mountains carry gold in the gravels. Graphite and gypsum exist in the Rocky Mountains, and there is copper in quantity in the vicinity of Lake Athabasca. Natural gas is used extensively in Medicine Hat for heating, power, and lighting purposes, and is available in the north along the Athabasca River. In 1904 the railway system increased from 650 miles to 2700; and in 1917 it exceeded 4500 miles.

Free land is obtained under regulations framed by the Dominion government. Each person is eligible for 160 acres, on settlement conditions, for a registration fee of \$10. Improved farms may be had at prices from \$15 to \$45 per acre. Railway companies have large tracts for sale. Irrigation is extensively carried on in the southern portion of the province, where the rainfall is in some years deficient. Four parks have been set aside in Alberta by the Dominion government for the preservation of the *fauna* of the country. Banff National Park and Jasper Park (5450 sq. m.) are situated in the Rocky Mountains. Buffalo Park (530 sq. m.) is set apart for the preservation of the bison, and has one of the largest herds now left in the world. Elk Island Park is set apart for the preservation of the deer family.

Albert-Edward. See EDWARD VII.

Albert-Edward Nyanza, or LAKE EDWARD, as it is now called, a lake of Equatorial Africa, discovered by Stanley in 1876. It occupies the southern end of a vast natural depression, of which the Albert Nyanza fills the northern extremity; is due south of the mountain mass of Ruwenzori; and is surrounded by wide grassy plains, over which it once seems to have extended. Its length seems to be about 50 miles, the breadth a little less, the general shape being somewhat circular; but there is a north-eastern extension (Dweru) 25 miles long, connected with the lake by a channel not above from 400 to 1000 yards wide. According to the Anglo-Congolese boundary commission of 1906-7, its height above the sea is not, as had been said, 2240 feet, but 3000 feet. South-east is the Mfumbiro mountain mass. The commission recommended that the name should be simplified (as that of King Edward VII. had been) to Lake Edward. The water of the lake flows into the Albert Nyanza by the Semliki River, 130 miles long

Albertite. See BITUMEN.

Albert Lea, Minnesota, on a lake of the same name, about 100 miles S. of St Paul, has a pop. of 8000.

Albert Medal, a decoration which, in its original institution in 1866, was intended to reward heroic acts of mariners and others in saving life at sea. A warrant of April 12, 1867, in place of the one decoration, instituted two, called the Albert Medal of the First Class, and the Albert Medal of the Second Class. In April 1877, the Albert Medal was extended to acts of gallantry in preventing loss of life in mines, on railways, at fires, and in other perils on land. The decoration of the First Class for saving life at sea is shown in the figure, and consists of a gold oval badge enamelled in dark blue, surrounded with a Garter in bronze, with the inscription in gold raised letters. It is suspended from a dark-blue and white striped ribbon. The decoration of the First Class for saving life on land is similar, except that the enamel is red, the anchor omitted, and the word 'land' in the inscription replaces 'sea.' The ribbon is crimson and white. The badge of the Second Class differs in each case from that described by being all in bronze. A bar is attached to the ribbon as a reward for every subsequent act of bravery. At the beginning of the 20th century there were 15

First-class and over 50 Second-class holders of the medal for saving life at sea, and 13 First-class and above 60 Second-class holders of that for saving life on land.—ALBERT MEDAL is also the name of a distinction granted since 1864 by the Society of Arts. It was founded to reward distinguished merit in promoting arts, manufactures, or commerce; and has been conferred on many of the most notable men of science, engineers, and inventors in Britain, America, and France.

Albert Nyanza (Mwutan Nzige, Luta Nzige), a large lake of East Central Africa, is situated in a deep rock-basin, 80 miles NW. of the Victoria Nyanza. It is of an oblong shape, just about 100 miles long from N. to S., and 25 broad. On the E. it is fringed by precipitous cliffs, with isolated peaks rising 5000 feet above it. The lake itself lies 2400 feet above the sea, and 1400 feet below the general level of the country; its water is fresh and sweet, and it is of great depth towards the centre. The N. and W. shores of the lake are

bordered by the Blue Mountains, nearly 10,000 feet in height. The existence of this vast lake first became known to Europeans through Speke and Grant in 1862; in 1864 Sir Samuel Baker was the first European to visit it, and named it after the Prince-Consort. In 1887 Emin Pasha recorded his conviction that the western part of the lake was filling up; on its shores Stanley met Emin in 1889; and Captain Lugard came hither from Uganda in 1890. The lake is a great reservoir or back-water of the Nile. The Somerset-Nile runs into its north-east corner, and the Nile issues out of its north-west corner. To the south-east of it lies the country of Unyoro. It has recently been proposed to dam this lake, so as to regulate the rising of the Nile, and improve the irrigation of Egypt.

Albert River, North Queensland, traverses a grassy plain, and falls into the Gulf of Carpentaria, below Burketown, after a total course of about 200 miles. It is connected by a cross branch with another nearly parallel stream, the Gregory. The climate of its basin is tropical, and the land is partly occupied for grazing purposes.

Albertus Magnus, COUNT OF BOLLSTADT, the great scholastic philosopher of the first half of the 13th century, was born at Lauingen, in Swabia, in 1193. After finishing his studies at Padua, he entered the lately-founded order of the Dominican friars, and taught in the schools of Hildesheim, Ratisbon, and Cologne, where Thomas Aquinas became his pupil. In 1245 he repaired to Paris, where for some years he publicly expounded the doctrines of Aristotle. In 1254 he became provincial of the Dominican order in Germany. In 1260 he received from Pope Alexander IV. the bishopric of Ratisbon. But in 1262 he retired to his convent at Cologne to devote himself to literary pursuits, and here he composed many of his works. He had fallen into dotage some years before his death, which occurred in 1280. The extensive chemical and mechanical knowledge which, considering the age in which he lived, Albertus Magnus possessed, brought upon him the imputation of being a sorcerer and magician. Jammy, a Dominican, published the works of Albertus in 21 folio vols. in 1651; and some of them, as also the apocryphal *De Secretis Mulierum* attributed to him, have been published separately. The most notable are the *Summa Theologiae* and the *Summa de Creaturis*. Albertus excelled all his contemporaries in the wideness of his learning; he was not inaptly termed the *doctor universalis*. He was not so remarkable for originality; and was to the best of his ability a faithful follower of Aristotle as presented by Jewish, Arabian, and western commentators. He stood midway between Realists and Nominalists in philosophy, and did more than any predecessor to bring about that marvellous union of theology and Aristotelianism which is the basis of scholasticism. Both in physics and metaphysics he mainly repeats Aristotle. See ALCHEMY, SCHOLASTICISM, and works by Sighart (1857; trans. 1876), D'Assailly (1870), and Bach (1881).

Albi, capital of the department of Tarn in the south of France, is built on a height near the Tarn, a tributary of the Garonne, 42 miles by rail NE. of Toulouse. It is very old, and suffered greatly during the religious wars which devastated the land in the time of the Albigenes, who took their name from this place. Besides the usual government offices, it possesses a public library and a museum and theatre. The chief buildings are the cathedral (1282-1512), the old fortress, and the archbishop's palace. Pop. 27,000.

Albigenses is a name applied loosely to the 'heretics,' belonging to various sects, who abounded in the south of France about the beginning of the

13th century. They are heard of nearly two centuries earlier, and were regarded as Manichæans; the position and prominence in their system of evil have certainly a Manichaean look. Sabatier and others identify them with the Cathari (q.v.), whose doctrines were a mixture of Buddhism, Mazdeism, and Agnosticism, and so eminently heretical by the most liberal standard. Though the Catholics charged them with unnatural vices, they professed apostolical Christianity and pure or even ascetic morals. After their condemnation by Pope Calixtus II., at the council held at Toulouse in 1119, they were usually styled the 'Toulouse heretics.' The Toulouse judgment was confirmed by Innocent II. in 1139. At a council held at Lombez, near Albi, in 1176, they spoke out more openly in defence and explanation of their doctrines; but in spite of this, they were accused later of dualism, of denying the dogmas of the Trinity and the death and resurrection of Jesus, and of refusing the eucharist and marriage. It should be remembered that the only accounts of them that we possess, have come to us through the medium of embittered and unscrupulous antagonists. The name arose from the circumstance that the district of Albigeois in Languedoc—now in the department of Tarn, of which Albi is the capital—was the first point against which the crusade of Pope Innocent III. (1209) was directed. The immediate pretence of the crusade was the murder of the papal legate and inquisitor, Peter of Castelnau, who had been commissioned to extirpate heresy in the dominions of Count Raymond VI. of Toulouse; but its real object was to deprive the count of his lands, as he had become an object of hatred from his toleration of the heretics. It was in vain that he had submitted to the most humiliating penance and flagellation from the hands of the legate Milo, and had purchased the papal absolution by great sacrifices. The legates, Arnold, abbot of Cîteaux, and Milo, stormed Béziers, the capital of Raymond's nephew, Roger, and massacred 20,000—some say 40,000—of the inhabitants, Catholics as well as heretics. That Arnold cried, 'Kill them all; God will know his own!' is denied. Simon, Count of Montfort (q.v.), who conducted the war under the legates, proceeded in the same relentless way with other places in the territories of Raymond and his allies. Of these, Roger of Béziers died in prison, and Peter I. of Aragon fell in battle. The conquered lands were given as a reward to Simon of Montfort, who never came into quiet possession of the gift. At the siege of Toulouse (1218), he was killed by a stone, and Counts Raymond VI. and VII. disputed the possession of their territories with his son. But the papal indulgences drew fresh crusaders from every province of France to continue the war. Raymond VII. continued to struggle bravely against the legates and Louis VIII. of France, to whom Montfort had ceded his pretensions, and who died during the war in 1226. After thousands had perished on both sides, and the finest parts of Provence and Upper Languedoc had been devastated, a peace was concluded in 1229, at which Raymond purchased relief from the ban of the church by immense sums of money, gave up Narbonne and several lordships to Louis IX., and had to make his son-in-law, the brother of Louis, heir of his other possessions. These provinces, hitherto independent, were thus, for the first time, joined to the kingdom of France; and the pope sanctioned the acquisition, in order to bind Louis more firmly to the papal chair, and induce him more readily to admit the Inquisition. The heretics were handed over to the proselytising zeal of the order of Dominicans and the bloody tribunals of the Inquisition; and both used their utmost power to bring the reculant Albigenes to the stake, and

also, by inflicting severe punishment on the penitent converts, to inspire a wholesome dread of re-incurring the displeasure of the church. From the middle of the 13th century, the name Albigenes gradually disappears. The remnants of them took refuge in the east, and settled in Bosnia, but there also they soon became extinct.

Compare Faber, *Inquiry into the History and Theology of the Vallenses and Albigenes* (Lond. 1838); Hahn, *Geschichte der Ketzer im Mittelalter* (1845); Schmidt, *La Secte des Cathares ou Albigeois* (1849); Peyrat, *Histoire des Albigeois* (1882); Tocco, *Eresia nel Medio Evo* (1884); Lea, *History of the Inquisition* (1888).

Albînos (Portuguese, from Lat. *albus*, 'white')—called also Leucoethiopes, or white negroes, and by the Dutch and Germans Kakerlaken—were at one time considered a distinct race; but closer observation has shown that the same phenomenon occurs in individuals of all races, and that the peculiar appearance arises from an irregularity in the skin, which has got the name of *leucopathy* or *leucosis*. It consists in the absence of the colouring matter which, in the normal state, is secreted in the deepest layer of the cuticle, and also of the dark pigment of the eye; so that the skin has a pale, sickly white colour, while the iris of the eye appears red, from its great vascularity. As the pigment in the coats of the eye serves to diminish the stimulus of the light upon the retina, albinos generally cannot bear a strong light; on the other hand, they see better in the dark than others. The colouring matter of the hair is also wanting in albinos, so that their hair is white. All these differences are of course more striking in the darker varieties of the species, and most of all in the negro albinos. Albinism is always born with the individual, and occurs not only in men, but also in other mammalia, in birds, and probably in insects. The peculiarity may be inherited. The opinion that albinos are distinguished from other men by weakness of body and mind is completely refuted by facts. See Karl Pearson's monograph in *Man* (1913).

Albion, the ancient name of the island of Britain. See **ALBANY**.

Albion, a city of Michigan, U.S., 96 miles W. of Detroit, in the centre of a grain district, is the seat of a Methodist Episcopal college (1835); pop. 8400.—**ALBION**, in New York, 30 miles W. of Rochester, is a fruit-canning and agricultural centre, with a beautiful cemetery; pop. 5000.

Albion Metal. See **ALLOY**.

Alboin, the founder of the Lombard dominion in Italy, succeeded his father in 561 A.D. as king of the Lombards, who were at that time settled in Pannonia. His thirst for action first showed itself in aiding Narses against the Ostrogoths; and afterwards, in a war with the Gepidæ, whom he, in conjunction with the Avars, defeated in a great battle (566), slaying their king Kunimond with his own hand, and marrying his daughter Rosamond. Report brought back by some of his warriors, who had accompanied Narses into Italy, determined Alboin, in 568, to invade it with his own nation of Lombards, the remains of the Gepidæ, and 20,000 Saxons. He soon overran and subdued the country as far as the Tiber, fixing his principal residence at Pavia, which long continued to be the Lombard capital; but in 574 his cruelty cost him his life. During a feast at Verona, he made his queen drink out of the skull of her father, which he had turned into a wine-cup; and she, in revenge, incited her paramour to murder him. Strangely enough, Alboin was a just and beneficent ruler. He was beloved by his subjects, whom he stimulated into that fierce energy which characterised their descendants for ages. For several centuries his name continued

famous among the Teutonic nations. Rosamond fled to Longinus, the exarch, at Ravenna. Longinus becoming her suitor, she administered poison to her paramour, who, discovering the treachery, caused her to drain the cup and share his death.

Alboni, MARIETTA (1826-94), contralto singer, was born at Cesena in the Romagna, sang in London (1847) and other European capitals, but retired from the stage after marrying the Count de Pepolo. Her second husband was M. Zieger.

Albornoz, GIL ALVAREZ CARILLO, born at Cuenca in 1300, became Archbishop of Toledo, took part in the wars against the Moors, saved the life of Alfonso XI. of Castile in battle, and commanded at the siege of Algeiras, where the king dubbed him knight. On account of the Christian boldness with which he denounced the criminal excesses of Peter the Cruel, he had to flee to Pope Clement VI. at Avignon, who made him a cardinal. Innocent VII. sent him as cardinal-legate to Rome; and Pope Urban V. appointed him legate at Bologna, where he died in 1367.

Albrét, JEANNE D'. See JEANNE D'ALBRÉT.

Albuera, in the Spanish province of Estremadura, an insignificant hamlet, famous for the sanguinary battle of May 16, 1811, between the combined English, Spanish, and Portuguese forces under General Beresford, and the French under Marshal Soult, who were scarcely so numerous, but had abundant artillery. Soult's object was to compel the English to raise the siege of Badajoz, but he was obliged to retreat to Seville, with the loss of 9000 men; whilst the allied forces lost about 7000.

Albufera (Arabic, 'the lagoon'), a lake near Valencia, in Spain, about 12 miles in length and 4 in breadth, divided from the sea by a narrow tongue of land; canals connect it with the sea and Valencia. It is rich in fish and fowl. The revenues of the domain were granted by the Spaniards to Wellington.

Albugo is a term employed in Surgery to designate the white opacity that often follows ulceration of the cornea of the eye. In infancy, the comparatively rapid interchange of materials will often diminish to a great extent both the extent and density of these spots; but in after-life they do not undergo similar absorption, nor are they amenable to surgical relief. The disease is also called *Leucoma*.

Albula, a pass and mountain stream in the Swiss canton of Grisons. The pass (elevation, 7595 feet) is a marshy plateau, three-fourths of a mile long, with granite and limestone summits towering on either side of it. The stream rises close by, and after a course of 20 miles, broken by numerous picturesque waterfalls, it joins a tributary of the Rhine.

Album (Lat., 'white'), amongst the Romans, was a white tablet overlaid with gypsum, on which were written the *Annales Maximis* of the pontifex, edicts of the prætor, and rules relative to civil matters. It was so called, either because it was composed of a white material, or because the letters used were of that colour. In the middle ages, the word was used to denote any list, catalogue, or register, whether of saints, soldiers, or civil functionaries. In the universities on the Continent, the list of the names of the members is called the album. But its popular signification in modern times is that of a book for containing photographs, or a blank book for a drawing-room table, and intended to receive fugitive pieces of verse, or the signatures of distinguished persons, or sometimes merely drawings, prints, marine plants, postage stamps, and the like. Another modern use of the

word is as applied to collections of engravings of specimen pictures of distinguished artists—as a Murillo album, or a Rembrandt album.

Albumen is a term used in Physiological Chemistry and in Botany in distinct senses: (a) A definite proteid substance (now frequently spelt *Albumin*, so as to agree in form with the other organic compounds), containing carbon, hydrogen, oxygen, nitrogen, and a small percentage of sulphur, coagulable by heat, mineral acids, alcohol, ether, tannic acid, &c., and existing in animals in white of egg and blood serum, and in plants in seeds and elsewhere (see ANIMAL CHEMISTRY, PROTEINS). It is the sulphur of the albumen that blackens silver when brought in contact with eggs, and the smell of rotten eggs arises from the formation of sulphuretted hydrogen during their decomposition. The property of coagulating with heat at about 160° F. (71° C.) adapts albumen for the purpose of clarifying in sugar-refining and other processes. The albumen is added to the liquid in the cold state, allowed to mix thoroughly therein, and then, when heated, it coagulates, entangling and separating all the impurities suspended in the liquid. In cooking, the juiciness of a steak or roast depends largely on the proteid substances, coagulated by the sudden application of heat, preventing the evaporation of the juices of the meat during the subsequent slow heating required to fit it for the table. With many metallic salts, such as bichloride of mercury (corrosive sublimate), sulphate of copper (blue vitriol), acetate of lead (sugar of lead), and nitrate of silver (lunar caustic), it forms insoluble compounds, and is therefore used as an antidote to these poisons. A paste made by mixing albumen with slaked lime, sets, in a short time, to a mass of stony hardness, and, in virtue of this property, makes an admirable cement for broken earthenware, or other purposes. The importance of albumen as an article of diet will be discussed under FOOD.

(b) A botanical term, without chemical significance, applied to the store of various reserve nutritive materials laid up for the use of the embryo within the seed. The term is only applied to the nutritive tissue when it is stored apart from the embryo proper, either within the embryo-sac (*endosperm*), or round about it (*perisperm*). Seeds which have abundant nutritive reserves containing proteids, &c., may still be 'exalbuminous' when the nutritive matter is stored within the embryo itself, as in the common pea. The characters of the albumen are important in botanical diagnosis. It is sometimes very small, as in the nettle; in other instances, on the contrary, it is very much larger than the embryo, as in the coconut, of which it forms the edible part. It is sometimes *mealy* or *farinaceous*, as in the cereals; *oily*, as in the poppy; *horny*, as in coffee; *cartilaginous*, as in the coconut; *mucilaginous*, as in the mallow. Vegetable ivory is the albumen of a palm (*Phytelphas*) which grows on the banks of the Magdalena in Colombia, and is used in place of ivory. It is thus the albumen which makes many seeds valuable for edible and other purposes, though others, no less valuable, have the nutritive materials stored within the embryo. See OVULE, SEED.

Albuminuria is a name for Bright's disease of the kidneys (see BRIGHT'S DISEASE); but albumen occurs in the Urine (q.v.) of perfectly healthy persons, and varies according to circumstances—often in young adults after muscular exercise, and with some people in indigestion and after cold baths.

Albuñol, a small town of Spain, 40 miles S.E. of Granada, near the Mediterranean coast; pop. 9000.

Albuquerque, a town of Spain, 24 miles N. of Badajoz, near the Portuguese frontier. It stands

on an eminence, and is defended by a strong fortress. Pop. 9000.

Albuquerque, AFFONSO D', 'the Great,' viceroy of the Indies, was born in 1453, near Lisbon. In that age, the Portuguese people were distinguished for heroism and a spirit of adventure. They had discovered and subjugated a great part of the western coast of Africa, and were beginning to extend their dominion over the seas and the people of India. Albuquerque being appointed viceroy of these new possessions, landed on the Malabar coast in 1503, with a fleet and some troops; conquered Goa, which he made the seat of the Portuguese government, and the centre of its Asiatic commerce; and afterwards Ceylon, the Sunda Isles, the peninsula of Malacca, and (in 1515) the island of Ormuz at the entrance of the Persian Gulf. When the king of Persia sent for the tribute which the princes of this island had formerly rendered to him, Albuquerque presented bullets and swords to the ambassador, saying: 'This is the coin in which Portugal pays her tribute.' He made the Portuguese name profoundly respected among the princes and people of the East; and many of them, especially the kings of Siam and Pegu, sought his alliance and protection. He maintained strict military discipline, was active, far-seeing, wise, humane, and equitable, respected and feared by his neighbours, while beloved by his subjects. His virtues made such an impression on the Indian peoples, that long after his death they resorted to his grave to implore his protection against the misgovernment of his successors. Yet he did not escape the envy of courtiers and the suspicions of his king, who appointed Soarez, a personal enemy of Albuquerque, to supersede him as viceroy. This news reached him just as he was leaving Ormuz, and gave a severe shock to his shattered health. A few days after, he died at sea near Goa, December 16, 1515. His *Commentaries* were translated by Birch for the Hakluyt Soc. (4 vols. 1875-84).

Alburnum, or SAP-WOOD, is the youngest and most external portion of the wood of ordinary dicotyledonous trees. It is still imperfectly hardened, and lies between the *Bark* (q.v.) and the *heart-wood* or *Duramen* (q.v.). There is often a very marked division between it and the duramen, in trees whose age is such that the latter has been perfected. The alburnum differs from the duramen in having its tubes readily permeable by fluids (see **PHYSIOLOGY, VEGETABLE**). It gradually hardens, and is transformed into duramen, new layers being added externally. It is almost always of a white or very pale colour, whilst in many trees the duramen is highly coloured. The alburnum is pale even in ebony, in which the duramen is black. In general, the alburnum is much inferior in value to the hardened or perfected wood. See **TIMBER, WOOD**.

Albury, sometimes called the Federal City, on the New South Wales bank of the Murray River, is 190 miles N.E. of Melbourne by rail, in a fertile agricultural and pastoral district, producing wine and tobacco, with a little gold. In the wet season the Murray is navigable thus far, 1000 miles from its mouth, and is here spanned by two bridges (one for the railway). Pop. about 8000.

Alca and Alcadaë. See **AUK**

Alcæus of MITYLENE, one of the greatest lyric poets of Greece, flourished about 600 B.C. Most of his odes, in the Æolic dialect, are occupied with his grief for the dissensions of his country, his hatred of tyrants, his own misfortunes, and the sorrows of exile; in some he celebrates the praises of love and wine. He is said to have been an admirer of Sappho, who was a contemporary.

Alcæus himself took part in the civil war, first as the coadjutor of Pittacus, but afterwards against him, when he proved a tyrant. Being banished from Mitylene, he endeavoured, at the head of the other exiles, to force his way back; but in this attempt he fell into the hands of Pittacus, who, however, granted him his life and freedom. He was the inventor of the Alcaic verse, which Horace, the happiest of his imitators, transplanted into the Latin language. Of the ten books of his odes, the few fragments that remain are collected in Bergk's *Poetæ Lyrici Græci* (4th ed. 1882). The new fragments discovered by Grenfell and Hunt are too fragmentary to add to our knowledge or modify our ideas of Alcæus.

Alcahest. See **ALCHEMY**.

Alcala' de Guadaira, a summer-resort of Spain, near the Guadaira, 9 miles E. by S. from Seville, is celebrated for its bread. Seville is chiefly supplied from it. Pop. 10,000.

Alcala' de Henares, a town in Spain, Cervantes's birthplace, on the Henares, 21 miles E. of Madrid by rail. It once boasted of a university, founded by the famous Cardinal Ximenes in 1510, which enjoyed a European fame, and was attended by thousands of students. It was removed to Madrid in 1836, and the town is now not a shadow of its former self. Here was printed in 1517, in six folio volumes, at an expense of 80,000 ducats, the great Complutensian Bible, a monument of the piety and learning of the great cardinal. The chief buildings are the Colegio de San Ildefonso, the seat of the ancient university; the Colegiata (restored 1908), containing the founder's monument; the archbishop's palace; the cathedral; and the church of Santa Maria, in which Cervantes was baptised, October 9, 1547. The house in which he was born is marked by an inscription. Pop. 10,000. The *Complutum* of the Romans, the town owes its modern name to the Moors, under whom it was *Al-Kalat*, 'the castle.'

Alcala' la Re'al ('the royal castle'), a city of Andalusia, Spain, in the province of Jaen, and 26 miles NW. of Granada. It is situated on a high plateau, and is a very picturesque town, irregularly built, with steep and narrow streets and bold towers. It was a strong fortress under the Moors, but was taken in 1340 by Alfonso XI. in person, whence it obtained the name *Real*. The neighbourhood produces grain and fruits of the finest quality, and there is some trade in wine and wool. Pop. 20,000.

Alcal'de, a corruption of the Arabic *al-qadi*, 'the judge.' It is still used in Spain as the general title for the elected president of the council of the commune, who exercises both judicial and magisterial offices. See **CADI**.

Al'camo, a quaint old town of Sicily, 52 miles SW. of Palermo by rail. Originally founded by the Saracens, it stood on the neighbouring Monte Bonifato (2713 feet), and long retained a Moslem population, who were driven out by the Emperor Frederick II. in 1233, when the new town was built at the foot of the hill. Pop. 50,000.

Alcañiz, a town of Aragon, Spain, in the province of Teruel, 63 miles S.E. from Saragossa, on the Guadalope. It has a magnificent collegiate church. Pop. 8000.

Alcantara (Arabic, 'the bridge'), an old Spanish town in Estremadura, on a rocky height above the Tagus, near the Portuguese frontier. The bridge from which it takes its name was built under Trajan, 105 A.D. It consists of six arches; the whole length is 670, and the height 210 feet. It has twice been partially blown up in time of war, but the larger part is still intact. Pop. 3500.

THE ORDER OF ALCANTARA, one of the religious orders of Spanish knighthood, was founded in 1156 as a military fraternity for the defence of Estremadura against the Moors. In 1177, Pope Alexander III. raised it to the rank of a religious order of knighthood; and the grand-mastership of the order was by Pope Alexander VI. united to the Spanish crown in 1494. The order came to be richly endowed. The knights, who follow the rule of St Benedict, take the usual vows of obedience and poverty, a special vow also binding them to defend the immaculate conception of the Virgin. In the nineteenth century the order was several times suppressed, and as often restored. Thus it was suppressed in 1872, and restored again in 1874.

Alcantara, a seaport town of Brazil, in the province of Maranhão, on the Bay of St Marcos. Pop. 20,000.

Alcaraz, a town of La Mancha, Spain, 36 miles WSW. of Albacete. A ruined castle crowns the summit of the hill; and there are also the remains of a fine Roman aqueduct. Pop. 5,000.

Alcaudete (ancient *Uditunum*), a town of Spain, 22 miles SW. of Jaen. Pop. of commune, 10,000.

Alcazar de San Juan (ancient *Alce*), a town of Spain, in the province of Ciudad Real, 92 miles SSE. of Madrid by rail. Pop. 12,000.

Alcazar-kebir, a city of Morocco, about 80 miles NW. of Fez, with considerable trade. In a battle here in 1578, Sebastian, king of Portugal, was defeated and slain by the Moors. Pop. nearly 9000, many Jews.

Alcedo. See KINGFISHER.

Alcestis, the wife of Admetus, king of Phææ in Thessaly. The god Apollo tended her husband's flocks when exiled from heaven for having slain the Cyclopes, and out of gratitude for his kindly treatment, prevailed upon the Fates to grant Admetus deliverance from death, if his father, mother, or wife should die in his stead. When the fatal hour arrived, Alcestis alone was found ready to give up her life for his. She was brought back to her husband from the lower world by Hercules. Alcestis is the subject of a noble tragedy by Euripides, which Browning has translated, and she appears as Chaucer's highest ideal of womanhood in the Prologue to his *Legende of Goode Women*. The allusion to her story in one of the finest of Milton's sonnets will be remembered.

Alchemilla. See LADY'S MANTLE.

Alchemy is to modern chemistry what astrology is to astronomy, or legend to history. In the eye of the astrologer, a knowledge of the stars was valuable only as a means of foretelling, or even of influencing, future events. In like manner, the genuine alchemist toiled with his crucibles and alembics, calcining, subliming, distilling, not with a view to discover the chemical properties of substances, as we understand them, but with two grand objects, as illusory as those of the astrologer—to discover, namely, (1) the secret of transmuting the baser metals into gold and silver, and (2) the means of indefinitely prolonging human life.

The word is derived from the Arabic *alkīmīa*, compounded of the Arabic article and a Greek word *chēma*, used in Diocletian's decree against Egyptian works treating of the *chēma* (transmutation) of gold and silver. The Greek word is now most usually explained to mean 'the Egyptian art,' and derived from the Egyptian name for Egypt, *Khmi*; but it was ultimately confounded with the true Greek *chumera*, pouring, infusion. The latter form, which was possibly, however, the real original of *chēma*, justifies the Renaissance spellings, *alchymy* and *chymistry*.

Tradition points to Egypt as the birthplace of the science. Hermes Trismegistus is represented as the father of it; but it should be remembered that the speculations of some of the early Greek philosophers, as of Empedocles, who first named the four elements, pointed in the direction of a rudimentary chemical theory. Zosimus the Theban discovered in sulphuric acid a solvent of the metals, and liberated oxygen from the red oxide of mercury. The students of the 'sacred art' at Alexandria believed in the transmutation of the four elements. The Roman emperor Caligula is said to have instituted experiments for producing gold out of orpiment (sulphuret of arsenic); and in the time of Diocletian, the passion for this pursuit, conjoined with magical arts, had become so prevalent in the empire, that that emperor is said to have ordered all Egyptian works treating of the chemistry of gold and silver to be burnt. For at that time multitudes of books on this art were appearing, written by Alexandrine monks and by hermits, but bearing famous names of antiquity, such as Democritus, Pythagoras, and Hermes.

At a later period, the Arabs, who had enthusiastically adopted Aristotle from the Greeks, appropriated the astrology and alchemy of the Persians and the Jews of Mesopotamia and Arabia; and it is to them that European alchemy is directly traceable. The school of polypharmacy, as it has been called, flourished in Arabia during the califates of the Abbasides. The earliest work of this school now known is the *Summa Perfectionis*, or 'Summit of Perfection,' composed by Gebir (q.v.) in the 8th century; it is consequently the oldest book on chemistry proper in the world. It contains so much of what sounds very much like jargon in our ears, that Dr Johnson (erroneously) ascribed the origin of the word 'gibberish' to the name of the compiler. Yet when viewed in its true light, it is a wonderful performance. It is a kind of text-book, or collection of all that was then known and believed. It appears that these Arabian polypharmacists had long been engaged in calcining and boiling, dissolving and precipitating, subliming and coagulating chemical substances. They worked with gold and mercury, arsenic and sulphur, salts and acids; and had, in short, become familiar with a large range of what are now called chemicals. Gebir discovered corrosive sublimate, the process of cupellation of gold and silver, and distillation. He taught that there are three elemental chemicals—mercury, sulphur, and arsenic. These substances, especially the first two, seem to have fascinated the thoughts of the alchemists by their potent and penetrating qualities. They saw mercury dissolve gold, the most incorruptible of matters, as water dissolves sugar; and a stick of sulphur presented to hot iron penetrates it like a spirit, and makes it run down in a shower of solid drops, a new and remarkable substance, possessed of properties belonging neither to iron nor to sulphur. The Arabians held that the metals are compound bodies, made up of mercury and sulphur in different proportions. With these very excusable errors in theory, they were genuine practical chemists. They toiled away at the art of making 'many medicines' (polypharmacy) out of the various mixtures and reactions of such chemicals as they knew. They had their pestles and mortars, their crucibles and furnaces, their alembics and aludels, their vessels for infusion, for decoction, for cohabitation, sublimation, fixation, lixiviation, filtration, coagulation, &c. Their scientific creed was transmutation, and their methods were mostly blind gropings; and yet, in this way, they found out many a new body, and invented many a useful process. To the Arab alchemists we owe the terms alcohol, alkali, borax, elixir.

From the Arabs, alchemy found its way through

Spain into Europe generally, and speedily became entangled with the fantastic subtleties of the scholastic philosophy. In the middle ages it was chiefly the monks that occupied themselves with alchemy. Pope John XXII. took great delight in it, but denounced the searchers for gold 'who promise more than they can perform,' and the art was afterwards forbidden by his successor. The earliest authentic works on European alchemy now extant are those of Roger Bacon (1214-94) and Albertus Magnus (1193-1280). Roger Bacon (q.v.), who was acquainted with gunpowder, condemns magic, necromancy, charms, and all such things, but believes in the convertibility of the inferior metals into gold. Still, he does not profess to have ever effected the conversion, an idea which took firm possession of the imagination and, latterly, of the avarice of the middle ages. Their conception was that gold was the perfect metal, and that all other metals were so many removes or deflections from gold, in consequence of arrestment, corruption, or other accidents. Now, though gold, being simply perfect, could not, if mixed with the imperfect, perfect the latter, but would rather share its imperfections; yet, were a substance found many times more perfect than gold, it might well perfect the imperfect. Such a substance would be composed of purest mercury and sulphur, commingled into a solid mass, and matured by wisdom and artificial fire into possibly a thousand thousand times the perfection of the simple body. This was the philosopher's stone which so many devotees of alchemy in the middle ages toiled in vain to fabricate. Roger Bacon followed Gebir in regarding potable gold—that is, gold dissolved in nitro-hydrochloric acid or *aqua regia*—as the elixir of life. Urging it on the attention of Pope Nicholas IV., he informs his Holiness of an old man who found some yellow liquor (the solution of gold is yellow) in a golden phial, when ploughing one day in Sicily. Supposing it to be dew, he drank it off. He was thereupon transformed into a hale, robust, and highly accomplished youth.—Albertus Magnus (q.v.) had a great mastery of the practical chemistry of his times; he was acquainted with alum, caustic alkali, and the purification of the royal metals by means of lead. In addition to the sulphur-and-mercury theory of the metals, drawn from Gebir, he regarded the element water as still nearer the soul of nature than either of these bodies. He is the first to speak of the affinity of bodies, a term he uses in reference to the action of sulphur on metals.—Thomas Aquinas (q.v.) also wrote on alchemy, and was the first to employ the word *Amalgam* (q.v.).—Raymond Lully (q.v.) is another great name in the annals of alchemy. He was the first to introduce the use of chemical symbols, his system consisting of a scheme of arbitrary hieroglyphics. He made much of the spirit of wine (the art of distilling spirits would seem to have been then recent), imposing on it the name of *aqua vite ardens*. In his enthusiasm, he pronounced it the very elixir of life.—Basil Valentine (q.v.) used to get the credit of having, about the end of the 15th century, introduced antimony into medical use. He, it was said, regarded salt, sulphur, and mercury as the three bodies contained in the metals; and he inferred that the philosopher's stone must be a compound of salt, sulphur, and mercury, so pure that its projection on the baser metals should be able to work them up into greater and greater purity, bringing them at last to the state of silver and gold. But as it has been proved that 'Basil Valentine' is but an assumed name for Johann Thölde, writing in the middle of the 17th century, the attribution of these views to a writer of the 15th century has brought confusion into this part of the history.

But more famous than all was Paracelsus (q.v.),

in whom alchemy proper may be said to have culminated. He held, with Basil Valentine, that the elements of compound bodies were salt, sulphur, and mercury—representing respectively earth, air, and water, fire being already regarded as an imponderable—but these substances were in his system purely representative. All kinds of matter were reducible under one or other of these typical forms; everything was either a salt, a sulphur, or a mercury, or, like the metals, it was a 'mixt' or compound. There was one element, however, common to the four; a fifth essence or 'quintessence' of creation; an unknown and only true element, of which the four generic principles were nothing but derivative forms or embodiments: in other words, he inculcated the dogma, that there is only one real elementary matter—nobody knows what. This one prime element of things he appears to have considered to be the universal solvent of which the alchemists were in quest, and to express which he introduced the term *alcahest*. He seems to have had the notion, that if this quintessence or fifth element could be got at, it would prove to be at once the philosopher's stone, the universal medicine, and the irresistible solvent. An often-quoted saying of his is '*Vita ignis, corpus lignum*' (Life is the fire, the body the fuel).

After Paracelsus, the alchemists of Europe became divided into two classes. The one class was composed of men of diligence and sense, who devoted themselves to the discovery of new compounds and reactions—practical workers and observers of facts, and the legitimate ancestors of the positive chemists of the era of Lavoisier. The other class took up the visionary, fantastical side of the older alchemy, and carried it to a degree of extravagance before unknown. Instead of useful work, they compiled mystical trash into books, and fathered them on Hermes, Aristotle, Albertus Magnus, Paracelsus, and other really great men. Their language is a farrago of mystical metaphors, full of 'red bridegrooms' and 'lily brides,' 'green dragons,' 'ruby lions,' 'royal baths,' 'waters of life.' The seven metals correspond with the seven planets, the seven cosmical angels, and the seven openings of the head—the eyes, the ears, the nostrils, and the mouth. Silver was Diana, gold was Apollo, iron was Mars, tin was Jupiter, lead was Saturn, and so forth. They talk for ever of the powder of attraction, which drew all men and women after the possessor; of the alkahest or universal solvent, and the grand elixir, which was to confer immortal youth upon the student who should approve himself fit to kiss and quaff the golden draught. There was the great mystery, the mother of the elements, the grandmother of the stars. There was the *philosopher's stone*, and there was the *philosophical stone*. The philosophical stone was younger than the elements, yet at her virgin touch the grossest calx (ore) among them all would blush before her into perfect gold. The philosopher's stone, on the other hand, was the first-born of nature, and older than the king of metals. Those who had attained full insight into the arcana of the science were styled Wise; those who were only striving after the light were Philosophers; while the ordinary practisers of the art were called Adepts. It was these visionaries that formed themselves into Rosicrucian Societies and other secret associations. It was also in connection with this mock-alchemy, mixed up with astrology and magic, that quackery and imposture so abounded, as is depicted by Scott in the character of Dousterswivel in the *Antiquary*. Designing knaves would, for instance, make up large nails, half of iron and half of gold, and lacker them, so that they appeared common nails; and when their credulous and avaricious dupes saw them extract

from what seemed plain iron an ingot of gold, they were ready to advance any sum that the knaves pretended to be necessary for pursuing the process on a large scale. It is from this degenerate and effete school that the prevailing notion of alchemy is derived—a notion which is unjust to the really meritorious alchemists who paved the way for genuine chemistry. In 1782 Dr Price of Guildford exhibited to George III. some specimens of gold he affirmed he had made from a red and white powder. Being called upon, as a member of the Royal Society, to repeat his experiments in the presence of two witnesses, after much equivocation he took poison and died (1783). Robert Boyle believed in the possibility of the alchemistic transmutations; Sir Isaac Newton in his earlier years searched for the philosopher's stone; Goethe was sympathetic. And the leading tenet in the alchemists' creed—the transmutability of other metals into gold and silver, a doctrine it was thought modern chemistry had utterly exploded—receives not a little countenance from some of the facts in connection with Allotropy (q.v.), but especially from the proof that the emanation from Radium (q.v.) is transformed into helium. Probably radium itself arises by a similar transformation from uranium; perhaps lead is what remains of the radium emanation when the helium is removed; and cognate speculations point to the production of gold from baser metals as a not quite impossible (if unprofitable) achievement.

Stanley Redgrove, *Alchemy Ancient and Modern* (1922); and Ray Lankester's presidential address to the British Association, 1906.

Alcibiades, born at Athens about 450 B.C., lost his father, Clinias, at Coronea (447), and was brought up in the house of his kinsman Pericles. His goodly person, his accomplishments, and the high position of Pericles procured him a multitude of friends and admirers. Socrates gained influence over him, but was unable to restrain his love of luxury and dissipation, stimulated by the wealth his marriage with Hipparete brought him. His public displays, especially at the Olympic games, were costly beyond belief. He first bore arms in the expedition against Potidæa (432 B.C.), where his life was saved by Socrates—a debt which eight years later he repaid at Delium, by saving, in his turn, the life of the philosopher. He seems to have taken no part in political matters till after the death of the demagogue Cleon, when Nicias brought about a fifty years' treaty of peace between Athens and Lacedæmon. Alcibiades, joining the radical party, was made commander-in-chief instead of Nicias in 420, persuaded the Athenians to alliance with Argos, Elis, and Mantinea, and stirred up afresh their ancient enmity to Sparta, with the result that they were defeated by the Spartans at Mantinea in 418. It was at his suggestion that, in 415, they engaged in the Sicilian expedition, in the command of which he and Nicias were associated. But during the preparations, one night all the statues of Hermes in Athens were mutilated. Alcibiades' enemies blamed him for this sacrilege, but postponed the impeachment till he had set sail, when they stirred up the people against him to such a degree, that he was recalled, in order to stand his trial. On the voyage home, he landed in Italy, and thence crossed to Lacedæmon, where, by conforming to the strict Spartan manners, he soon became a favourite. He induced the Lacedæmonians to send assistance to Syracuse, to form an alliance with Persia, and to support the people of Chios in their effort to throw off the Athenian yoke. He went thither himself, and raised all Ionia in revolt. But

Agis and other leading Spartans, jealous of Alcibiades' success, ordered their generals in Asia to have him assassinated. Discovering the plot, he fled to Tissaphernes, a Persian satrap, who had orders to act in concert with the Spartans. He now resumed his old manners, adopted the luxurious habits of Asia, and made himself indispensable to Tissaphernes, representing to him that it was contrary to Persia's interests entirely to disable the Athenians. He then sent word to the Athenian commanders at Samos that he would procure for them the friendship of the satrap if they would establish an oligarchy at Athens. The offer was accepted, and the supreme power vested in a council of Four Hundred. When it appeared, however, that this council had no intention of recalling Alcibiades, the army at Samos chose him for a general, desiring him to lead them to Athens. But Alcibiades did not wish to return to his native country till he had rendered it some service; and during the next four years he defeated the Lacedæmonians at Cynossema, Abydos, and Cyzicus; recovered Chalcædon and Byzantium, and restored to the Athenians the dominion of the sea. He then returned home (407), on a formal invitation, and was received with general enthusiasm. His triumph, however, was brief. He was sent back to Asia with a hundred ships; but his own ill-success against Andros, and the defeat of his lieutenant at Notium, enabled his enemies to get him superseded (406). He went into exile in the Thracian Chersonesus, and two years later crossed over to Phrygia, with the intention of repairing to the court of Artaxerxes. Historians differ as to why, and by whom the deed was done; but one night, in 404, his house was fired by a band of armed men; and, rushing out sword in hand, he fell pierced with a shower of arrows. Nature had gifted him with winning eloquence (though he stuttered in his speech, and could not articulate the letter *r*), and his in a rare degree was the power to fascinate and govern men. In all his actions, he allowed himself to be guided by circumstances, because he had no fixed principles of conduct. But he possessed the boldness that arises from conscious superiority and shrinks from no difficulty.

Alciphron, a Greek author of 118 epistles professing to be written by fishermen, countrymen, courtesans, parasites—brilliant character sketches in a pure style, some of them based on Menander's plays. He lived about 180 A.D.

Alcira, a town of Spain, in the province of Valencia, 20 miles SSW. of Valencia, with trade in silk, rice, and oranges. Pop. 20,000.

Alclyde. See STRATHCLYDE.

Alcmæon, a son of Amphiaraus and Eriphyle, was one of the heroes who took part in the successful expedition of the *Epigoni* against Thebes. He was charged by his father to put his mother to death, in revenge for her having urged her husband to take part in an expedition in which his foresight showed him he should perish. She had been gained over to urge this fatal course by a gift from Polynices of the fatal necklace of Harmonia. The matricide brought upon Alcmæon madness and the horror of being haunted by the Furies, but at Psophis he was purified by Phegeus, whose daughter he married, giving her the fatal present. But the land became barren in consequence of his presence, and he fled to the mouth of the river Achelous, the god of which gave him his daughter Callirrhoe in marriage. His new wife longed for the fatal necklace, and sent her husband to Psophis to procure it, under pretence of dedicating it at Delphi; but Phegeus, learning for whom it was really intended, caused his sons to murder the ill-fated Alcmæon.

Alcman, one of the earliest Greek lyric poets, was born about the middle of the 7th century B.C. at Sardis, in Lydia, but lived, first as a slave, and afterwards as a freedman, in Sparta. The first to write erotic poetry, he composed in the Doric dialect *Parthenia*, or songs sung by choruses of virgins, bridal-hymns, and verses in praise of love and wine. Of his scanty fragments, which are given in Bergk's *Poetae Lyrici Graeci* (4th ed. 1878), the most important is a *Parthenion*, discovered on an Egyptian papyrus at Paris in 1855.

Alcock, SIR RUTHERFORD, K.C.B., was born in 1809 in London, studied medicine there at King's College, and saw three years' service on the medical staff of the British auxiliaries in Portugal and Spain (1833-6). Sent out in 1844 as a British consul to China, he was in 1858 made consul-general in Japan, and next year received the rank of minister-plenipotentiary. This dangerous post he filled until 1865, from which year till 1871 he was envoy to the Chinese government. Made C.B. in 1860, K.C.B. in 1862, D.C.L. in 1863, and P.R.G.S. in 1876, he died 2d November 1897. Among his works are *Medical Notes on the British Legion of Spain* (1838), *The Capital of the Tycoon* (1863), and *Art in Japan* (1878). See Michie, *The Englishman in China* (1900).

Alcohol (Arab. *al-koh'l*, originally designating a collyrium, a very fine powder of antimony for staining the eyelids; afterwards 'essence', 'spirits'). Ordinary or *ethyl* alcohol is a limpid, colourless liquid, of a hot pungent taste, and having a slight but agreeable smell. It is the characteristic ingredient of fermented drinks, gives them their intoxicating quality, and is obtained from them by distillation. If we look at the extraordinary consumption of these liquors for various purposes, it is seen to be one of the most important substances produced by art.

Alcohol occurs in nature in several growing plants, and must therefore be regarded as an occasional constituent of plant-juices which have not undergone fermentation. It has been found in the fruit and pedicels of *Heracleum giganteum*, the fruit of the parsnip, and the unripe fruit of *Anthriscus cerefolium*. For practical purposes, there is, however, only one source of alcohol—namely, the fermentation of sugar or other saccharine matter. Some plants contain free sugar, and still more contain starch, which can be converted into sugar. The best vegetable substances, then, for yielding alcohol are those that contain the greatest abundance of sugar or of starch. Recently alcohol has been produced from sawdust. See DIASTASE, FERMENTATION, and DISTILLATION.

Owing to the attraction of alcohol for water, it is impossible to procure pure alcohol by distillation alone. Common spirits, such as brandy, whisky, &c. contain 50 or 52 per cent. of alcohol; in other words, they are about half alcohol, half water. *Proof-spirit*, which is the standard by means of which all mixtures of alcohol and water are judged, contains 57.27 per cent. by volume, and 49.50 per cent. by weight of alcohol. The specific gravity of proof-spirit is .9186; and when a spirit is called *above proof*, it denotes that it contains an excess of alcohol; thus, *spirit of wine*, or rectified spirit, with specific gravity .838, is 54 to 58 overproof, and requires 54 to 58 per cent. of water to be added to it to bring the strength down to that of proof-spirit; whilst the term *under-proof* has reference to a less strong spirit than the standard (see HYDROMETER). The most primitive method of learning the strength of alcohol was to drench gunpowder with it, set fire to the spirit, and if it inflamed the gunpowder as it died out, then the alcohol stood the test or proof, and

was called proof-spirit. The highest concentration possible by distillation gives 90 per cent. of alcohol, still leaving 10 per cent. of water. In order to remove this, fused chloride of calcium, quicklime, or fused carbonate of potash, is added to the alcoholic liquid, the whole allowed to stand for twelve hours, and then the spirit may be distilled off practically free from water. Spirit of wine may also be deprived of its remaining water by suspending it in a bladder in a warm place; the bladder allows much of the water to pass through and evaporate, but little of the alcohol. The latter method is called Soemmering's process, and depends on the different degrees of rapidity with which the bladder admits of water and alcohol passing through it. Thus, introduce into one bladder eight ounces of water, and into a second eight ounces of alcohol, and allow both bladders to be similarly exposed on a sandbath till all the water has evaporated through the pores of the membrane, which will be accomplished in about four days; and it will then be observed that whilst eight ounces of water have made their exit from the bladder, only one ounce of alcohol has thus evaporated, and seven ounces still remain in the bladder. This experiment explains why smugglers, a few generations ago, could supply a whisky which was stronger, and hence esteemed preferable, as they carried the whisky in bladders around their persons, and the water escaping therefrom in much greater proportion than the alcohol, a stronger spirit was left.

Absolute or anhydrous alcohol has a specific gravity of .793 at the temperature of 60° F. (15.5° C.). It boils at 173° F. (78.4° C.). At a very low temperature alcohol becomes of an oily or greasy consistence, at a still lower temperature it assumes the appearance of melted wax, and at a temperature of -203° F. (-131° C.) it becomes solid. Such low temperatures are obtainable by the application of liquid air.

This property of non-freezing at any degree of cold to which the earth is subjected has led to the employment of alcohol coloured red by cochineal, in the thermometers sent out to the arctic regions. It is highly inflammable, its combustion yielding only carbonic acid and water. It has a very strong attraction for water, and when mixed with it, much heat is evolved and a contraction in volume takes place. Thus 2 gallons of alcohol and 1 of water measure less than 3 gallons. Its poisonous action when taken internally in large quantity has been referred to this same property, the idea being that it removes water from the tissues, and thus destroys them. The formula of alcohol is C_2H_5OH . In 100 pounds, therefore, of alcohol, about 53 are carbon, 13 hydrogen, and 34 oxygen. Besides the alcohol consumed in wine, beer, and spirits, it is much employed in pharmacy and in the arts. It is a powerful solvent for resins and oils; and hence is employed in the preparation of varnishes. In Germany, a cheap spirit made from potatoes is much used for cooking on a small scale.

During recent years, our knowledge of the properties of ordinary alcohol, and of the general class of bodies to which the term ALCOHOLS is applied, in consequence of their resemblance, in certain chemical reactions, to ordinary alcohol, has been very much enlarged. The alcohols are all compounds of carbon, hydrogen, and oxygen, and are perfectly neutral to test-papers. Many of them are produced along with ordinary alcohol in the process of fermentation, and alter the flavour of the resulting beverage; such are amylic (fusel oil) and butylic alcohol. They are chiefly characterised by yielding, on treatment with acids, neutral bodies called ethers, the formation of water being a part of the

reaction. According to the theory of Types (see the article CHEMISTRY), the alcohols are divided into monatomic (comprising the important series of methyl, ethyl, propyl, and other alcohols, which are referred to further below) and polyatomic. According to their behaviour on oxidation, they are further divided into primary, secondary, and tertiary.

In a nearly anhydrous state, alcohol has little tendency to oxidation, but when freely diluted, and exposed to the air, it rapidly becomes oxidised into acetic acid. This conversion is, however, not a direct one, an intermediate compound, termed Aldehyde (q.v.), being first formed, which is rapidly oxidised into acetic acid. The oxidation of alcohol into aldehyde is represented by the equation,

and the further oxidation of aldehyde into acetic acid is represented by

In the first reaction, alcohol loses two atoms of hydrogen, water being formed; in the second, aldehyde takes up one atom of oxygen.

Every alcohol which like ordinary alcohol yields on oxidation an aldehyde, and on further oxidation an acid having the same number of carbon atoms as the alcohol itself, is termed a primary alcohol. To take another example, primary propyl alcohol, $\text{C}_3\text{H}_7\text{OH}$, is oxidised first into propyl aldehyde, $\text{C}_3\text{H}_7\text{OH}$, and then into propionic acid, $\text{HC}_3\text{H}_5\text{O}_2$. Primary alcohols are subdivided into normal and iso-alcohols, but it would lead us too far to explain the meaning of this distinction.

Secondary alcohols on oxidation lose two atoms of hydrogen, and are converted into bodies known as acetones or ketones, which differ from aldehydes inasmuch as they are not converted on oxidation into acids having the same number of carbon atoms, but are split up into acids having a smaller number of carbon atoms. Thus secondary propyl alcohol is oxidised into acetone, and on further oxidation, acetone splits up into formic and acetic acids,

It will be observed that propyl alcohol and secondary propyl alcohol, propyl aldehyde and acetone, are respectively isomeric (see ISOMERISM).

Tertiary alcohols on oxidation give no aldehydes, but split up into ketones and acids having a smaller number of carbon atoms. Thus tertiary butyl alcohol, $(\text{CH}_3)_3\text{COH}$, which is isomeric, with primary and with secondary butyl alcohol, yields acetone and then acetic and formic acids. Only a comparatively small number of secondary and tertiary alcohols are at present known, and their properties and reactions have not been so thoroughly studied as those of the much more numerous class of primary alcohols. Theoretical considerations, however, lead to the belief that their number will be largely increased.

Ordinary or ethyl alcohol is monatomic—i.e. it may be regarded as being derived from the type HOH , by the substitution of its radical ethyl, C_2H_5 , for one atom of hydrogen. This view is expressed by the formula $\text{C}_2\text{H}_5\text{OH}$.

The monatomic alcohols are more abundant than all the polyatomic alcohols put together. There are several series of them, of which the most important are alcohols whose radical is of the formula $\text{C}_n + \text{H}_{2n+1}$ (as methyl, CH_3 ; ethyl, C_2H_5 ;

propyl, C_3H_7 , &c.), and which are represented by the formula $(\text{C}_n\text{H}_{2n+1})\text{HO}$. They are intimately related to the fatty acids, whose general formula is $\text{C}_n\text{H}_{2n}\text{O}_2$, and which may be formed from the alcohols by oxidation, H_2 being replaced by O . The three highest alcohols of this set, cetyllic, ceryllic, and melissylic alcohols, have the formulæ $\text{C}_{16}\text{H}_{33}\text{HO}$, $\text{C}_{27}\text{H}_{55}\text{HO}$, and $\text{C}_{30}\text{H}_{61}\text{HO}$, and are solid, waxy, or fatty matters.

Of the polyatomic alcohols, diatomic alcohols belong to the secondary water type, $(\text{H}_2\text{O})_2$ or H_2O_2 . Thus the most important diatomic alcohol, glycol, $\text{C}_2\text{H}_6\text{O}_2$, is represented, according to the theory of types, by the formula $(\text{C}_2\text{H}_4)''\text{O}_2\text{H}_2$, its radical, C_2H_4 , being marked with two dashes to indicate that it replaces two atoms of hydrogen. So also there are tri-, tetra-, and hexatomic alcohols corresponding to 3, 4, and 6 molecules of water, examples of which are glycerine, $(\text{C}_2\text{H}_5)''' \text{O}_3\text{H}_3$; erythritol (obtained from litmus), $(\text{C}_4\text{H}_8)'''' \text{O}_4\text{H}_4$; and mannitol (from manna), $(\text{C}_6\text{H}_{12})''''' \text{O}_6\text{H}_6$.

Dry chlorine and absolute alcohol react on each other in a singular manner—the final product being a solid compound of alcohol with a very remarkable colourless oily fluid, called chloral, having a peculiar penetrating and irritating odour, and having the formula $\text{C}_2\text{Cl}_3\text{OH}$. By treatment with strong sulphuric acid, this chloral is set free, and may be changed into chloroform by warming with an alkali. Dilute alcohol, distilled with chloride of lime (bleaching-powder), yields chloroform; and this is the most economical process for obtaining this invaluable compound. Heated with an excess of sulphuric acid, alcohol loses all its oxygen in the form of water, and is converted into ethylene, the result being shown by the equation,

A less complete dehydration, under the action of sulphuric acid, converts alcohol into ether. The process is a complicated one, but the final result is expressed by the equation,

The best tests for discovering the presence of alcohol are—(1) Its hot pungent taste, its odour, and its great volatility. (2) Absorbed in asbestos, it burns with a pale blue flame, which deposits no carbon on white porcelain; and when burned in the mouth of an inverted test-tube, containing a few drops of solution of baryta, it produces a well-marked deposit of carbonate of baryta—carbonic acid and water being the products of its combustion. (3) When boiled with sulphuric acid, and a few drops of a saturated solution of bichromate of potash, it reduces this salt to green sulphate of chromium. The chromium test, originally discovered by Dr Thomson in 1846, is that on which the French physiologists Lallemand, Perrin, and Duroy relied in their investigations regarding the presence of alcohol in the blood, urine, expired air, &c. (4) The least trace of alcohol in an aqueous solution can be detected by adding a little chloride of benzoyl, and then a little caustic potash; benzoate of ethyl, a liquid having a very characteristic aromatic odour, is at once formed, and enables one thousandth part of alcohol in a teaspoonful of water to be detected.

Alcohol is of a double use to the chemist, inasmuch as it furnishes a cleanly and valuable fuel when used in the spirit-lamp, and possesses remarkable solvent powers without in general exerting chemical action on the dissolved substances. It dissolves many of the gases more freely than water, as, for example, nitrous oxide, carbonic acid, phosphuretted hydrogen, cyanogen, and the hydro-carbons, as, for instance, ethylene. Amongst the

mineral substances which it dissolves may be mentioned iodine, bromine, boracic acid, the hydrates of potash and soda, the chlorides of calcium, strontium, magnesium, zinc, platinum, and gold, the perchloride of iron, corrosive sublimate, the nitrates of lime, magnesia, &c.; whilst amongst organic matters, it dissolves many organic acids, bases, and neutral bodies, the resins, the soaps, and the fats. The latter dissolve more freely in ether than in alcohol. The alcoholic solutions of substances used in medicine are called *Essences, spirits, and tinctures*. See BRANDY, WHISKY, FUSEL OIL, AMYL.

ACTIONS AND USES OF ALCOHOL.—Alcohol, or, more correctly, ethyl alcohol (C_2H_5O), is extensively used as a beverage by man in many different nations. In Europe it is generally consumed as (a) beer, formed by alcoholic fermentation of barley; (b) whisky, produced by fermentation of various grains; and (c) brandy and wines, produced by fermentation of grape-juice. The effects produced by these are due to the alcohol they contain.

The action of alcohol may be considered (1) while it is still in the stomach; (2) after it is absorbed from the stomach. Alcohol in moderate doses, when taken with meals, has practically no action upon digestion or the absorption of food, but when taken apart from food, and especially when not markedly diluted, it produces a dilatation of the blood-vessels of the stomach, and may set up a chronic congestion. This was first observed by Dr Beaumont in the case of a backwoodsman, St Martin, who, as a result of a gunshot wound, had a hole into his stomach, through which it was possible to study the lining membrane. Alcohol is absorbed without undergoing any change. The absorption is at first very rapid, but later becomes slower, apparently as a result of the alcohol exercising a poisoning action on the lining membrane of the stomach. When absorbed it is rapidly oxidised, and liberates energy in the same way as do sugars and fats. Its energy value is intermediate between those of sugar and fats, being 7 calories per gram; i.e. the oxidation of 1 gram of alcohol in the body, just as its burning outside the body, yields enough energy, as heat, to raise the temperature of 1 kilogram of water through 7° C. But while sugars and fats are oxidised to an almost unlimited extent, and when not immediately oxidised are largely stored in the body, alcohol can be combusted only to a limited extent, and even in moderate doses it may be present in the blood many hours after it has been administered. It cannot be stored for future use as fats, sugars, and starches are stored. Most people can fully oxidise about 2 oz. in the twenty-four hours. But the power of doing so varies in different people and in the same person at different times. Hence its value as a source of energy is limited. All alcohol in the body before it is oxidised, and if it escapes oxidation, acts as a drug. It stimulates and quickens the heart. It dilates the blood-vessels, especially those of the skin, and thus, in spite of the increased action of the heart, the pressure of blood in the arteries is not raised. By dilating the vessels of the skin it allows more of the warm blood from the central parts of the body to come to the surface, and so produces a sensation of warmth. But the blood is thus rapidly cooled and the temperature of the body falls, and, in exposure to cold, alcohol is prejudicial. On the nervous system it acts as a poison in the same way as do ether and chloroform, and like these drugs it first affects the higher centres of the brain. Hence the critical faculties and the power of judgment are interfered with, and the individual misjudging his own cerebral activity may feel convinced that it is working better than usual. But the application of such tests as doing rapid calculations shows that this is an error, and

that the power of mental work is decreased. Later the perception of sensation is blunted, and in this way the sense of fatigue may be removed. The poisoning gradually extends to the lower centres, and the motor powers of speech and locomotion are finally involved. It is this action of alcohol on the nervous system which so markedly limits its uses as a food. A man may liberate the energy from the alcohol he takes, but, long before any manifest symptoms are produced, his power of judgment and his power of directing the finer actions of his muscles are so interfered with that he is unable to make full use of the energy, not only of that liberated from the alcohol, but also of that liberated from the carbohydrates, fats, and proteins of his food, and thus his working efficiency is decreased. Alcohol may, and does, increase the pleasure of life by paralysing the critical faculty, and it brings comfort to the weary by removing the power of appreciating the sense of fatigue. In fact, its great use is in extreme fatigue, not when more work has to be done, but when the work is over. Then it acts as a stimulant to the heart, to a limited extent as a rapidly available source of energy and as a paralyrant to the sense of fatigue. In fever it is sometimes useful in increasing the loss of heat, and thus lowering the temperature. To the normal healthy man it is at best a somewhat dangerous luxury. The uses of alcohol in thermometers and spirit-lamps and as a solvent have been mentioned above. It is also employed as a source of power.

Alcoholism. While formerly the abuse of alcohol was universally regarded either as a vice or a disease, within recent years the view that it constitutes a form of response to a psychological necessity has been strongly advocated. As one of the many exponents of this view has expressed it, 'in the tragic conflict between what he has been taught to desire and what he is allowed to get, man has found in alcohol, as he has found in certain other drugs, a sinister but effective peace-maker, a means of securing, for however short a time, some way out of the prison-house of reality back to the Golden Age.'

According to the theory of Freud and his disciples, mental health depends on a state of equilibrium between instinctive tendencies and the forces by which they are controlled. A failure in this equilibrium entails a more or less painful conflict between the opposing forces, which in normal individuals may be solved by the suppression of the undesirable element, or by seeking adjustment in healthy activities. In subnormal or neurotic individuals, the conflict may result in some form of the neuroses or psychoses, or by escape from its pressure by resort to such a subterfuge as alcohol. The immediate success which follows its use is due to the lessening of the anxiety caused by the conflict. The failure of the expedient to permanently solve the conflict is due to the injurious effect of alcohol upon the higher controlling mental processes, which tends to strengthen the instinctive side of the forces responsible for the conflict, and to the formation of a habit which in its most characteristic form is known as Dipsomania (q.v.).

Tolerance to alcohol varies greatly in different individuals. Some persons are so tolerant that they can go on drinking steadily for years without manifesting any very obvious psychical or physical disturbances. Others, on the other hand, are so intolerant to its use that comparatively small quantities may produce dangerous bodily or mental consequences. In view of that fact, we are bound to assume that persons who develop any of the forms of alcoholism are constitutionally psychopathic.

The symptoms of disease produced by alcoholic

poisoning may be considered under two heads, according as the affection is acute or chronic.

Acute Alcoholism, which is generally caused by the rapid absorption of a large quantity of alcohol, commonly begins with the same train of symptoms—animation of manner, exaltation of spirits, and relaxation of judgment, which lead to want of mental control. The emotions are always altered, and often perverted. The co-ordination of muscular movements is impaired, and they become irregular or ataxic in character. The mechanism of speech is, as a rule, the first to suffer, but other muscular efforts are also rendered imperfect, the erect posture even becoming impossible. Thus far, the initial manifestations are tolerably uniform, but the further development of the symptoms presents three different series of effects. In the ordinary course of the action of the drug, the individual suffers from headache, giddiness, disturbance of sight and hearing, and other troubles due to disorder of the central nervous system, which lead to heavy sleep or profound coma. Usually the individual may be roused from the sleep or coma, but when this is very deep it may be impossible to do so, and he lies completely paralysed, breathing stertorously. Sometimes the alcohol produces such a powerful effect upon the centres of respiration and circulation that death is caused by paralysis of one or other, or both. This condition of coma requires to be carefully distinguished from opium poisoning. In the former, the face is usually flushed and the pupils dilated, while in the latter the face is pale and the pupils contracted; but these appearances are not constant; and it need hardly be added that the odour of the breath is no criterion, inasmuch as the use of spirits is regarded as the panacea in all conditions of depression, and sympathising bystanders are prompt to administer them in every case, often with very hurtful effects. The second class of effects is entirely different from the foregoing. Instead of sinking into sopor or coma, the individual under the influence of the poison becomes more and more excited, bursts into wild mirth or passionate anger, engages in violent struggles with any one who attempts to soothe him, and may do grievous bodily harm to himself or others. This is the condition known as alcoholic mania, and it is the physical explanation of many fearful crimes. After a longer or shorter period of fierce excitement, it is in most cases succeeded by great depression, and sometimes during this condition there may be sudden death from failure of the respiration or circulation. In the third division, the stage of excitement culminates in a convulsive seizure somewhat resembling that seen in hystero-epilepsy. The convulsions, which are repeated at intervals, are very complicated in their character, and produce remarkable contortions of the body. These usually become less violent as they recur, and passing off, end in deep sleep; but here also death may occur from the action of the poison. It should be observed that acute alcoholism is more apt to occur in those who are of unsound mind and weak nervous system, and this applies especially to the two last-described forms of the affection. In the treatment of acute alcoholism, it is sometimes necessary to wash out the stomach in case any alcohol may be present, but from its rapid absorption this is rarely the case. In the profound coma the administration of stimulants, such as ammonia, may be called for, and sometimes artificial respiration may be the only means of saving life. In the maniacal and convulsive forms of the affection, chloral along with bromide of potassium must be used. After the immediate symptoms have passed away in all forms, the individual must be carefully fed, on

account of the disturbance of the digestive system which is caused by the overdose of alcohol, with nutrient enemata, along with remedies which will subdue the digestive irritation and stimulate the depression of the nervous system.

Chronic Alcoholism is caused by the prolonged use of overdoses of various alcoholic drinks. The drug causes changes in every tissue of the body, but it more especially affects the nervous, respiratory, and circulatory systems, together with the liver and kidneys. There is always more or less catarrh of the digestive organs, shown by dyspepsia, heartburn, flatulence, nausea, vomiting—especially in the morning—and usually diarrhoea. The liver, to which, in the first instance, all the alcohol absorbed is carried by the vessels, becomes enlarged from congestion in the early stages; and it afterwards shrinks, from the development of fibrous tissue by chronic irritation and the subsequent contraction of this new growth; it exercises pressure on the veins bringing back blood to the heart from the abdominal viscera—thus leading to congestion of the bowels, hemorrhoids, and hemorrhages. In some cases there is fatty degeneration of the liver, with or without the fibrous change. From changes in the organs of circulation, there is a tendency to palpitation, fainting, and breathlessness on exertion. These alterations are degenerations of the heart, which may be soft and flabby, or even fatty; fibrous changes in the walls of the arteries; and dilatation of the capillaries from paralysis of the vaso-motor nerves. This last condition gives the florid complexion and mottled appearance to chronic drinkers, and it renders them prone to all inflammations, which, as may be expected, are much more fatal to them than to temperate men. Connected with these changes in the circulation, there is usually some congestion of the kidneys; but it is erroneous to attribute Bright's Disease mainly to alcohol. The lungs are subject to chronic congestion and catarrh of the bronchial tubes and lung-tissues. The muscular system suffers, the muscles becoming flabby and fatty. There is a great tendency to deposition of fat, from interference with digestion, and skin-diseases are frequently induced by the vaso-motor changes.

But of all the symptoms of chronic alcoholism those connected with the nervous system are the most characteristic. The moral sense is impaired, the will-power weakened, and the intellectual energies enfeebled, but there are in addition two characteristic results of the poisonous action of the drug upon the central nervous structures. These are delirium tremens and alcoholic insanity. The former consists in a delirium, varying from quiet wandering to wild mania, marked by hallucinations, usually of a revolting character, such as of creeping reptiles, with tremulousness of the muscles, attended by sleeplessness: the latter may assume many of the clinical aspects of insanity. After death, the morbid anatomy consists in congestion of the membranes of the brain, which are more adherent to the skull and brain than in health; there is usually opacity of the middle or arachnoid membrane, and an increase in the cerebro-spinal fluid. The brain and spinal cord show no definite alterations. The peripheral nervous system also suffers, and there may be pain and tenderness, or loss of sensibility, and tremor, spasm, or paralysis in various areas, according as the sensory or motor nerves are affected. The appearances after death are those of neuritis, or inflammation of the nerves supplying the affected regions. In the treatment of chronic alcoholism, the great point is to put a stop to the employment of alcohol in every form, and this usually requires careful moral discipline. The bodily and mental functions must be invigorated by all means, and an outdoor life is one

of the best. In delirium tremens the patient must have sleep, which may be induced by bromide of potassium and chloral hydrate.

See also the articles on DELIRIUM TREMENS, DIPSO-MANIA, INEBRIATES (Retreats for), TEMPERANCE, INSANITY (for alcoholic insanity), SPECIFIC DENSITY (for alcoholometry).—The researches of Miss Elderton at the Galton Laboratory (1910), assisted by Professor Karl Pearson, point to the surprising but comforting conclusion that parental alcoholism has little or no appreciable influence for evil on the physique or intelligence of the offspring, or on its liability to diseases.

Al'coran. See KORAN.

Alcott, LOUISA MAY, a popular American writer, daughter of Amos Bionson Alcott, a noted educationist, was born at Germantown, Pennsylvania, November 29, 1832, was for some years a teacher, and published her *Flower Fables* in 1855. Her life as a volunteer hospital nurse during the civil war furnished material for her *Hospital Sketches* (1865), and supplied a background for several of her tales. She had written for the *Atlantic Monthly*, and published several books before her first and greatest success, *Little Women* (1868), and a second part (1869), which was followed by *Little Men* (1871), with its sequel, *Jo's Boys* (1886). Amongst her numerous other works are *An Old-fashioned Girl* (1869); *Under the Lilacs* (1878); *An Old-fashioned Thanksgiving* (1882); *Proverb Stories* (1882); *Spinning-wheel Stories* (1884); *Lulu's Library* (1885). She died 6th March 1888—two days after her father, AMOS, who was born 29th November (also) 1799. The father, originally a pedlar, became distinguished as a reformer of education and a remarkably successful disciplinarian, his method being of the gentlest. In other respects, though his friend and spiritual master, Emerson, said he had 'singular gifts for awakening contemplation and aspiration in simple and in cultivated persons,' he was a somewhat helpless idealist and transcendentalist. He wrote much for the *Dial*, and published *Conversations with Children on the Gospels* (1837); *Spiritual Culture* (1841); *Table-Talk* (1877); *Sonnets and Canzonets* (1882). See his *Life and Philosophy*, by Sanborn and Harris (1893); and Louisa's *Life, Letters, and Journals*, by Cheney (1889).

Alcoy, a manufacturing town of Spain, on the river Alcoy, 15 miles N. of the town of Alicante. It is 'built in a funnel of the hills, on a tongue of land hemmed in by two streams, with bridges and arched viaducts.' The staple manufacture is paper, especially cigarette-paper. Pop, 34,000.

Alcudia, MANUEL DE GODOY, DUKE OF, a Spanish statesman, was born at Badajoz, 12th May 1767. A mere boy when he came to court, his handsome figure and agreeable manners soon gained him the favour of the queen and of the weak king, Charles IV. He was successively made Duke of Alcudia (taking his title from a small town of that name in Majorca), generalissimo of the forces, and prime minister in 1792. He received the title of 'Prince of the Peace' for his share in the treaty with France, concluded at Basel in 1795. His power, which was at its height in 1807, from that time began to decline. The nobles hated him for his monopoly of political power, while the people ascribed to his ambitious prodigality all the poverty and misery that was the consequence of a long war. When the king abdicated in favour of his son in 1808, Alcudia's life was only saved by the promise of a trial. This trial, however, never took place. Napoleon, who knew his influence over the mind of the Spanish king, had him liberated, and brought to Bayonne, where he instigated all measures taken by the ex-king and queen. After the death of Charles IV. he lived at Paris, and received a small

pension from Louis-Philippe. In 1847 his return to Spain was permitted, and his titles, together with great part of his wealth, restored. He died at Paris, 7th October 1851. His *Memoirs* were published (8 vols.) in 1836, and a life of him by D'Auvergne (*Godoy, the Queen's Favourite*) in 1912.

Alcuin (*Ealwune* or *Albinus*), the adviser of Charlemagne, and a renowned scholar, was born at York about 735, and educated at the cloister school of York, under the care of Archbishop Egbert and Ethelbert, and succeeded the latter as master of the school in 778. Three years later, on his return journey from Rome with the *pallium* of the new Archbishop of York, he met Charlemagne at Parma; and the year after he yielded to the invitation of the monarch, and took up his residence at his court at Aix-la-Chapelle. Here he devoted himself first to the education of the royal family itself, and through his influence the court became a school of culture for the hitherto almost barbarous Frankish empire. Even the great emperor himself sometimes took his place as a pupil in the school, and he gave his master the revenues of three abbeys for his support. In 790 Alcuin was sent to England to renew the peace with King Offa of Mercia. Two years later he returned, and soon afterwards became involved in the controversy against the Adoptian heresy. In 796 he retired from the court, and settled at Tours, of which he had been made abbot. The school here soon became, under his fostering care, one of the most important in the empire, and the nursery for other schools elsewhere. While living at Tours, he corresponded constantly with Charlemagne. He died here in 804. Alcuin is more famous for the influence he exerted than for any work he gave to the world himself. His writings have but little profundity, nor, indeed, have his Latin poems much artistic merit; but he gave a powerful stimulus to Western learning, and occupies a conspicuous place in the history of letters as the apostle of culture and urbanity in a rude and indeed almost barbarous age. His prose writings mainly consist of elementary scholastic works on grammar, rhetoric, and dialectics; theological works, including biblical commentaries, and treatises on the dogma of the Trinity, and on practical morals; lives of several saints—one, Saint Willibrord, especially interesting to Englishmen; and over two hundred letters to Charlemagne, to friends in England, and to Arnulf of Salzburg, his friend and pupil. The best edition of his works is by Frobenius (Ratisbon, 1777). It has been reprinted in Migne's great *Patrologæ Cursus*, edited by Angelo Mai (1851). See *Life* by Lorenz (1829); *Monnier's Alcuin et Charlemagne* (1864); *Mullinger's Schools of Charles the Great* (1877); *Werner's Alkuin und sein Jahrhundert* (1881); A. F. West's *Alcuin* (1893); and Gaskoin's *Alcuin, his Life and Work* (1904).

Alcyonaria, one of the two orders of Actinozoa (q.v.), including polyps, with eight tentacles and radial partitions. They usually form colonies, and have always some kind of skeleton. Dead-men's fingers, sea-pens, red corals, and organ-pipe corals, are common representatives of the order.

Alcyonium, or DEAD-MEN'S FINGERS, an exceedingly common coelenterate of the sub-class Actinozoa, belonging to the same order (Alcyonaria) as the sea-pen, the red coral, the organ-pipe coral, &c. It is often found on the coast, in somewhat deep water, as an irregularly lobed mass of a white, creamy, or orange colour, attached to stones and shells. The whole varied clump, which is frequently about the size of a man's hand, whence the popular name, is not one animal, but a myriad colony. When undisturbed, the countless individual polyps may be seen projecting from

the surface like miniature sea-anemones, about the size of a snail's horns (fig. 1). Each polyp consists of

Fig. 1.

A stock of *Alcyonium*, showing individual polyps.
(After Johnston)

a contractile tube, with a crown of tentacles round a slit-like mouth, and with the margin of the latter

Fig. 2.

Longitudinal section of a single polyp at maximum extension, showing pinnate tentacle round mouth, neck region, protruded stomach tube (*d*), and lower gastral region with suggestion of mesenteries (*e*).
(Vogt and Yung)

Fig. 3.

Cross section at level of mesenteries (from Vogt and Yung, after Hartwig), showing the body wall with its three layers, the radial mesenteries (*d*) with intervening chambers, and the central much narrowed stomach tube (*e*)

prolonged inwards to form an inner stomach tube, connected with the outer wall by radial partitions or mesenteries (fig. 2). So far the general structure is that of a sea-anemone, but in all *Alcyonaria*, and in *Alcyonium* among the rest, there are eight, and not six, tentacles and mesenteries. As in other *Alcyonarians*, the tentacles are pinnate, and bear very minute stinging cells. The eight mesenteries bear eight filaments, two respiratory and six digestive. The food consists of minute organisms and organic particles. Between the cavities of the polyps which compose the colony there is a gelatinous matrix or coenenchyma, traversed by canals which connect polyp with polyp. As in all *Alcyonarians*, the buds, which are con-

tinually being formed as the colony grows, arise not directly from the polyps, but from the canals given off by the polyps. In the polyps and in the whole colony there are abundant irregularly shaped calcareous spicules which remain isolated from one another. The genus *Alcyonium* is widely distributed in temperate and cold waters, usually at no great depth. The common British species is *Alcyonium digitatum*. There are two other compound animals with somewhat similar names, *Alcyonidium* and *Alcyonella*, which used also to be ranked as zoophytes, but are now known to belong to the widely separated class of *Polyzoa* (q.v.). See *ALCYONARIA*, *CELENTERATA*, *SEA-ANEMONE*, *ZOOPHYTE*, &c., and '*Alcyonium*' by Professor S. J. Hickson in the *Liverpool Biological Memoirs*.

Fig. 4.

Small Portion of a Colony.

Aldabra, an atoll enclosing a lagoon and cut by channels into four islands, constituting a dependency of the Seychelles, from which it lies nearly 700 miles to the SW. The atoll is about 40 miles in circumference, and a mile and a half in breadth; the land area is about 60 sq. m., and the pop. 130. The rugged coral rock is thickly covered with scrub, mangroves lining the lagoon. The fauna and flora are partly peculiar, partly common to these islands with Madagascar, the Mascarenes, and the Comoro Islands. Aldabra was known to the Arabs by this name ere the Portuguese visited it in 1511, and fell to Britain with the Seychelles in 1810.

Aldbrough, a decayed town, now a mere village, of the West Riding of Yorkshire, on the river Ure and on Watling Street, $7\frac{1}{2}$ miles SE. of Ripon. Till 1832 it sent two members to parliament. Extensive remains of the Roman town of Isurium have been found here. Pop. 400. See also **ALDEBURGH**.

Aldebaran, the Arabic name of a star of the first magnitude in the constellation Taurus. It is the largest and most brilliant of a cluster of five which the Greeks called the Hyades. From its position it is sometimes termed 'the Bull's Eye.'

Aldeburgh, a small seaport and watering-place on the coast of Suffolk, 29 miles NE. of Ipswich by rail. A parliamentary borough since 1572, it was disfranchised in 1832; but in 1885 it received a new municipal charter. It has a quaint, half-timbered Moot Hall; and in the church is a bust of George Crabbe, who was a native, and who delineates the character of the place and its people in his poems. Dr Gaillett Anderson, mayor of Aldeburgh in 1908, was the first woman to become mayor of any English borough. Pop. 3000.

Aldegonde. See **MARNIX**.

Aldegrever, or **ALDEGRAF**, properly **TRIPPEN-MAKER**, **HEINRICH** (1602-58), a Westphalian engraver and painter, born at Paderborn, lived at Soest. He was a follower of Albrecht Dürer.

Aldehyde, CH_3COH , is a volatile fluid produced by the oxidation and destructive distillation of alcohol and other organic compounds. There are many modes of obtaining it; the following is the method described by Liebig: A mixture of 2 lb. of strong alcohol, 3 lb. of manganese dioxide, 2 lb. of water, and 3 lb. of sulphuric acid is distilled into a receiver kept cool by ice. As soon as the distillate reddens litmus-paper, the operation is stopped. The product in the receiver, weighing about 3 lb.,

is then twice rectified over chloride of calcium, being reduced by these operations to about 12 oz. This is then mixed with twice its volume of ether, and saturated with ammonia gas. After cooling, crystals of aldehyde ammonia, $C_2H_4ONH_3$, are formed, which are mixed with dilute sulphuric acid, and distilled at a low temperature. The hydrated aldehyde thus obtained is dried with chloride of calcium and again rectified by distillation. Aldehyde is a thin, transparent, colourless liquid, very inflammable, burning with a blue flame, and having a spec. gr. of '800, a boiling-point of about $70^\circ F.$ ($21^\circ C.$), a melting-point of $-286^\circ F.$ ($-121^\circ C.$), and a pungent, suffocating odour. It mixes in all proportions with water, alcohol, and ether, and dissolves sulphur, phosphorus, and iodine. As is shown in the article ALCOHOL, it constitutes an intermediate stage in the oxidation of alcohol into acetic acid. When potassium is gently heated with aldehyde, one atom of H is replaced by one of K, the resulting compound being aldehyde of potash, CH_3COK . Various compounds of this kind may be formed, of which the most important is aldehyde of ammonia, or aldehyde-ammonia, $C_2H_4ONH_3$, which is obtained in transparent shining crystals, and is a compound that has led chemists to the discovery of a large number of very remarkable derivatives.

ALDEHYDES are a class of organic compounds intermediate between primary alcohols and acids. Each aldehyde is derived from the corresponding alcohol by the abstraction of two atoms of hydrogen, and each aldehyde is converted into its corresponding acid by the addition of one atom of oxygen.

Ten aldehydes of the series $C_nH_{2n}O$, corresponding to $n = 1, 2, 3, 4, 5, 7, 8, 11, 12$, and 16, are at present known, the simplest being formic aldehyde, CH_2O , and the highest being palmitic aldehyde, $C_{16}H_{32}O$.

Amongst aldehydes not connected with the preceding group may be mentioned various organic compounds which have been recently shown to belong to this class—thus, acrolein, C_3H_4O , is acrylic aldehyde; camphor, $C_{10}H_{16}O$, is campholic aldehyde; bitter-almond oil, C_7H_6O , is benzoic aldehyde; oil of cumin, $C_{10}H_{12}O$, is cuminic aldehyde; oil of cinnamon, C_9H_8O , is cinnamic aldehyde. Most of these aldehydes are obtained directly from plants, and either exist in them ready formed, or are given off as volatile oils on distillation with water. Owing to their great tendency to oxidise into their corresponding acids, the aldehydes are powerful reducing agents. They reduce the silver in silver salts to the metallic state. On the other hand, by the action of nascent hydrogen upon the aldehydes, the corresponding alcohols are regenerated. Thus ordinary alcohol may be obtained from ordinary aldehyde.

Acetic Aldehyde.

Ethyl Alcohol

With the acid sulphites of the alkalies the aldehydes form sparingly soluble crystalline compounds. When treated with caustic alkali, many of the aldehydes are converted into the corresponding alcohols, and the potassium salt of the corresponding acid. Thus benzoic aldehyde yields benzyl alcohol and benzoate of potash:

The aldehydes have a great tendency to form polymeric compounds. Thus ordinary aldehyde passes readily into two polymeric modifications (see ISOMERISM): (1) Par-aldehyde, a liquid which boils at $255^\circ F.$ ($124^\circ C.$); (2) Metaldehyde, a solid body which sublimes at $239^\circ F.$ ($115^\circ C.$), and is converted back into ordinary aldehyde by heating to $248^\circ F.$ ($120^\circ C.$) for a few hours in a closed vessel.

Alder (*Alnus*), a genus of plants of the *Betulaceae* tribe (see also BIRCH), of the natural order *Betulaceae* (see also HAZEL, HORNBEAM). This genus consists entirely of trees and shrubs, natives of cold and temperate climates; the flowers in terminal, imbricated catkins, which appear before the leaves; the male and female flowers in separate catkins on the same plant; fruit, a compressed nut without wings.—The COMMON or BLACK ALDER (*A. glutinosa*) is a native of Britain, and

Common Alder (*Alnus glutinosa*).

of the northern parts of Asia and America. It has roundish, wedge-shaped obtuse leaves, lobed at the margin and serrated. The bark, except in very young trees, is nearly black. It succeeds best in moist soils, and helps to secure swampy river-banks against the effects of floods. It attains a height of 30 to 60 feet. Its leaves are somewhat glutinous. The wood is of an orange-yellow colour, not very good for fuel, but affording one of the best kinds of charcoal for the manufacture of gunpowder, and hence was formerly often grown as coppice-wood. Great numbers of small trees were also used in Scotland for making staves for herring-barrels. The wood is employed by turners and joiners; but it is particularly valuable on account of its property of remaining for a long time under water without decay, and is therefore used for the piles of bridges, for pumps, sluices, pipes, cogs of mill-wheels, and similar purposes. The bark when used for tanning produces a yellow or red colour, or with copperas a black colour. The leaves and female catkins are employed in the same way by the tanners and dyers of some countries. The bark is bitter and astringent, and has been used for gargles, and also administered with success in ague. The seeds are a favourite food of greenfinches. In boggy grounds the alder is often almost the only kind of tree, and in many parts of the Highlands groups of alders and of birch are scattered over the lower parts of the mountain slopes.

There are several handsome varieties of the common alder employed in ornamental planting, the most distinct being the GOLDEN ALDER, the leaves of which are bright golden yellow; and the CUT-LEAVED ALDER, with narrow, deeply incised leaves, and a much more graceful habit than the common form. The common alder ceases on the Swedish shore on the lower part of the Gulf of Bothnia.—The GRAY or WHITE ALDER (*A. incana*), a native of many parts of continental Europe, especially of the Alps, and also of North America and of Kamchatka, but not of Britain, differs from the common alder in having acute leaves, downy beneath, and not glutinous, a gray bark, in throwing up many root-suckers, and in producing more and larger nodules on

the roots. The wood is white, fine-grained, and compact, but readily rots under water. The bark is used in dyeing.—*A. cordifolia* is a large and handsome tree, with cordate acuminate leaves, a native of the south of Italy, but found to be quite hardy in England. Some of the American species are mere shrubs. Several species are natives of the Himalayas.—The BERRY-BEARING ALDER, or BREAKING BUCKTHORN, is a totally different plant (see BUCKTHORN).

Alderman, a title derived from the Anglo-Saxon *ealdorman*, compounded of *ealdor* ('older') and *man*. Whether any definite and invariable functions were connected with the ancient rank of *ealdorman* does not seem to be very clearly ascertained. The term was generally applied to persons of high and hereditary distinction, such as princes, earls, and governors. Its special signification in the titles 'Alderman of all England' (*Aldermannus totius Angliæ*) and 'King's Alderman' (*Aldermanus Regis*) is not distinctly indicated. There were also aldermen of counties, hundreds, cities, boroughs, and castles. In modern times, aldermen are officers invested with certain powers in the municipal corporations and counties of England, Wales, and Ireland, either as civil magistrates, or as assessors of the chief magistrates in cities and towns corporate. The title in Scotland is Bailie. The London Court of Aldermen consists of twenty-six aldermen, including the Lord Mayor. The name is now given to the superior county councillors, elected by the councillors, under the Local Government Act of 1888. Women are eligible.

Alderney (Fr. *Aurigny*, Lat. *Riduna*), a British island in the English Channel, 55 miles S. by E. of Portland Bill, 15 N.E. of Guernsey, 31 N. of Jersey, and 8½ W. of Cape la Hague. The Race of Alderney, or strait that separates it from the coast of Normandy, is very dangerous in stormy weather. The length of the island is under 4 miles; its extreme breadth, 1½ mile; its area is 1962 acres, or 3 sq. m. The highest point is 281 feet above sea-level. To the S. the coast is bold and lofty; to the N. it descends, forming numerous bays, one of which (Braye) has been formed into a fortified harbour, with a granite breakwater. The scheme proved ill-advised, and after costing about £2,000,000, was suspended in 1871. The Casquets (Casquets) are a small cluster of dangerous rocks, 6½ miles to the W., on which is a large lighthouse. The soil in the centre of the island is highly productive; and the Alderney cattle (see CATTLE), a small but handsome breed, are celebrated. Agriculture and granite-quarrying are the chief industries. The climate is very sunny and yet bracing. The population was originally French, but thanks to the English garrison and English labourers, English is more generally spoken than in Jersey or Guernsey. Alderney has its own militia. Protestantism has prevailed since the Reformation. Alderney forms part of the bailiwick of Guernsey. The civil power is vested in a judge appointed by the crown, and six *jurats* chosen by the people. These, with twelve popular representatives or *douzeniers* (who do not vote), constitute the local legislature. The 'town' of St Anne is situated in a picturesque valley near the centre of the island; it has a cruciform church (1850) in the Early English style, with a tower 104 feet high. The population of the island is about 3000. See CHANNEL ISLANDS.

Aldershot Camp, a permanent camp of exercise on the confines of Hampshire, Surrey, and Berkshire, 35 miles SW. of London, and 18 S. of Windsor. It was established in 1854-55, during the Crimean War, to provide for practical instruction in tactics, outpost duties, and other exercises requiring a wide tract of country and large bodies

of troops, for which no opportunity had previously been given to the British army, except at the temporary camp of Chobham in 1853. The first purchase of land by government was of about 3 square miles, and this area has been greatly increased by subsequent purchases, the total extent of camping and manœuvring ground being now no less than 30½ square miles. The camp has excellent railway communications N., S., E., and W., with direct lines to London, Southampton, Portsmouth, Sandhurst (where are the Royal Military College and the Staff College), and Salisbury, to N. of which the government have another very extensive manœuvring area on Salisbury Plain. Many millions have been spent on accommodation for the troops, including barracks, stores, and ranges, from the huts of the Crimea days to the fine permanent barracks of modern times. These include all the accessories requisite for a military station, which is at once the largest of its kind in the country and also the chief centre of practical military training on a large scale. The camp is therefore the headquarters not only of tactical combined training for combatant troops, cavalry, artillery, infantry, mounted infantry, engineers, but for administrative training of Army Service Corps, Supply and Transport, Ordnance Store, Royal Army Medical Corps. It also contains the signalling, cookery, balloon, mounted infantry, veterinary, medical, sanitation, and gymnastic schools for the army, and has a riding establishment for the training of officers of regulars and yeomanry. Suitable accommodation has been provided for the sovereign's use when he visits the camp to review the troops. The camp is divided into North Camp and South Camp by the Basingstoke Canal. Aldershot is the first of the seven 'commands' into which the British Isles have been divided, and is presided over by a general officer commanding-in-chief, who commands a cavalry brigade and two complete divisions of the expeditionary force, as well as the other troops collected in the command. The average military population (soldiers) amounts to 26,000, and this is greatly augmented during the summer and autumn, when large bodies of Territorials, yeomanry, and officers' training corps visit Aldershot for their annual fortnight in camp. A considerable town has sprung up near the camp. The borough, created in 1921 (in Hants), has a population of 29,000, as against 875 in Aldershot parish in 1851.

Small similar camps exist at the Curragh of Kildare in Ireland, at Shorncliffe near Dover, at Tidworth and Bulford on Salisbury Plain, the last for artillery; but that at Aldershot is at the same time the largest and most complete garrison in the United Kingdom, and the headquarters of practical military work in the field.

Aldhelm, or EALDHELM, ST, born about 640, was educated at Malmesbury and Canterbury, and became abbot of Malmesbury about 673, Bishop of Sherborne in 705. He died in 709. A skilled architect, he built a little church at Bradford-on-Avon in Wiltshire, identified by some with a building still standing, which others believe to be its successor, built in the 10th century. A great scholar, he wrote Latin treatises, letters, and verses, including riddles, besides English poems that have perished. His extant works are published in Dr Giles's *Patres Eccles. Angl.* (Oxford, 1844). See Lives by Bishop Browne (1903) and W. B. Wildman (1905).

Aldine Editions, the name given to the works that issued (1490-1597) from the press of Aldo Manuzio and his family in Venice. Recommended by their intrinsic value, as well as by their handsome exterior, they have been highly prized by the learned and by book-collectors. Many of them are the first editions (*editiones principes*) of Greek and

Roman classics; others contain corrected texts of modern classic writers, as of Petrarch, Dante, or Boccaccio, carefully collated with the MSS. All of them are distinguished for the remarkable correctness of the typography; the Greek works, however, being in this respect somewhat inferior to the Latin and Italian. The editions published by Aldo Manuzio (1450-1515), the father, form an epoch in the annals of printing, as they contributed in no ordinary measure to the perfecting of types. No one had ever before used such beautiful Greek types, of which he got nine different kinds made, and of Latin as many as fourteen. It is to him, or rather to the engraver, Francesco of Bologna, that we owe the types called by the Italians *Corsivi*, and known to us as Italics, which he used for the first time in the 8vo edition of ancient and modern classics, commencing with Virgil (1501). Manuzio's impressions on parchment are exceedingly beautiful; he was the first printer who introduced the custom of taking some impressions on finer or stronger paper than the rest of the edition—the first example of this being afforded in the *Epistolæ Græcæ* (1499). From 1515 to 1533 the business was carried on by his father and brothers-in-law, Andrea Torressano of Asola, and his two sons—the three 'Asolani.' Paolo Manuzio (1512-74), Aldo's son, possessed an enthusiasm for Latin classics equal to that of his father for Greek; and he was succeeded by his son, the younger Aldo (1547-97). The printing establishment founded by Aldo continued in active operation for 100 years, and during this time printed 908 different works. The distinguishing mark is an anchor, entwined by a dolphin, with the motto either of *Festina lente* or of *Sudavit et alsit*. The demand which arose for editions from this office, and especially for the earlier ones, induced the printers of Lyons and Florence, about 1502, to begin the system of issuing counterfeit Aldines. The Aldo-mania has considerably diminished in later times. Among the Aldine works which have now become very rare, may be mentioned the *Horæ Beatæ Mariæ Virginis* of 1497, the *Virgil* of 1501, and the *Rhetores Græci*; not to mention all the editions, dated and undated, from 1490 to 1497, now extremely rare. See Renouard's *Annales de l'imprimerie des Aldes* (1834), Didot's *Aldes Manuce* (1873), and Omont's *Catalogue* (1892).

Aldred (also Ealdred or Alred) was successively, during the 11th century, abbot of Tavistock, Bishop of Worcester, and Archbishop of York. After his promotion to the see of Worcester in 1044, he undertook several diplomatic missions to the Continent; a journey which he made to Jerusalem in 1058 was a remarkable one for the times. He took an active share in the politics of his time. It has been alleged, on doubtful authority, that he crowned Harold in 1066; he certainly crowned William the Conqueror, and proved a faithful servant to the Norman king. He was active and courageous, but ambitious, greedy, and self-seeking. His appointment to the archbishopric of York in 1060 was confirmed by the pope only on condition that he resigned his former post. Aldred died at York, September 11, 1069. See vols. ii. to iv. of Freeman's *Norman Conquest*.

Aldrich, HENRY, born at Westminster in 1647, passed in 1662 from Westminster School to Christchurch, Oxford, of which he became a canon in 1682, and dean in 1689. He designed the Peckwater Quadrangle, and wrote the well-known catch, 'Hark, the bonny Christchurch Bells;' but he is less remembered as architect or composer, or even as an inveterate smoker, than as the author of the *Artis Logicæ Compendium* (1691), of which a new edition appeared in 1862. He died 14th December 1710.

Aldrich, THOMAS BAILEY, an American poet and novelist, was born at Portsmouth, New Hampshire, U.S., November 11, 1836. While engaged in a New York counting-house, he began to contribute verse to the newspapers, and soon after the publication of *The Bells* (1855), adopted journalism as a profession. He contributed in prose and verse to some of the principal magazines, and from 1881 to 1890 was editor of the *Atlantic Monthly*. Among his novels are *Daisy's Necklace* (1857); *Story of a Bad Boy*; *Marjory Daw*; *Prudence Palfrey*; *Queen of Sheba*; *Stillwater Tragedy*; *Two Bites at a Cherry*. He published some eight or nine volumes of poetry, besides collected editions; and produced several books of travel and reminiscences. He died 19th March 1907. His prose was marked by descriptive power and the gift of humour; his verse includes some of the daintiest work yet produced in America.

Aldridge, IRA, negro tragedian, born about 1805 in Senegambia, in 1825 came to Glasgow from New York to study for a missionary career; but next year, forsaking the pulpit for the stage, made his debut as 'Othello' in a small London theatre. He played in the provinces till 1852; then on the Continent won a high reputation, which London refused to indorse (1857); and finally died at Lodz in Poland, 7th August 1867.

Aldrovandi, ULYSSES, one of the most distinguished naturalists of the 16th century, was born at Bologna in 1522. He was educated partly in his native city, and partly at Padua. In 1550 he was imprisoned as a heretic at Rome; and after his liberation wrote a treatise on ancient statuary. Having taken his degree in medicine at the university of Bologna in 1553, he occupied successively the chairs of Botany and Natural History there, and practised medicine for some time. He established the Botanical Garden at Bologna in 1567, and was for many years engaged in forming a museum of natural history. All his studies and collections were made subservient to his work on Natural History, the first volume of which—on Birds—appeared in 1599. Six volumes appeared during Aldrovandi's life; other seven were published from his manuscripts after his death, which took place in 1605. His work on Botany was also of great importance, and he was the first to collect a real herbarium, as the word is now understood.

Ale would seem to have been the current name in England for malt liquor in general before the introduction of 'the wicked weed called hops' from the Netherlands, about the year 1524. The two names, *ale* and *beer*, are both Teutonic, and seem originally to have been synonymous. According to the *Alvismål*, a didactic Scandinavian poem of the 10th century, it is called 'ale' among men, and among the gods, 'beer.' The word *ale* is still the name for malt liquor in the Scandinavian tongues (Swedish, Danish, and Icelandic, *öl*). The hopped liquor came to be called *beer*, and now this is the generic name in the trade for all malt liquors. The popular application of the two words varies in different localities. In the eastern counties of England, and over the greater portion of the country, *ale* means strong, and *beer*, small malt liquor; while in the west country, *beer* is the strong liquor, and *ale* the small. As now used, *ale* is distinguished from *beer* chiefly by its strength and the quantity of sugar remaining undecomposed. Strong ale is made from the best pale malt; and the fermentation is allowed to proceed slowly, and the ferment to be exhausted and separated. This, together with the large quantity of sugar still left undecomposed, enables the liquor to keep long without requiring a large amount of hops. The Scotch ales are distinguished for the

smallness of the quantity of hops they contain, and for their vinous flavour. They are fermented at an unusually low temperature. The ales of Edinburgh, Wrexham, and Alloa have a high reputation. Burton ale is the strongest made, containing as much as 8 per cent. of alcohol; while the best brown stout has about 6 per cent., and table-beer only 1 or 2 per cent. India pale ale differs chiefly in having a larger quantity of hops (see BEER and FERMENTATION). For the history of ale in our literature, see an interesting book by John Bickerdyke, *The Curiosities of Ale and Beer* (1886).

Alecsandri. See ALEXANDRI.

Aleman, MATEO, a famous Spanish novelist, was born about the middle of the 16th century, at Seville, and died in Mexico in 1610. He was author of a metrical life of St Antony of Padua (1604), and an *Ortografia Castellana* (1608); but his great work is *Guzman de Alfarache*, a novel with a rascal for the hero, which, first published in Madrid in 1599, in half-a-dozen years had run through twenty-six editions, consisting of not less than 50,000 copies. As regards both delineation of manners and purity of style, this masterly creation ranks next to that most celebrated of all the Spanish 'picaresque' novels, *Lazarillo de Tormes*.

Alemanni, the name of a confederacy of several German tribes which began to appear in the country between the Main and the Danube about the beginning of the 3d century. Caracalla (in 211 A.D.) and Alexander Severus fought against them unsuccessfully; but Maximinus at length drove them beyond the Rhine. After his death they again invaded Gaul, but were defeated and pursued into Germany. After 282, being pressed upon from the north-east by the Burgundians, they took up permanent settlements within the Roman boundary from Mainz to Lake Constance. Julian repelled one of their repeated incursions into Gaul in 357. After the 5th century, the confederated nation is spoken of as Alemanni and Suavi or Suevi. In the course of the 4th century, they had crossed the Rhine, and extended as far west as the Vosges, and south to the Alps. At length Clovis broke their power in 496, making them subject to the Frankish dominion; and the southern part of their territory was formed into a duchy called Alemannia. The name of Swabia came to be applied to the part of the duchy lying east of the Rhine. From the Alemanni the French have given the name of *Allemands* and *Allemagne* to Germans and Germany in general, though the proper descendants of the Alemanni are the inhabitants of the north of Switzerland, of Alsace, and part of Swabia.

Alembert. See D'ALEMBERT.

Alembic (Arabic *al-anbiq*, 'the still') is a form of still introduced into chemistry by the alchemists, and used by the more ancient experimenters in manipulative chemistry for the distillation and sublimation of substances such as alcohol, or formic acid, obtained by heating a decoction of red ants in water. The alembic has now been entirely superseded by the retort and receiver, or by the flask attached to a Liebig's condenser. See RETORT.

Alemte'jo, a former province in the south of Portugal, with an area of 9000 sq. m. It is the largest but most sparsely peopled of the provinces, lies N. of Algarve, and stretched from the Atlantic to the Spanish frontier. It is traversed by a number of mountain-chains, and is watered by the Tagus, Guadiana, and Saado or Sado. In the south and west, the climate is hot and dry; the plains are covered with brown heath, broken at intervals by marshy wastes, while the vegetation is extremely scanty. In the east, on the contrary, the valleys are fertile, and the mountains

adorned with forests. The productions include wheat, barley, rice, maize, wine, and fruits. Swine, goats, and sheep are reared; mining, which might be profitably carried on, is neglected. The chief towns are Evora (the capital), Elvas, and Portalegre. Pop. 480,000.

Alençon, chief town of the Norman department of Orne, on the Sarthe, 68 miles SSE. of Caen. The cathedral of Notre Dame (1553-1617) is a Gothic edifice, with good stained glass and the remains of the tombs of the Alençon family, which were almost completely destroyed at the Revolution. The inhabitants produce excellent woollen and linen stuffs, embroidered fabrics, straw-hats, lace-work, artificial flowers, hosiery, &c. The manufacture of the famous Alençon point-lace (*point d'Alençon*) employs barely a tenth part of the 20,000 hands that once engaged in it (see LACE). The cutting of the so-called Alençon diamonds (quartz-crystals), found in the vicinity of the town, is a decayed industry. Pop. 16,000.

The old Dukes of Alençon were a branch of the royal family of Valois, being descended from Charles of Valois, who perished at the battle of Crécy in 1346. His grandson, John I., fell at Agincourt in 1415. René, son of John II., was confined by Louis XI. for three months in an iron cage at Chinon. René's son, who had married the sister of Francis I., commanded the left wing at the battle of Pavia. With him expired the old House of Alençon. The duchy was then given to the Duke of Anjou, brother of King Charles IX. Louis XIV. conferred it upon his grandson the Duc de Berri, and Louis XVI. on his brother the Comte de Provence. More recently the title has been borne by the son of the Duc de Nemours, who was son of Louis-Philippe.

Aleppo (Italianised form of *Haleb*), a Syrian town, till the Great War capital of a Turkish province between the Orontes and the Euphrates, in a fruitful valley watered by the Kuweik. It stands in a large hollow, surrounded by rocky hills of limestone, and beyond is mere desert. The fruitful gardens, celebrated for their excellent plantations of pistachios, are the sole contrast to the desolation which environs the city, whose numberless cupolas and minarets, clean, well-paved streets, and stately houses, make it even yet one of the most beautiful in the East. Formerly it was a principal emporium of trade between Europe and Asia, and was the centre of many of the chief trade routes; especially before the discovery of the sea route to India. It supplied a great part of the East with fabrics of silk, cotton, and wool, and gold and silver stuffs; but in 1822 an earthquake swallowed up two-thirds of the inhabitants, and transformed the citadel into a heap of ruins. The plague of 1827, the cholera of 1832, and the oppression of the Egyptian government, all but completed its destruction. It has only partially recovered from its misfortunes, but is still the principal emporium of the inland commerce of Northern Syria. Its port is Alexandretta or Scanderoon. Aleppo has a large trade in cotton and silk goods, skins, tobacco, wine, and oil; and manufactures much-admired cloth (of silk, cotton, wool; flowered and striped), carpets, cloaks, and soap. English goods are largely imported, and the exports are considerable. The trade is mainly in the hands of the native Christians (Greeks and Armenians), who may number 20,000, and have superseded the European houses that used to be established here. The Jews, 5000 in number, are a very important and wealthy community, occupying a special quarter of the city. The Mohammedans here are less bigoted than in some other cities of Syria; but religious riots sometimes occur—notably in 1850 and 1862. The climate is dry

and not unhealthy; but residents are subject to a painful disorder called Aleppo boils, which most usually break out in the faces of children, last for a year or more, and disfigure the countenance badly. The pop., believed to have been formerly 300,000, was estimated in 1914 at 200,000. Aleppo was connected with Damascus by railway in 1900. It was occupied by the British in October 1918.

Aleshki (formerly *Dnieprovsk*), a town of Taurida, near the Dnieper, and 3 miles from Kheison, noted for its melon-culture and its fisheries; pop. 9500.

Alesia, a town in the east of ancient Gaul, the siege and capture of which formed one of Cæsar's greatest exploits. Vercingetorix, after several defeats, had shut himself up with 80,000 Gauls in Alesia, which was situated on a lofty hill. Cæsar, with his army of 60,000 men, completely surrounded the place; and in spite of the desperate efforts of the besieged, the town was obliged to surrender. Alesia was destroyed by the Normans in 864. Near the site stands the modern village of Alise-Sainte-Reine, in Côte d'Or, W. of Dijon. On the hill Napoleon III. erected in 1864 a colossal statue of Vercingetorix.

Alesius, ALEXANDER, a noted divine and Reformer, whose name was originally Alane, was born in Edinburgh on 23d April 1500. He studied at St Andrews, and became canon of the collegiate church there. Won over to the side of the Reformers, he was obliged to flee to the Continent, and in his absence he was tried and condemned. He eventually settled down at Wittenberg, signed the Augsburg Confession, and gained the friendship of Melancthon. In 1535 Alesius came over to England, was well received by Crammer and Cromwell, and lectured at Cambridge; but the 'Six Articles' compelled him to return to Germany, where he held theological chairs in the universities of Frankfort-on-the-Oder and Leipzig. He died 17th March 1565. He wrote some thirty exegetical and polemical works.

Alessandria, the principal fortress and town of the province of the same name in the north of Italy, is situated in a marshy country near the confluence of the Bormida and Tanaro, 58 miles ESE. of Turin. It was built in 1168 by the inhabitants of Cremona, Milan, and Placentia, as a bulwark against the Emperor Frederick I., and was afterwards called Alessandria in honour of Pope Alexander III. It was taken and plundered in 1522 by Duke Sforza, besieged by the French in 1657, and again taken by Prince Eugene in 1707. In 1800 Bonaparte here concluded an armistice. It was the principal stronghold of the Piedmontese during the insurrection of 1848-49. The citadel is still one of the strongest fortresses in Italy, of enormous size, larger than many a town; and in war the whole surrounding country can be inundated by means of the sluices of the Tanaro. The city contains, exclusive of the garrison, (1911) 75,687 inhabitants, who trade in linens, woollens, silk fabrics, stockings, and wax-candles. The richly decorated cathedral was rebuilt in 1823. Two great fairs are held annually. The city is the meeting-point of several railway lines.—The province, noted for wines, has an area of 1980 sq. m., and a pop. of 800,000. It is a fertile plain on the east, and the west is hilly, with rich wooding.

Alessio, an Adriatic port of Albania, at the mouth of the Drin, 17 miles SE. of Scutari, occupied by the Montenegrins and Serbians in 1911, the Austrians in 1916, and the Italians in 1918; pop. 3000.

Aletsch, the largest glacier (12½ miles long) in Europe, sweeps round the southern side of the Jungfrau. Following the valley in a majestic

curve, it is distinguished by the title Great Aletsch from its two tributary glaciers, the Upper and Middle Aletsch, which branch off to the north-west. At its eastern extremity lies a deep-blue mountain lake, the Merjelen-See (7711 feet), into which huge blocks of detached ice frequently fall. To the NW. lies the Aletschhorn (13,773 feet), the second highest peak in the Bernese Alps, which was first ascended by Mr Tuckett in 1859.

Aleurites. See CANDLE-NUT.

Aleurone, a protein found in many seeds.

Aleutian Islands, a chain of about 150 islands, in several groups, extending westward from the American peninsula of Alaska, and forming an insular continuation of that peninsula towards the Asiatic peninsula of Kamchatka. These islands are chiefly included in the United States territory of Alaska, and lie in lat. 53° N., separating the Sea of Kamchatka on the north from the Pacific Ocean on the south, and are naturally divided into five groups, ranging from east to west in the following order: (1) The Fox Islands, near the extremity of Alaska, of which the largest, Oonimak, is also the largest of the Aleutian chain; other principal islands of this group are Oonalashka and Oomnak. (2) The Andreanov Islands, of which the largest is Atka. (3) The Rat (Kreest) Islands, of which the most important are Keeska, Amchitka, and Semisopochnoi. (4) The Blizhni (Nearer) Islands, so called by the Russians from their nearer proximity to Kamchatka; of these the largest is Attou, the westernmost of the true, or American, Aleutian Islands. (5) Komandorski, or Commander's Islands, a Russian group, lying near Kamchatka, the principal being Behring Island, named from Behring (Bering), a commander in the Russian service, who died here in 1741.

This chain of islands, apparently a continuation of the main Alaskan range of mountains, contains numerous volcanic peaks, some of which are in a state of moderate activity. In some instances these peaks rise from 4000 to 8000 feet high, and are covered with snow. Few trees, and those of stunted growth, are found on these islands, but grasses grow in abundance. Some efforts have been made to cultivate the more common garden vegetables, but with indifferent success.

The aborigines of these islands are believed to have been of Eskimo origin, but from their subjugation by adventurous Russians about the middle of the 18th century, such intimate relations with their conquerors were maintained that they have largely lost their tribal characteristics. They profess the religion of the Greek Church. At Iliuluk, on the island of Oonalashka, are a church, the custom-house, and important trading establishments. The islands abound in springs, and are overrun with foxes, dogs, and reindeer; while the coasts swarm with fish and seals. The inhabitants, once 30,000, are now about 2000. They hunt and fish, and their trade is chiefly in furs and fish. In summer they live in tents or booths, in winter in huts of stone or snow, or underground retreats.

See Greely's *Handbook of Alaska* (1909) and other books named at Alaska.

Alewife (*Alosa tyrannus*), a fish of the same genus with the Shad (q.v.), which, in the end of spring and beginning of summer, appears in great numbers on the eastern coast of North America, and enters the mouths of rivers to spawn. It appears in Chesapeake Bay in March, on the coasts of New York and New England in April, and on those of the British provinces about the 1st of May. It abounds in the Bay of Fundy, but is more rare in the Gulf of St Lawrence; and the Bay of Miramichi appears to be its northern limit. It ascends

rivers only as far as the tide extends, and after spawning, returns to the sea in the middle of summer. It prefers a soft, muddy bottom. Its length is not more than 12 inches. The alewife is called *spring herring* in some places, and *gaspereau* by the French Canadians. In the United States it is considered much superior to the herring. The fishery is prosecuted in the rivers, by small-meshed seine-nets set across the stream. Large quantities are taken in the rivers of New England, New Brunswick, and Nova Scotia. The harbour of St John, New Brunswick, alone produces from 12,000 to 20,000 barrels annually. This fish, in a salted state, forms a considerable article of export from the northern parts of America to the West Indies.

Alexander the Great, son of Philip of Macedon and Olympias, daughter of Neoptolemus of Epirus, was born at Pella, 356 B.C. His mind was formed chiefly by Aristotle, who instructed him in every branch of human learning, especially in the art of government. Alexander was 16 years of age when his father marched against Byzantium, and left the government in his hands during his absence. Two years afterwards, he displayed singular courage at the battle of Chæronea (338 B.C.), where he overthrew the Sacred Band of the Thebans. 'My son,' said Philip, as he embraced him after the conflict, 'seek for thyself another kingdom, for that which I leave is too small for thee.' The father and son quarrelled, however, when the former divorced Olympias. Alexander took part with his mother, and fled to Epirus, to escape his father's vengeance; but receiving his pardon soon afterwards, he returned, and accompanied him in an expedition against the Triballi, when he saved his life on the field. Philip, being appointed generalissimo of the Greeks, was preparing for a war with Persia, when he was assassinated (336 B.C.), and Alexander, not yet twenty years of age, ascended the throne. After punishing his father's murderers, he marched on Corinth, and in a general assembly of the Greeks he caused himself to be appointed to the command of the forces against Persia. On his return to Macedon, he found the Illyrians and Triballi up in arms, whereupon he forced his way through Thrace, and was everywhere victorious. But now the Thebans had been induced, by a report of his death, to take up arms, and the Athenians, stimulated by the eloquence of Demosthenes, were preparing to join them. To prevent this coalition, Alexander rapidly marched against Thebes, which, refusing to surrender, was conquered and razed to the ground. Six thousand of the inhabitants were slain, and 30,000 sold into slavery; the house and descendants of the poet Pindar alone being spared. This severity struck terror into all Greece. The Athenians were treated with more leniency.

Alexander, having appointed Antipater his deputy in Europe, now prepared to prosecute the war with Persia. He crossed the Hellespont in the spring of 334 B.C., with 30,000 foot and 5000 horse, attacked the Persian satraps at the river Granicus, and gained a complete victory, overthrowing the son-in-law of Darius with his own lance. As a result of the battle, most of the cities of Asia Minor at once opened their gates to the conqueror. Alexander restored democracy in all the Greek cities; and as he passed through Gordium, cut the Gordian-knot (q.v.), which none should loose but the ruler of Asia. During a dangerous illness at Tarsus, brought on by bathing in the Cydnus, he received a letter insinuating that Philip, his physician, had been bribed by Darius to poison him. Alexander handed the letter to Philip, and at the same time swallowed the draught which the latter had prepared. As soon as he recovered, he

advanced towards the defiles of Cilicia, in which Darius had stationed himself, with an army of 600,000 men. He arrived in November 333 B.C. in the neighbourhood of Issus, where, on the narrow plain between the mountains and the sea, the unwieldy masses of the Persians were thrown into confusion by the charge of the Macedonians, and fled in terror. On the left wing, 30,000 Greek mercenaries held out longer, but they, too, were at length compelled to yield. All the treasures as well as the family of Darius fell into the hands of the conqueror, who treated them with the greatest magnanimity. Overtures for peace, made by Darius on the basis of surrendering to Alexander all Asia west of the Euphrates, were rejected. Alexander now turned towards Syria and Phœnicia. He occupied Damascus, where he found princely treasures, and secured to himself all the cities along the shores of the Mediterranean. Tyre, confident in its strong position, resisted him, but was conquered and destroyed, after seven months of incredible exertion (332 B.C.). Thence he marched victoriously through Palestine, where all the cities submitted to him except Gaza; it shared the same fate as Tyre. Egypt, weary of the Persian yoke, welcomed him as a deliverer; and in order to strengthen his dominion here, he restored all the old customs and religious institutions of the country, and founded Alexandria in the beginning of 331 B.C. Thence he marched through the Libyan Desert, in order to consult the oracle of Ammon, whose priest saluted him as a son of Zeus; and he returned with the conviction that he was indeed a god. He then again set out to meet Darius; in October 331 B.C., a great battle was fought on the plain stretching eastward to Arbela. Notwithstanding the immense superiority of his adversary, who had collected a new army of more than a million men, Alexander was not for a moment doubtful of victory. Heading the cavalry himself, he rushed on the Persians, and put them to flight; then hastened to the assistance of his left wing, which, in the meanwhile, had been sorely pressed. He was anxious to make Darius a prisoner, but Darius escaped on horseback, leaving his baggage and all his treasures a prey to the conqueror. Babylon and Susa, the treasure-houses of the East, opened their gates to Alexander, who next marched towards Persepolis, the capital of Persia, which he entered in triumph.

The marvellous successes of Alexander now began to dazzle his judgment and to inflame his passions. He became a slave to debauchery, and his caprices were as cruel as they were ungrateful. In a fit of drunkenness, and at the instigation of Thais, an Athenian courtesan, he set fire to Persepolis, the wonder of the world, and reduced it to a heap of ashes; then, ashamed of the deed, he set out with his cavalry in pursuit of Darius. Learning that Bessus, the Bactrian satrap, held him a prisoner, he hastened his march, in the hope of saving him, but he found him mortally wounded (330 B.C.). He mourned over his fallen enemy, and caused him to be buried with all the customary honours; whilst he hunted down Bessus, who himself aspired to the throne, chasing him over the Oxus to Sogdiana (Bokhara). Having discovered a conspiracy in which the son of Parmenio was implicated, he put both father and son to death, though Parmenio himself was innocent of any knowledge of the affair. This cruel injustice excited universal displeasure. In 329 he penetrated to the furthest known limits of Northern Asia, and overthrew the Scythians on the banks of the Jaxartes. In the following year he subdued the whole of Sogdiana, and married Roxana, whom he had taken prisoner. She was the daughter of Oxyartes, one of the enemy's captains, and was

said to be the fairest of all the virgins of Asia. The murder of his foster-brother, Clitus, in a drunken brawl, was followed, in 327 B.C., by the discovery of a fresh conspiracy, in which Callisthenes, a nephew of Aristotle, was falsely implicated. For challenging Alexander's divinity, he was cruelly tortured and hanged.

In 326 B.C., proceeding to the conquest of India, hitherto known only by name, Alexander crossed the Indus near to the modern Attock, and pursued his way under the guidance of a native prince to the Hydaspes (Jhelum). He there was opposed by Porus, another native prince, whom he overthrew after a bloody contest, and there he lost his charger Bucephalus (q.v.); thence he marched as lord of the country through the Punjab, establishing Greek colonies. He then wished to advance to the Ganges, but the general murmuring of his troops obliged him, at the Hyphasis (modern Sutlej), to commence his retreat. On regaining the Hydaspes, he built a fleet, and sent one division of his army in it down the river, while the other followed along the banks, fighting its way through successive Indian armies. At length, having reached the ocean, he ordered Nearchus, the commander of the fleet, to sail thence to the Persian Gulf, while he himself struck inland with one division of his army, in order to return home through Gedrosia (Beluchistan). During this march his forces suffered fearfully from want of food and water. Of all the troops which had set out with Alexander, little more than a fourth part arrived with him in Persia (325 B.C.). At Susa he married Stateira, the daughter of Darius, and he bestowed presents on those Macedonians (some 10,000 in number) who had married Persian women, his design being to unite the two nations. He also distributed liberal rewards among his soldiers. Soon afterwards he was deprived, by death, of his favourite Hephestion. His grief was unbounded, and he interred the dead man with kingly honours. As he was returning from Ecbatana to Babylon, it is said that the Magi foretold that the latter city would prove fatal to him; but he despised their warnings. On the way, he was met by ambassadors from all parts of the world—Libya, Italy, Carthage, Greece, the Scythians, Celts, and Iberians. At Babylon he was busy with gigantic plans for the future, both of conquest and civilisation, when he was suddenly taken ill after a banquet, and died eleven days later, 323 B.C., in the 32d year of his age, and the thirteenth of his reign. His body was deposited in a golden coffin at Alexandria, by Ptolemæus, and divine honours were paid to him, not only in Egypt, but in other countries. He had appointed no heir to his immense dominions; but to the question of his friends, 'Who should inherit them?' he replied, 'The most worthy.' After many disturbances, his generals recognised as kings the weak-minded Aridaeus—a son of Philip by Philinna, the dancer—and Alexander's posthumous son by Roxana, Alexander Ægus, while they shared the provinces among themselves, assuming the title of satraps. Perdiccas, to whom Alexander had, on his death-bed, delivered his ring, became guardian of the kings during their minority. The empire of Alexander soon broke up, and his dominions were divided amongst his generals. See GREECE, PTOLEMY, SELEUCIDÆ.

Alexander was more than a conqueror. He diffused the language and civilisation of Greece wherever victory led him, and planted Greek kingdoms in Asia, which continued to exist for some centuries. At the very time of his death, he was engaged in devising plans for the drainage of the unhealthy marshes around Babylon, and a better irrigation of the extensive plains. It is even

supposed that the fever which he caught there, rather than his famous drinking-bout, was the real cause of his death. To Alexander the ancient world owed a vast increase of its knowledge in geography and natural history; and he taught Europeans the road to India. See Freeman's *Historical Essays* (1873); Curtius, *Rise of the Macedonian Empire* (1878); Mahaffy, *Alexander's Empire* (1887); Dodge, *Alexander* (Boston, 1890); Wheeler (1900); German works by Kaeist (1887) and Droysen (1885), and French by Joubert (1889).

The wonderful element in the campaigns of Alexander, and his tragical death at the height of his power, threw a rare romantic interest around his figure. It is ever the fate of a great name to be enshrined in fable, and Alexander soon became the hero of romantic story, scarcely more wonderful than the actual, but growing from age to age with the mythopoetic spirit which can work as freely in fact as fiction. The earliest form of the story which we know is the great romance connected with the name of Callisthenes, which, under the influence of the living popular tradition, arose in Egypt about 200 A.D., and was carried through Latin translations to the West, through Armenian and Syriac versions to the East. It became widely popular during the middle ages, and was worked into poetic form by many writers in French and German. Alberich of Besançon wrote in Middle High German an epic on the subject in the first half of the 12th century, which was the basis of the German 'Pfafe' Lamprecht's *Alexanderbuch* (ed. by Hinzl, Halle, 1884), also of the 12th century. The French poets Lambert li Court and Alexandre de Bernay composed, between 1180 and 1190, a romance of Alexander, the twelve-syllable metre of which gave rise to the name *Alexandrines*. The German poem of Rudolf of Ems was based on the Latin epic of Walter of Châtillon, about 1200, which became henceforward the prevailing form of the story. In contrast with it is the 13th-century English epic of Alexander (in vol. i. of Weber's *Metrical Romances*, 1810), based on the Callisthenes version. The story appears also in the East, worked up in conjunction with myths of other nationalities, especially the Persian. It appears in Firdusi, and, among later writers, in Nizami. From the Persians both the substance of the story and its form in poetical treatment have extended to Turks and other Mohammedans, who have interpreted Alexander as the *Dsulkarnain* ('two horned') of the Koran, and to the Hindus, which last had preserved no independent traditions of Alexander. See Spiegel, *Die Alexandersage bei den Orientalen* (1851); Paul Meyer, *Alexandre le Grand dans la Littérature Française au Moyen-âge* (1886); works by Nöldeke (1890) and Hilka (1911).

Alexander I., king of Scotland, the fourth son of Malcolm Canmore, was born about 1078, and in 1107 succeeded his brother, Edgar, only however to that part of the kingdom north of the Firths of Forth and Clyde (see DAVID I.). He married Sibylla, a natural daughter of Henry I. of England, and his reign was comparatively untroubled, though about 1115 he had to quell an insurrection of the northern clans. He founded the abbeys of Scone and Incheolm, and initiated a diocesan episcopate; whilst his determined resistance to the claims of York and Canterbury to supremacy over the see of St Andrews, did much to secure the independence, not only of the Scottish Church, but of Scotland itself. He died at Stirling in 1124.

Alexander II., born at Haddington in 1198, succeeded his father, William the Lion, in 1214. He early displayed that wisdom and strength of character, in virtue of which he holds so high a

place in history among Scottish kings. The first act of his reign was to enter into a league with the English barons who had combined to resist the tyranny of King John. This drew down upon him and his kingdom the papal excommunication; but two years later, the ban was removed, and the liberties of the Scottish Church were even confirmed. On the accession of Henry III. to the English throne, Alexander brought the feuds of the two nations to a temporary close by a treaty of peace (1217), in accordance with which he married Henry's eldest sister, the Princess Joan (1221). The alliance thus established was broken after the death, without issue, of Queen Joan (1238), and the second marriage of Alexander with the daughter of a noble of France. In 1244 Henry marched against Scotland, to compel Alexander's homage. In this emergency, the Scottish king received the steady support of the barons, whose ordinary policy was opposition to the crown, and, according to Matthew Paris, he found himself, in a short time, at the head of 100,000 foot and 10,000 horse. A peace was concluded without an appeal to arms. In 1249, while engaged in an expedition to wrest the Hebrides from Norway, Alexander died of fever at Kerrera, a small island opposite Oban. During his reign, Argyll and Galloway were brought into subjection to the crown.

Alexander III., born in 1241, succeeded his father, Alexander II., at the age of eight, and two years later married the Princess Margaret, eldest daughter of Henry III. of England (1251). His tender age enabled Henry to prosecute successfully for a time his schemes for obtaining entire control over Scotland; but long before he reached manhood, Alexander displayed so much energy and wisdom as to give assurance that when the administration of affairs should come into his hands, it would be vain to think of reducing him to submission. Very shortly after he had come of age, his energies were summoned to the defence of his kingdom against the formidable invasion of Haco, king of Norway (1263), who claimed the sovereignty of the Western Isles. In attempting a landing at Largs, on the coast of Ayr, the Norwegian prince sustained a total defeat; and Alexander, as the result of this important victory, secured the allegiance both of the Hebrides and of the Isle of Man. The alliance between Scotland and Norway was strengthened in 1282 by the marriage of Alexander's only daughter, Margaret, to Eric, king of Norway. This princess died in the following year, leaving an infant daughter, Margaret, commonly designated the Maid of Norway, whose untimely death, on her way to take possession of her throne, was the occasion of so many calamities to Scotland. During the concluding years of Alexander's reign, the kingdom enjoyed a peace and prosperity which it did not taste again for many generations. The justice, liberality, and wisdom of the king endeared his memory to his subjects, while the misfortunes that followed his death, heightened the national sense of his loss. His only surviving son, who had married the daughter of Guy, Count of Flanders, died without issue in 1284; and in the next year, Alexander contracted a second marriage with Joleta, daughter of the Count de Dreux. The hopes of the nation were soon after clouded by his untimely death. Riding on a dark night between Burntisland and Kinghorn, he fell with his horse, and was killed on the spot, 12th March 1286. A monument (1887) marks the scene of his death.

Alexander I., Emperor and Autocrat of All the Russias (1801-25), was born in 1777. His father, Paul (q.v.), had no control over his education; it was conducted by his grandmother, the Empress Catharine, with the help chiefly of Laharpe,

a Swiss; and the young prince was brought up in the most advanced and enlightened opinions of the 18th century. His mother was Maria of Württemberg. In 1793 he married Elizabeth of Baden, and, on the assassination of his father in 1801, succeeded him upon the throne. Alexander knew of the conspiracy to dethrone his father, but he was in no way privy to his murder. The young ruler seemed deeply penetrated with a sense of his obligation to make his people happy and to promote their civilisation and prosperity. Many changes were at once initiated. Education was promoted; the universities of Moscow, Vilna, and Dorpat were remodelled; and new ones were founded at Kazan, Kharkoff, and St Petersburg. Steps were taken for alleviating serfdom. The press-censorship was relaxed, and a milder system of administration was introduced.

The accession of Alexander was soon—most distinctly—felt in the conduct of foreign affairs. In 1801 he concluded a convention with Britain, renouncing the Armed Neutrality and putting an end to hostilities. He next entered, along with France, into negotiations respecting the indemnification of the minor states in Germany and Italy; but discovering how little Napoleon intended any real compensation, he broke with France, and joined the coalition of 1805. He was present at the battle of Austerlitz, where the allied armies of Austria and Russia were defeated, and retired with the remains of his forces into Russia, declining to enter into the treaty that followed. Next year, he came forward as the ally of Prussia; but after the battles of Eylau and Friedland, in 1807, he was obliged to conclude the peace of Tilsit, in which he managed to prevent the restoration of the kingdom of Poland, and to mitigate the hard fate of the king of Prussia. During the war with France, Alexander had also to carry on hostilities with Persia and with Turkey.

In pursuance of the stipulations of Tilsit, Alexander acceded with his huge empire to the French Continental System, thus altering entirely the foreign policy of Russia. He began by declaring war on Britain in 1808, and, attacking her ally Sweden, wrested from that country the province of Finland. In the war of France against Austria in 1809, Alexander took only a lukewarm part. Against the Porte he renewed the war, which was continued till the peace of Bucharest in 1812.

The unnatural alliance of Alexander with Napoleon could not, however, be maintained. The pressure of the continental system on the material resources of Russia, the despotic changes made by Napoleon, the augmentation of the duchy of Warsaw, the proffers of alliance by England and Sweden, awoke in Alexander the thought of a decisive contest against the subjugator of Europe and the disturber of the peace of the world. When this gigantic struggle at last began (1812), Russia brought into the field an army of 300,000 men. During the French invasion, Alexander was not present with his troops, but he took an active part in the great struggles of 1813 and 1814. At the occupation of Paris after the downfall of Napoleon in 1814, Alexander was the central figure of the politics and diplomacy of the time. His courtesy, humanity, and regard for the feelings and interests of the French, won for him a personal regard amounting to enthusiasm. He was received with the same feeling in London, which he visited after the treaty of Paris in June 1814. After a short residence in his own capital, he repaired to the Congress of Vienna. Here he laid claim to Poland as essential to the interests of Russia, but promised to confer on it a constitution. On the return of Napoleon from Elba, Alexander urged the energetic prosecution of the war against the common enemy;

yet on this occasion, too, France owed much to his generosity.

In the end of October 1815, Alexander returned to his own dominions. Under his guidance, Russia had become the leading power on the Continent; the limits of the empire had extended; and notwithstanding the war, the earlier legislative reforms had begun to act favourably on the industry and well-being of the nation. At Paris, Alexander had met Madame Krüdener, who gave a new direction to his mind, and his French ideas gave place to a decided pietism, with sympathies for Protestant and English ways of thinking. The British and Foreign Bible Society established itself at St Petersburg with great success. Alexander received a deputation of Quakers, and prayed and wept with them. The most important political outcome of this period was the Holy Alliance (q.v.), founded by Alexander, and accepted by all the leading Christian countries of Europe, except Britain. Many causes contributed to force Alexander into a reactionary course. He yielded to the influence of Metternich, the celebrated Austrian statesman, and the Holy Alliance became an instrument of political reaction throughout Europe. At home he adopted severe measures of repression, which were in entire contradiction to the principles of his youth.

The progress of the revolt in Greece brought the policy of the emperor into complete opposition to the deepest sympathies of the nation. The Russian people were profoundly interested in the Greek struggle; but the emperor condemned the rising as insurrection. The death of his only and much-loved natural daughter, the terrible inundation suffered by St Petersburg in 1824, in which he exposed himself to personal danger, and the alarm caused by a Russo-Polish conspiracy against all the members of the House of Romanof, contributed not a little to break the heart of the emperor, and completely destroy the composure of his mind. Weary with the burden of governing a vast empire, not yet ripe for the advanced views which he himself cherished, he commenced, in September 1825, a journey to the Crimea for the benefit of his health. He died at Taganrog, December 1, 1825. It is reported that about this time he was heard to repeat: 'And yet men may say of me what they please, I have lived and will die a republican.' The rumour that he had been poisoned is altogether groundless. Shortly before his death, he learned the details of the conspiracy which his brother and successor, Nicholas I. (q.v.), had put down.

See vol. x. of the *Cambridge Modern History* (1907); Hodgetts, *The Court of Russia in the 19th Century* (1908).

Alexander II., Emperor of Russia (1855-81), was born April 29, 1818. He was carefully educated by his father, Nicholas, who professed himself delighted with the manifestations of 'true Russian spirit' in his son. At sixteen, he was declared of age, made commandant of the Lancers of the Guard, Hetman of the Cossacks, first aide-de-camp of the emperor, and subjected daily to a life of manœuvring, reviewing, and military parade, which at last seriously injured his health. He then travelled through Germany to recruit his energies, and while there in 1841, concluded a marriage with the Princess Marie (1824-80), daughter of the Grand-duke of Hesse. He now vigorously applied himself to his duties as chancellor of the university of Finland. By his dexterous and winning manners, he found his way to the hearts of the Finns, and weakened their ancient love of independence. On his accession to the throne, March 2, 1855, he found himself in a very critical position. He had two parties to conciliate—the old Muscovite party, zealous for the prosecution of the Crimean war, and the more peaceable portion of the nation, with whom he sympathised.

By temporising he was enabled to conclude a peace. Throughout his reign, he had to hold the balance between Conservatives and extreme Radicals, but succeeded in guiding and promoting reform. The grand achievement of his reign was the emancipation, which had been contemplated by Nicholas I., of the serfs—23,000,000 souls—in 1861. Reforms of the tribunals, of civil and criminal procedure, and of municipal institutions followed. In 1865 Alexander established elective representative assemblies in the provinces. He resisted strenuously all foreign interference with Polish affairs during the insurrection of 1863, which was suppressed with great severity. During his reign, the Russian empire was widely extended in two important regions, in the Caucasus and in Central Asia. The capture of Schamyl, the famous Circassian chief, in 1859, closed in favour of Russia her long struggle with the tribes of that country. In 1864 Russia began her decided advance against the khanates of Central Asia, and in a few years reduced them all more or less completely to subjection. During the Franco-German war of 1870-71, Alexander maintained a very sympathetic attitude towards Germany, a policy which was continued and extended in subsequent alliances both with that country and Austria. The marriage of his only daughter Marie with the Duke of Edinburgh in 1874 had no permanent effect in allaying the mutual jealousies of Russia and England. The Czar shared the national sympathy with the Slavic races under Turkish rule, and took the field with the army during the momentous war between Russia and Turkey in 1877-8. But the most remarkable feature of the second half of his reign was the struggle of the Russian autocracy with the revolutionary party, called Nihilists. Like his uncle, Alexander I., he was personally a liberal and humane monarch, but he could not keep pace with the more forward portion of his subjects; hence the reactionary tendency of many of his later measures. His government repressed the revolutionists most severely, and they sought vengeance by attacking the person of the Czar and his officers. Repeated attempts were made to assassinate Alexander. In 1879 he was shot at in his capital; in the same year, the train in which he was supposed to be travelling was blown up by an elaborate mine beneath the railway; in 1880 a violent and destructive explosion was effected by dynamite below the imperial apartments in the Winter Palace at St Petersburg. On 13th March 1881 he was fatally injured by a bomb thrown at him near his palace.

See Lives by Laferté (pen-name of hismorganatic wife, 1882) and Tatistchev (1903).

Alexander III., son of Alexander II., was born 10th March 1845, and married Dagmar, daughter of Christian IX. of Denmark, 1866. After his father's death, through fear of assassination he shut himself up in his palace at Gatchina. His coronation was postponed till 1883, and was celebrated with extraordinary magnificence, and with national festivities lasting several days. Through the fall of Merv, the subjugation of the Turkomans in Central Asia was completed. In 1885 hostilities with Britain, with regard to the defining of the frontier between the Russian territories and Afghanistan (q.v.), for a time seemed imminent. As regards European affairs, he broke away from the triple alliance between Russia, Germany, and Austria, and looked rather to France. He was aggrieved by the new Bulgarian spirit. His home policy was reactionary, though strong efforts were made to prevent malversation by officials, and stern economies were practised. The liberties of the Baltic provinces and of Finland were curtailed, the Jews were oppressed, and old Russian orthodoxy

was favoured. Several Nihilist attempts were made on his life, and he kept himself practically a prisoner in his palace. He died at Livadia, 1st November 1894. See RUSSIA, BULGARIA, and a Life by Lowe (1894).

Alexander VI. is infamous amongst popes (See POPE). His most conspicuous qualities were a cunning and insidious cruelty, united with great fearlessness in danger, an unwearied perseverance and vigilance in all his undertakings, a soft and plausible manner towards his inferiors, a harsh and grasping spirit towards the rich. In spite of his talents and his love of art and science, he disdained, throughout his dissolute career, no means of gratifying his lust—not even perjury, murder, poisoning. He was born in Spain, at Jativa in Valencia, 1431. His real name was Rodrigo Lançol or Lenzuoli, but he assumed the ancient and famous one of his mother's family, Borgia. The beautiful Rosa Vanozza de Cattanei bore him five children, two of whom, Cesare and Lucrezia, equalled himself in notoriety (see BORGIA). In 1455 he was made a cardinal by his uncle, Calixtus III., and in 1492, on the death of Innocent VIII., was elevated to the papal chair, which he had previously secured by flagrant bribery. The long absence of the popes from Italy had weakened their authority and curtailed their revenues. To compensate for this loss, Alexander endeavoured to break the power of the Italian princes, and to appropriate their possessions for the benefit of his own family. He employed the most execrable means to gain this end. He died in 1503, most likely of fever, but according to popular tradition, through having accidentally partaken of poisoned wine, intended for ten cardinals, his guests. He apportioned the New World between Spain and Portugal; whilst under his pontificate the censorship of books was introduced, and Savonarola, the earnest and eloquent Florentine priest, who had advocated his deposition, was condemned to be burnt as a heretic. The researches of Von Reumont and Gregorovius have cleared his memory from some at least of the most odious charges; and there can be no question that many of the crimes ascribed to him were the direct or indirect work of Cesare Borgia. See Creighton's *History of the Papacy*, vols. ii. and iii. (1887), and Life by Mathew (1912).

Alexander of BATTENBERG, Prince of Bulgaria. See BULGARIA.

Alexander OF HALES, the 'Irrefragable Doctor,' was originally an ecclesiastic in Gloucestershire, but having repaired to the schools of Paris, and become a noted professor of philosophy and theology, he suddenly, in 1222, entered the order of the Franciscans. He continued to lecture, however, till seven years before his death, in 1245. His chief and only authentic work is the ponderous *Summa Universa Theologiae* (best ed., Venice, 1576, 4 vols.), written at the command of Pope Innocent IV., and enjoined by his successor, Alexander IV., to be used by all professors and students of theology in Christendom. Alexander gave the doctrines of the church a more rigorously syllogistic form than they had previously had, and may thus be considered as the author of the scholastic theology. Instead of appealing to tradition and authority, he deduces with great subtlety, from assumed premises, the most startling doctrines of Catholicism, especially in favour of the prerogatives of the papacy. He refuses any toleration to heretics, and would have them deprived of all property; he absolves subjects from all obligation to obey a prince that is not obedient to the church. The spiritual power, which blesses and consecrates kings, is, by that very fact, above all

temporal powers, to say nothing of the essential dignity of its nature. It has the right to appoint and to judge these powers, while the pope has no judge but God. In ecclesiastical affairs, also, he maintains the pope's authority to be full, absolute, and superior to all laws and customs.

Alexander, ARCHIBALD, an American divine of Scottish descent, was born in Virginia, 17th April 1772, and died at Princeton, New Jersey, 22d October 1851. He studied theology, and performed itinerant missionary work in various parts of Virginia; became president of Hampden Sidney College in 1796, and pastor of a Presbyterian church in Philadelphia in 1807. On the establishment of Princeton College, he was appointed its first theological professor in 1812, which position he held till his death. Amongst other works, he published *Outlines of the Evidences of Christianity*; *Treatise on the Canon of the Scriptures* (1826); *History of the Patriarchs* (1833); and *History of the Israelitish Nation* (1852); his *Moral Science* was posthumous.—His eldest son, JAMES WADDELL ALEXANDER (1804-59), was a Presbyterian minister in Virginia, New Jersey, and at New York; and afterwards professor in Princeton Theological Seminary. He contributed to the *Princeton Review*, wrote over thirty children's books, a life of his father, and miscellaneous works. See his Life by Dr Hall (1860).—JOSEPH ADDISON ALEXANDER, third son (1809-60), graduated at Princeton in 1826, lectured there on Biblical Criticism and Ecclesiastical History, and for the last eight years of his life filled the chair of Biblical and Ecclesiastical History. He was engaged at the time of his death, along with Dr Hodge, on a commentary of the New Testament. He is best known by his commentaries and *Prophecies of Isaiah* (1846-7; revised edition, 1864), and the *Psalms Translated and Explained* (3 vols. 1850).

Alexander, SIR W. See STIRLING (EARL OF).

Alexander, WILLIAM, Bishop of Derry and Raphoe from 1867, and Archbishop of Armagh and Primate of all Ireland, 1896-1910, was born at Londonderry, 13th April 1824, and educated at Oxford. He died 12th September 1911. An eloquent preacher, he perhaps put his best work into the volume of poems named (1886) from *Augustine's Holiday*, in the 1900 edition from *The Finding of the Book*. See Life by his daughter (1913). He married in 1850 Cecil Frances Humphreys (1818-95), writer of graceful poetry, sacred and for children—her best-known hymns or poems being 'Jesus calls us o'er the tumult,' 'There is a green hill far away,' and 'The Burial of Moses.'

Alexander, WILLIAM LINDSAY (1808-84), Scottish Congregational divine, born at Leith, educated at Edinburgh, Glasgow, and St Andrews, removed in 1835 from a charge in Liverpool to Edinburgh, where he was pastor and principal of the Congregational College. See Life by Ross (1887).

Alexander Nevski, a Russian hero and saint, born in 1218 A.D., was the son of the Grand-duke Jaroslav, of Novgorod, who was forced to submit to the Mongol dominion in 1238. Alexander received the surname of Nevski on account of the splendid victory over the Swedes, which he achieved in 1240, on the Neva, near where St Petersburg now stands. At the death of his father in 1247, he became his successor, and opposed a papal attempt to reunite the Greek and Roman churches. To the end of his life he remained a vassal of the Tatars or Mongols, but knew how to moderate their tyranny. He was a good prince; and when he died in 1263, the gratitude of the nation canonised him. Peter the Great honoured his memory by building a magnificent convent on the spot where Alexander had fought his great

battle, and by founding the knightly order of Alexander Nevski.

Alexander Seve'rus, a Roman emperor, born in 205 A.D., was the cousin and adopted son of Heliogabalus, whom he succeeded in 222. The excellent education which he received from his mother, Julia Mamæa, rendered him one of the best princes in an age when virtue in a monarch was reckoned more dangerous than vice. He sought the society of the learned; Paulus and Ulpianus were his counsellors; Plato and Cicero were, next to Horace and Virgil, his favourite authors. Although a pagan, he revered the doctrines of Christianity, and often quoted that saying: 'Whatsoever ye would that men should do to you, do ye even so to them.' Beloved as he was by the citizens on account of his equity, he soon became an object of hatred to the unruly prætorian guards. His first expedition (231-33), against Artaxerxes, king of Persia, was happily terminated by a speedy overthrow of the enemy. But during one which he undertook in 234 against the Germans on the Rhine, to defend the frontiers of the empire from their incursions, an insurrection broke out among his troops, headed by Maximinus, in which Alexander was murdered, along with his mother, not far from Mainz (235).

Alexanders (*Smymnatum olusatrum*), a biennial plant of the natural order Umbelliferae (q.v.), found in waste ground, near ruins, &c. in Britain and the south of Europe. The plant has an aromatic taste, strong and pungent, but becomes rather pleasant when blanched, and was formerly much cultivated and used in the same way as celery, although at present it is little regarded. The frequency of its occurrence near ruins in Britain, may probably be referred to its former cultivation. The fruit is carminative.—*S. perfoliatum*, a native of Italy, is used in the same way.—Another umbelliferous genus (*Zizia*) is popularly called Golden Alexanders in North America.

Alexandra. See EDWARD VII.

Alexandra Land, the westernmost islands of Franz Josef Land (q.v.); also an old name for the Northern Territory of Austalia.

Alexandra Park, a public recreation ground (1863) for north London, 6 miles N. of Charing Cross.

Alexandretta. See SCANDEROON.

Alexandri, or ALECSANDRI, VASILIO, Rumanian poet and patriot, was born at Jassy in 1821. Educated at Paris, he returned to Jassy in 1839, and attached himself to a party of young men, who, influenced by Western ideas, were at once ambitious of literary distinction, and zealous for political equality and for Rumanian nationality. His share in the abortive revolution of 1848 obliged him for a time to take refuge in Paris, but he then and always laboured incessantly through the press and otherwise for Rumanian independence. He was foreign minister under Ghika in 1859-60. His first volume of verse appeared in 1852; his complete works including dramas, in 1873-76. He died 4th September 1890.

Alexandria was founded by Alexander the Great in the autumn of the year 332 B.C. It was situated originally on the low tract of land which separates the lake Mareotis from the Mediterranean, about 14 miles west of the Canopic mouth of the Nile. Before the city, in the Mediterranean, lay an island, upon the N.E. point of which stood the famous lighthouse, the Pharos, built in the time of Ptolemy I. in the 3d century B.C., and said to have been 113 metres high. The island was connected with the mainland by a mole, called the Heptastadium, thus forming the two harbours. The plan of Alexandria was designed by the archi-

tect Deinocrates, and its original extent is said to have been about 4 miles in length, with a circumference of 15 miles. It was intersected by two straight main streets, crossing each other at right angles in a large square, and adorned with handsome houses, temples, and public buildings. The most magnificent quarter of the city was that called the Brucheion, which ran from the centre to the eastern harbour. This quarter of the city contained the palaces of the Ptolemies, the Museum, for centuries the focus of the intellectual life of the world, and the famous library; the mausoleum of Alexander the Great and of the Ptolemies, the temple of Poseidon, and the great theatre. To the south was the beautiful gymnasium. The Serapeum, or temple of Serapis, stood in the western division of the city, which formed the Egyptian quarter, and was called Rhacôtis; a small town of that name had occupied the site before the foundation of Alexandria. To the west of the city lay the great Necropolis, and to the east the race-course and suburb of Nicopolis. Much of the space under the houses was occupied by vaulted subterranean cisterns, which were capable of containing a sufficient quantity of water to supply the whole population of the city for a year. From the time of its foundation, Alexandria was the Greek capital of Egypt. Its population, in the time of its prosperity, is said by Diodorus to have amounted to about 300,000 free citizens, and probably a larger number of slaves. This population consisted mostly of Greeks, Jews, and Egyptians, together with settlers from all nations of the known world. After the death of Alexander the Great, Alexandria became the residence of the Ptolemies. They made it, next to Rome and Antioch, the most magnificent city of antiquity, as well as the chief seat of Greek learning and literature, which spread hence over the greater part of the ancient world. The situation of the city, at the point of junction between the East and West, rendered it the centre of the commerce of the world, and raised it to the highest degree of prosperity.

Alexandria had reached its greatest splendour when, on the death of Cleopatra, the last of the Ptolemies, in 30 B.C. it came into the possession of the Romans. Its glory was long unaffected, and it was the emporium of the world's commerce, especially for corn. In the reign of Caracalla, however, it suffered severely; and the rise of Constantinople promoted the decay of Alexandria. Christianity was introduced, according to tradition, by St Mark. In the 2d century its adherents were very numerous; amongst its teachers were Clemens Alexandrinus and Origen. The strife between Christianity and heathenism—powerfully described in Kingsley's *Hypatia*—gave rise to bloody contests in Alexandria. The Serapeum, the last seat of heathen theology and learning, was stormed by the Christians in 391 A.D., and converted into a Christian church. Alexandria was a chief seat of Christian theology till it was taken by the Arabs, under Amru, in 641, at which time it was much injured. The choice of Cairo as capital of the Egyptian khalifs hastened the now rapid decay of the city; the discovery of America, and of the passage to India by the Cape of Good Hope, very much diminished its trade; and when, in 1517, the Turks took the place, the remains of its former splendour wholly vanished, walls and buildings being reduced to ruins. In 1778 Alexandria contained no more than 6000 inhabitants. Under Mehemet Ali, however, the tide turned, and the city recovered rapidly. It is now again one of the most important commercial places on the Mediterranean. The Suez Canal diverted part of its trade as the centre of steam communication with India; but this was more

than compensated by the general impetus given by the canal to Egyptian prosperity. In 1882, during the rising of Arabi Pasha, serious damage was done to the city. The Europeans were maltreated; and as Arabi would not desist from strengthening the fortifications, a British fleet, in the interests of the khedive, bombarded the forts of Alexandria for over ten hours, July 11. On the two following days the town was sacked and plundered by the soldiery and populace, and great part of it destroyed by fire. A British force occupied it on the 14th.

The present city (called *Skanderi'eh* by the Arabs) is not situated exactly on the site of the old one, but is chiefly built on the mole, which has been increased by alluvial deposits till it has become a broad neck of land between the two harbours. The city is a strange mixture of East and West, old and new. The native town contains poor houses and wretched huts. The ever-increasing Frankish quarters have quite a European appearance, and swarm with cafés, shops, theatres, and the like. The chief square bears Mehemet Ali's name. Ramlah is a fashionable eastern suburb by the sea. The palace of Ras-el-Tin is the king's summer residence. The castle stands near the old Pharos, and the modern lighthouse has a revolving light, visible at a distance of 20 miles. Improvements have made the old harbour—the western one—one of the best and most spacious on the Mediterranean. The exposed eastern harbour or New Port has also been improved by the construction of an esplanade and breakwaters. There is railway communication with Cairo and Suez; the Mahmudia Canal, made by Mehemet Ali, connects Alexandria with the Nile. Pop. (1840) 60,000; (1882) 227,064; (1907) 332,246 (86,000 foreigners); (1917) 444,617. The value of exports (mainly cotton, cotton-seed, lentils, oilseed, hemp, drugs) reached in the early years of the 20th century over £30,000,000 a year (two thirds going to Britain); of imports, over £23,000,000 (two-fifths from Britain). Of objects of antiquity the most prominent is Pompey's Pillar (q.v.). The so-called Cleopatra's Needles (see OBELISK) long stood here. A funerary hypogeum was discovered in 1900 at the ancient stadium Kom-el-Shougafa. The Græco-Roman Museum has great archaeological interest. Near the town are catacombs and the recently unearthed ruins of the city of St Menas. The climate of Alexandria does not correspond with what is true of Egypt generally. In winter it rains almost daily; in summer the heat is moderated by sea-breezes.

ALEXANDRIAN CODEX, an important manuscript of the sacred Scriptures in Greek, now in the British Museum. It is written on parchment, in finely formed uncial letters, and is without accents, marks of aspiration, or spaces between the words. Its probable date is the middle of the 5th century. With the exception of a few gaps, it contains the whole Bible in Greek (the Old Testament being in the translation of the Septuagint), along with the epistles of Clemens Romanus, of whose genuine epistle to the Corinthians it is the only manuscript extant. For purposes of biblical criticism, the text of the Epistles of the New Testament is the most valuable part. This celebrated manuscript belonged, as early as 1098, to the library of the patriarch of Alexandria. In 1628 it was sent as a present to Charles I. of England by Cyrillus Lucaris, patriarch of Constantinople, who declared that he had got it from Alexandria, where he had held the same office; and that it was written there appears from internal and external evidence. Fac-similes have been published, of the New Testament, by Woide (Lond. 1786), and by Cowper (Lond. 1860); of the Old Testament, by Baber (Lond. 1816-28).

ALEXANDRIAN LIBRARY.—This remarkable collection of books, the largest of the ancient world, was founded by the first Ptolemy, and fostered by his son. It quickly grew, and already in the time of the first Ptolemy, Demetrius Phalereus had 50,000 volumes or rolls under his care. During its most flourishing period, under the direction of Zenodotus, Aristarchus of Byzantium, Callimachus, Apollonius Rhodius, and others, it is said to have contained 490,000, or, according to another authority, including all duplicates, as many as 700,000 volumes. The greater part of this Library, which embraced the collected literature of Rome, Greece, India, and Egypt, was contained in the famous Museum, in the quarter of Alexandria called the Brucheion. That during the siege of Alexandria by Julius Cæsar this part of the Library was destroyed by fire was a legend long believed to be historical; it is conjectured that a store of books for export was burned. The other part of the Library was kept in the Serapeum, the temple of Jupiter Serapis, where it remained till the time of Theodosius the Great. When this emperor permitted all the heathen temples in the Roman empire to be destroyed, the magnificent temple of Jupiter Serapis was not spared. A mob of fanatic Christians, led on by the Archbishop Theophilus, stormed and destroyed the temple, together, it is most likely, with the greater part of its literary treasures, in 391 A.D. It was at this time that the destruction of the Library was begun, and not at the taking of Alexandria by the Arabs, for the Khalif Omar, in 641, to which time its destruction is commonly assigned. A ridiculous, although ancient story, tells that the Arabs found a sufficient number of books remaining to heat the baths of the city for six months. The historian Orosius, who visited the place after the destruction of the temple by the Christians, relates that he then saw only the empty shelves of the Library. See Ritschl, *Die Alexandrinischen Bibliotheken*, in *Opuscula* (1866), and Weniger, *Das Alexandrinische Museum* (1875).

ALEXANDRIAN SCHOOL.—After liberty and intellectual cultivation had declined in Greece, Alexandria in Egypt became the home and centre of science and literature. The time in which it held this position may be divided into two periods; the first including the reigns of the Ptolemies, from 323 to 30 B.C.; the second, from 30 B.C. to 640 A.D. or from the fall of the Ptolemean dynasty to the irruption of the Arabs. During the first period the intellectual activity at Alexandria was mainly of a purely literary or scientific kind; but during the second, partly from Jewish and Christian influences, it developed into the speculative philosophy of the Neo-Platonists and the religious philosophy of the Gnostics.

Ptolemy Soter, the first ruler who introduced and patronised Greek science and literature in Alexandria, was followed by that yet more munificent patron, Ptolemæus Philadelphus, who regularly established the celebrated Alexandrian Library and Museum, which had been begun by his father. This Museum was somewhat like a modern university, and within its walls learned scholars both lived and taught. The loss of Greek freedom soon took from Greek thought much of its boldness and originality, but thinkers found substitutes for these in learned research and criticism. They studied grammar, prosody, mythology, astronomy, and medicine, and unfolded their information in long didactic poems in epic form, full of learning, and marked by perfect mastery of verse, but often dull to a degree, and marred by numerous obscure and recondite allusions. Examples of these are the *Argonautica* of Apollonius Rhodius, and the

Alexandra or *Cassandra* of Lycophron. Other writers of epics were Euphron, Nicander of Colophon, Dionysius, Dicearchus, Rhianus, and Oppianus. Many poets employed lyric and elegiac forms for subjects completely unsuited for poetic treatment, which are yet happily expressed in verse. The earliest of the elegiac poets was Philetas of Cos; the greatest, perhaps, Callimachus. Among the lyric poets were Phanocles, Hermesianax, Alexander of Ætolia, and Lycophron. Epigrams and dramas were also written; but of the latter scarce anything has survived beyond the names of the seven tragedians called the Alexandrian Pleiades. Out of the Amœbean verse or bucolic mime—a rudimentary kind of drama—grew the best product of Alexandrian poetry, the *Idylls* of Theocritus. Still more active than the poets were the grammarians, to whom it is mainly due that we now possess the masterpieces of Greek literature at all. They were both philologists and *littérateurs*, who explained things as well as words, and were thus a kind of encyclopædists. Among these the greatest were Zenodotus of Ephesus, Aristophanes of Byzantium, and Aristarchus of Samothrace; only less eminent critics were Alexander of Ætolia, Lycophron, Callimachus, and Eratosthenes. Their chief service consists in having collected the writings then existing, prepared corrected texts, and preserved them for future generations.

The Alexandrian school has a spirit and character altogether different from the previous intellectual life of Greece. From the attention paid to the study of language, it was natural that correctness, purity, and elegance of expression should be especially cultivated; and in these respects many of its writers are distinguished. But what no study and no effort could give—the spirit that animated the earlier Greek poetry—was in most of these works wanting. In place of it, there was displayed greater art in composition; what had formerly been done by genius, was now to be done by the rules furnished by criticism. Where imitation and rule thus took the place of inspiration, each generation of disciples became more artificial and lifeless than their masters, until ultimately criticism degenerated into frivolous fault-finding, and both prose and poetry became laboured affectation. Still, for about four centuries, the Alexandrian school was the centre of learning and science in the ancient world. Counting from its origin to its complete extinction, it lasted a thousand years. The influence of the Alexandrian school upon Latin literature in the Augustan age must not be forgotten. We find it in all the contemporary poets, notably in Virgil, the greatest poet of the group.

The ALEXANDRIAN PHILOSOPHY is characterised by a blending of the philosophies of the East and of the West, and by a general tendency to *eclecticism*, as it is called, or an endeavour to reconcile conflicting systems of speculation, by bringing together what seemed true in each. The most famous representatives of this school were the Neo-Platonists (q.v.). Uniting the religious notions of the East with Greek dialectics, they represent the struggle of ancient civilisation with Christianity; and thus their system was not without influence on the form that Christian dogmas took in Egypt. The amalgamation of Eastern ideas with Christian gave rise to the system of the Gnostics (see GNOSTICISM), elaborated chiefly in Alexandria. See Bigg's *Christian Platonists of Alexandria* (Bampton Lectures, 1886); and the articles PHILO JUDEUS, CLEMENS ALEXANDRINUS, ORIGEN.—The Alexandrian school was no less distinguished for the culture of the mathematical and physical sciences, which here reached a greater height than anywhere else in

ancient times. Its mathematical school was founded in the reign of the first Ptolemy by the famous Euclid. Among its chief ornaments were Eratosthenes, who wrote well on almost all branches of human knowledge. His works on chronology are still valuable, and he was the first to attempt the measurement of the earth. Another was Apollonius of Perga, 'the great geometer,' author of a work on conic sections. The astronomers were distinguished from all their predecessors by their setting aside all metaphysical speculation, and devoting themselves to strict observation. Perhaps the greatest was Hipparchus, the true father of astronomy, to whom Claudius Ptolemy owed the substance of his famous work, the *Almagest*.

Alexandria, a town of Dumfriesshire, on the west bank of the Leven, opposite Bonhill, 3 miles N. of Dumfries. It has grown from a mere 'clachan' to a thriving town, such growth being due to the neighbouring cotton-printing, bleaching, and Turkey-red dye-works, established since 1768. Pop. 6000.

Alexandria, a port of entry on the right or Virginian bank of the Potomac, U.S., 7 miles below Washington, on the opposite side of the river, with which it is connected by rail. Though Alexandria is fully 100 miles from the entrance of the Potomac into Chesapeake Bay, yet the stream in front of it, which forms its harbour, is still a mile wide. The place is accessible from the sea to the largest vessels, and has ample railway accommodation; the Chesapeake and Ohio canal begins here. There are some cotton manufactures. In Old Christ Church Washington's pew is still pointed out. Pop. 18,000.

Alexandrina, LAKE. See MURRAY RIVER.

Alexandrines are rhyming verses consisting each of twelve syllables or six measures. The name is most probably derived from an old French poem on Alexander the Great, composed between 1180 and 1190, in which this measure was first used; according to others, it was so called from the name of one of its authors, Alexander de Bernay. The Alexandrine has become the regular epic or heroic verse of the French, among whom each line is divided in the middle into two hemistichs, the sixth syllable always ending a word. In English, this rule is not always observed, as in the following verse:

That all the woods shall an | swer, and their echoes r.e.g.

The only considerable English poem wholly written in Alexandrines is Drayton's *Polyolbion*; but the Spenserian stanza regularly ends in an Alexandrine, and the measure occurs occasionally in our common heroic verse of five feet, as the last line of a couplet:

When both are full, they feed our blest abode,
Like those that watered once | the paradise of God.—DRYDEN.

Pope's lines in the *Essay on Criticism* are familiar:

A needless Alexandrine ends the song,
That, like a wounded snake, drags its slow length along.

In spite of this, Pope introduced Alexandrines at the close of his *Messiah* and elsewhere, though his later poems contain very few examples. According to Dr Johnson, 'Cowley was the first poet that mingled Alexandrines at pleasure with the common heroic of ten syllables; and from him Dryden borrowed the practice, whether ornamental or licentious.'

Alexandropol (formerly *Gumri*), an important fortress and the largest town in the Eivan district of Armenia, on a treeless plateau on the road from Erivan to Kars, has accommodation for a garrison of 10,000 men. The stronghold gave the Russians complete command of the head-waters of the Euphrates; the place, the scene of much fighting, was theirs from 1853. The silk trade is actively carried on. Pop. 50,000.

Alexandrovsk, a small town of Ukraine, on the left bank of the Dnieper, 202 miles N. of Simferopol by rail; pop. 20,000. See also KOLA.

Alexei, or **ALEXIS**, called **MIKHAILOVICH**, the second Russian tsar of the House of Romanov, was born in 1629, and succeeded his father, Michael, in 1645. An insurrection disturbed his reign in 1648, and popular discontent favoured the plans of two pretenders to the throne. In his two campaigns against the Poles (1654-67) he took Smolensk, conquered and devastated almost the whole of Lithuania, and secured for himself the possession of several provinces. He also gained a part of the Ukraine; but his war with Sweden (1656-58) was unfortunate. Alexei introduced various important reforms into the Russian laws, and ventured on some ecclesiastical changes which produced serious dissensions. He died in 1676. By his second wife he was the father of Peter the Great.

Alexei, called **PETROVICH**, the eldest son of Peter the Great of Russia, was born at Moscow in 1690. Opposed to Peter's innovations, he was excluded from the succession to the throne, but escaped to Vienna, and thence went to Naples. He was induced to return to Russia, and soon after the accomplices of his flight were punished with merciless severity. In 1718 Alexei himself was placed on trial and condemned to death, but two days later died, as was probably intended, from the effects of his examination under torture. Other accounts assert that he was beheaded in prison. His son, as Peter II., was elevated to the throne.

Alexeiev, **MIKHAIL VASILEVICH** (1857-1918), Russian general, son of a private soldier, served in the Russo-Turkish war and (as Quarter-master-general of the Third Army) in the Russo-Japanese war, and lectured on strategy. In the Great War (q.v.) as Chief of Staff he directed the offensive in Galicia and the retreat from Warsaw. Virtually Commander-in-chief under Kerensky, he mediated in the Kornilov affair, then resigned, and taking up arms against the Bolsheviks, was defeated, and died of pneumonia.

Alexinatz, a town of Serbia, on the Moravitz, 134 miles SSE. of Belgrade by rail. In 1876 it suffered severely on its capture by the Turks; and near it is a memorial (1880) to the Russians who fell there. Much tobacco is raised in the neighbourhood. Pop. 10,000.

Alexius Comnenus (1048-1118), one of the ablest rulers of the Byzantine empire, was born at Constantinople. He was the nephew of the Emperor Isaac Comnenus, on whose abdication, in 1059, Alexius's father refused the purple. Alexius, having in youth given brilliant promise of military genius, was at length, in 1081, after four brief anarchic reigns, elevated by his soldiers to the throne. Gibbon graphically paints his position and achievements. Everywhere he was encompassed with foes. The Scythians and Turks were pouring down from the north and north-east; the fierce Normans, who had effected a lodgment in Sicily and Italy, were menacing his western provinces; and, in 1096, the myriad warriors of the first crusade burst into his empire on their way to Palestine, and encamped around the gates of his capital. Yet he contrived to avoid all perils by the wisdom of his policy, the mingled patience and promptitude of his character, his discipline in the camp, and his humanity on the throne. He reigned for thirty-seven years; and had it been possible to preserve the weak and corrupt Byzantine empire in its integrity, a ruler like Alexius might have achieved the task. He could only delay the inevitable doom. Historians differ as to the sincerity of his conduct towards the crusaders. His daughter Anna Comnena, who wrote his life, defends his 'policy' with

filial piety; but it seems clear that he entertained a profound dread and suspicion of the half-civilised Franks, and, knowing the weakness of his own empire, was compelled to dissimulate.

Alfa, also spelt *Halfa*, is one of the varieties of Esparto (q.v.).—**ALFALFA** is the Spanish and Spanish-American name for Lucerne (q.v.).

Alfarabi, an Eastern philosopher, born at Farab, across the Oxus. After studying at Bagdad, he travelled widely, and, on finally settling at Damascus, he was received with honour by the khalif, who assigned him a pension, which he enjoyed till his death in 950. He led a life retired and temperate, almost ascetic. The subjects of his voluminous writings embrace almost every known science; but he is most worthy of remembrance for his work in the compilation of an Encyclopædia, the MS. of which is in the library of the Escorial.

Alfieri, **VITTORIO**, COUNT, one of the most famous of modern Italian poets, was born at Asti, in Piedmont, on the 17th January 1749. His education was very defective, but at fourteen he found himself master of a vast fortune. The chief interest of his youth was a passionate love for horses, which he retained through life. The years 1767-72 he spent in travelling through the greater part of Europe, after which he returned to Turin, and devoted himself to literary pursuits, renouncing idleness and unworthy amours. The applause which his first attempts received, encouraged him in his determination to win fame as a dramatic author. But as he clearly saw the deficiencies of his education, he began at a mature age to learn Latin, and also to study the Tuscan dialect, for which purpose he went to Tuscany. In Florence (1777) Alfieri made the acquaintance of the Countess of Albany, wife of the Pretender, Charles Edward Stuart. He became deeply attached to her, and in this—the one persistent love of his life—he found the impulse that his vacillating nature needed. To render himself worthy of her esteem, he strove with unrelenting earnestness after poetic excellence; and in order to be perfectly free and independent of all other cares, he transferred his whole property to his sister, in exchange for an annuity which was hardly half his former income. He now lived alternately in Florence and in Rome, latterly with the Countess; and after the death of her unworthy husband, they lived together in Alsace or in Paris, until the Revolution drove them first to England, and next to Florence. Here Alfieri died, on the 8th October 1803. Their ashes repose in the church of Santa Croce, in Florence, under a beautiful monument by Canova, between the tombs of Michelangelo and Machiavelli. Alfieri published twenty-one tragedies, six comedies, and one 'tramelogedia'—a name invented by himself. These show a want of fresh imaginative vigour, and betray the laborious perseverance with which their author did violence both to himself and to art. He was inspired more by politics than by poetry. He wished to breathe a spirit of freedom into the dormant minds of his countrymen, and considered the theatre as a school in which the people might learn to be 'free, strong, and noble.' In order to preserve the purity of his muse, Alfieri had resolved to read no other Italian poet. He wished to produce an effect by the very simplest means, and, renouncing the aid of ornament, to please by manly strength and earnestness alone. His works are on this account cold and stiff, his plots simple even to poverty, his verse hard and unpleasing, and his language destitute of that magic splendour of colouring which stirs the inmost soul. In spite of this, Alfieri did good service to

Italian tragedy. He corrected the effeminate taste which had before prevailed, as well as the pedantry of an affected imitation of Attic models. Succeeding writers endeavoured to imitate his strength and simplicity. His comedies are less successful than his tragedies. They manifest the same serious political tendency; the invention is poor, the development of the plot uninteresting, and the characters are only general sketches, without individuality. The most successful of his dramatic works is his 'tramelogedia' *Abele*, a mixture of tragedy and opera. Besides his dramatic works, he left an epic poem in four cantos, an autobiography, also many lyrical poems, sixteen satires, and poetical translations of Terence, Virgil, and portions of Æschylus, Sophocles, Euripides, and Aristophanes.

Vaughan in *Types of Tragic Drama* (1908) praises him for having under an austere classical form secured in his tragedies a rare intensity of action and passion, and characters drawn with subtlety and vividness. See also Vernon Lee's *Countess of Albany* (1884).

Alfonso III., surnamed THE GREAT, king of Leon, Asturias, and Galicia, succeeded his father, Ordoño, in 866. After reducing to obedience his jealous and factious nobles, he turned his arms against other enemies, fought through more than thirty campaigns and gained numerous victories over the Moors, occupied Coimbra, and extended his territory as far as Portugal and Old Castile. But these constant wars entailed great expense and misery on his subjects, and resulted, in 888, in a popular rising, at the head of which was Alfonso's own son Garcias. But the active king quickly crushed the rebels, and threw his son into prison. A second conspiracy, instigated by the queen, was more successful, and Alfonso was obliged to abdicate the throne, and divide his territory among his three sons. But once again the old hero was called upon to save his country, and lead its armies against the invading Moors. After returning in triumph, he died at Zamora, 910.

Alfonso X., surnamed 'the Astronomer,' 'the Philosopher,' or 'the Wise' (*El Sabio*), king of Leon and Castile, born 1226, succeeded his father, Ferdinand III., in 1252. Elected as their king by part of the German princes in 1257, he had to be content with the empty honour, nor was he more successful in his hereditary claim to Swabia through his mother Beatrix, daughter of Philip of Swabia. He was more successful in his wars with the Moors, and his victories over them enabled him to unite Murcia with Castile. In 1271 he was able to crush an insurrection headed by his son Philip; but a second and successful rising, under another son Sancho in 1282, deprived him of his throne. Two years later, he died a fugitive at Seville. Alfonso was the founder of a Castilian national literature. He caused the first general history of Spain to be composed in the Castilian tongue by his historians, as well as a translation of the Old Testament to be made into the vernacular by Toledo Jews. He completed the well-known code of laws, *Leyes de las Partidas*, which in 1501 became the universal law of the land; and he wrote several long poems, besides a work on chemistry, and another on philosophy. He sought to improve the Ptolemaic planetary tables, whose anomalies had struck observers even at that early time. For this purpose, he assembled at Toledo upwards of fifty of the most celebrated astronomers of that age. His improved planetary tables, still known as the *Alfonsine Tables*, were completed in 1252 at the cost of 40,000 ducats. The *Opusculos Legales* of Alfonso were published by the Royal Academy of Madrid in 1836.

Alfonso I. (*El Conquistador*, 'the Conqueror'), earliest king of Portugal, was the son of Henry of,

Burgundy, conqueror and first Count of Portugal. Born in 1110, he was but two years of age at his father's death, so that the management of affairs fell into the hands of his ambitious and dissolute mother, Theresa of Castile. Wrestling the power from her in 1128, he turned his sword against Castile and the Moors, and defeated the latter, after a bloody struggle, at Ourique, July 25, 1139, proclaiming himself king of Portugal on the field of battle. The title was confirmed by the pope three years later. After settling the succession, the privileges of the nobility, and the administration of justice at the Cortes of Lamego, with the help of some casual English crusaders he took Lisbon (1147), and later, the whole of Galicia, Estremadura, and Elvas. He died at Coimbra, December 6, 1185.

Alfonso VI., king of Portugal, succeeded his father, John IV., in 1556, when but thirteen years of age. For some years the government was in the hands of his mother, Luise de Guzman, a woman of great wisdom and prudence; but in 1662 the sickly and dissolute prince dismissed his mother from her office, only to fall as completely into the hands of his minister, Count Castel-Melhor. Yet Portugal was victorious in the war against Spain, spite of the incapacity of king and minister, although for this she had to thank her English and French allies. In 1666 Alfonso married a princess of Savoy, but the queen was soon disgusted with her unworthy husband, and conspired with his brother Pedro against him. He was forced to surrender to the latter his crown, and to dissolve on his behalf what was a marriage merely in name. Alfonso died twelve years later (1683), a state prisoner at Cintra.

Alfonso V., king of Aragon and Navarre, but Alfonso I. of Naples and Sicily, 'the Magnanimous,' succeeded his father in 1416, when but 15 years old. Summoned to her help by Queen Joanna II. of Naples, he defeated her foes, Sforza and Louis of Anjou, but lost her favour by throwing into prison her minion Caraccioli. The fickle queen now declared his rival Louis her successor. At her death in 1435, Alfonso resolved to claim the kingdom, but found himself opposed by Duke René of Lorraine, whom Joanna had appointed her successor after the death of Louis. Rome and Genoa sided with René, and the Genoese fleet attacked and defeated that of Alfonso, the monarch himself being taken prisoner. He was sent to Duke Philip of Milan, who, charmed by his manner and talents, soon set him at liberty, and even formed an alliance with him. After a five-years' warfare, Alfonso was successful, and entered Naples in triumph, and was recognised as its king by the pope. He patronised letters and the arts, and governed with prudence and justice. He died at Naples in 1458, leaving his hereditary dominions to his brother John, and Naples to his own son Ferdinand, who was legitimised by the pope.

Alford, a village of Aberdeenshire, 30 miles NW. of Aberdeen. Here Montrose defeated the Covenanters under Baillie, 2d July 1645.

Alford, HENRY, born in London in 1810, studied at Trinity College, Cambridge, and in 1835-53 was vicar of Wymeswold, Leicestershire. His *Poems and Poetical Fragments* (1831) was followed by *The School of the Heart, and other Poems* (1835), *Chapters on the Greek Poets* (1841). In 1844-61 appeared in 4 vols. his *magnum opus*, the Greek Testament, with notes and various readings. From 1853 at Quebec Chapel, London, he maintained his reputation as a preacher, and in 1857 he was appointed Dean of Canterbury. *A Plea for the Queen's English* (1863) was one of his 48 volumes. He was the first editor (1866-70) of the *Contemporary Review*. Several of his hymns are widely

popular. He died January 12, 1871. See the Life by his widow (1873).

Alfred (or **ÆLFRED**), king of Wessex in 871-901, well deserves his cognomen of 'the Great,' though his kingdom was small, his military power barely enough for his needs, and his character eminent rather for manly strength, sagacity, and the kingly sense of responsibility than for military or literary genius. So revered was he by contemporaries and later ages that his actual achievements were overgrown by fable—such as the stories of his visiting the Danes' camp disguised as a harper, and of his neglecting the cakes of the cottager's wife. The translation of Bede's history was not his, though he probably had it made. His services to England and to English culture are noticed under **ENGLAND** and **ENGLISH LITERATURE**. Alfred was born at Wantage in 849. His father was Ethelwolf, son of Egbert, king of the West Saxons; and though the youngest of five sons, he succeeded to the crown, in 871, on the death of his brother Ethelred, at the age of 22. By that time the Danes had overrun most of England north of the Thames. The victory of Ashdown, won chiefly by the bravery of Alfred, before his accession to the throne, had given only a temporary check to their incursions into Wessex. In the year of his accession, the West Saxons fought nine battles against the Danes, with varying success. After that there was respite for several years, till, early in 878, Guthrum, king of the Danes of East Anglia, suddenly burst into Wessex with his savage host. Alfred could make no effectual resistance, and had to seek refuge in the marshes of Somersetshire. There he raised a fort at Athelney, and with a band of faithful followers maintained himself for several months. To this period belongs the well-known story of the burnt cakes. The West Saxons, however, were not subdued. In the same year (878), Alfred gathered his friends around him, and defeated the Danes at Edington, in Wiltshire. By the Peace of Wedmore, Guthrum was obliged to receive baptism, and to acknowledge the supremacy of Alfred, who retained for himself the country south of the Thames, and the greater part of Mercia, while ceding to the Danes East Anglia and the rest of Mercia. The wisdom of the arrangement is seen in the fact that Guthrum, on the whole, continued quiet and faithful to the treaty till his death.

Early in his reign, Alfred saw the necessity of meeting the Danes on their own element, the sea, and his success led him to establish an English navy. In 886 he recovered London, in 893 Northumbria made submission to him; and thus he became nominally king of all England. On the whole, Alfred enjoyed a much-needed period of peace, from the Peace of Wedmore (878) till 893, when a fresh swarm of Danes, under the leadership of Hasting, infested the country. They were supported by their fellow-countrymen in East Anglia and Northumbria, and gave much trouble. At last, in the course of their marching and ravaging, they sailed with their fleet up the Lea, where Alfred brought them to terms by diverting the river, and leaving their ships dry. After five years of struggle, peace was re-established.

As a leader, Alfred's great work thus consisted in repelling the invasion of the Danes, who at his accession threatened to subdue the whole country, and in helping towards the consolidation of England into a united monarchy. His work as a legislator is also important, though it is absolutely unhistorical to regard him as establishing trial by jury, as having divided England into counties and hundreds, or as the founder of the university of Oxford. As legislator, he simply compiled or collected the best among the enactments of earlier

kings. The aim of all his work was practical, to promote the good of his people; and the writings for which he is celebrated bear the same character of sagacious usefulness.

Alfred died on the 27th of October 901, aged 52, leaving his country in the enjoyment of comparative peace and prosperity, the fruit of that wise and energetic rule which has made his memory dear to all generations of Englishmen, as that of their best and greatest king. We cannot perhaps realise the resolute patience of Alfred in his political and military capacity, for we have but a very imperfect knowledge of the obstacles which stood in his way; but it must excite both our highest wonder and reverence to behold a man pursuing solitarily, in the midst of ferocity, barbarism, and ignorance, and in spite of the perpetual pains with which his body was racked, so many various and noble schemes for the civilisation and true glory of his country. The principal writings of Alfred are his translations of Boethius' *Consolation of Philosophy*, of the Histories of Bede and Orosius, and of the *Pastoral Care* of Gregory the Great (the last edited by Sweet, 1871). By Layamon Alfred is called 'Engelondes deorling;' and Freeman declares, 'There is no other name to compare with his; he is the most perfect character in history.'

Asser (q.v.) and the chronicles are the old authorities. There are Lives by Paul (trans. 1858), Hughes (1878), Lees (1919); and the millenary of his death produced numerous memorial works—by Oman, Earle, Pollock, and others (1899), Conybeare (1914), F. Harrison (1901), Sir W. Besant (1901). But by far the most authoritative is *Alfred's Life and Times*, by C. Plummer (1902).

Alfreton, an urban district of Derbyshire, 14 miles NNE. of Derby by rail, with manufactures of stockings; pop. 20,000.

Algæ. While the sea-weeds furnish the most familiar representatives of this great series of lower plants, many forms are abundant in fresh water, and even occur on *terra firma*. So great is the diversity of form which they present, that they must by no means be regarded (as was too long the case) as a 'mere natural order,' corresponding to those of higher plants, but rather as a vast and vague alliance comprehending many orders, and presenting all degrees of organisation, from the simple and almost undifferentiated cell, onwards through linear and plane cell-aggregates, to forms of almost arborescent complexity and often gigantic size. It is impossible, therefore, to indicate any set of common characters corresponding to those presented by higher groups: the real diagnosis must be rather a negative one. Dividing the vegetable kingdom into (a) *Cormophytes*, characterised by the possession of an ascending and descending axis, with appendages, and comprehending the higher cryptogams as well as the phanerogams; and (b) *Thallophytes*, destitute of stem and leaf—the latter are broadly distinguishable as Algæ, Fungi, and Lichens. The Lichens (q.v.) being analysed into a curiously interwoven web of mixed algal and fungal nature, the problem of discriminating algæ from fungi remains, and this has been the subject of no little research and controversy (see **FUNGI**). The essential fact, however, is, that in both groups there is exhibited a broadly parallel advance in morphological complexity, from unicellular and filamentous to higher forms, and similarly as respects the reproductive system. These correspondences are, moreover, sometimes so close as to leave little doubt of the origin of the fungal form from the corresponding algal one, by the simple disappearance of its chlorophyll, consequent on the assumption of parasitic or saprophytic life, just as is observed among phanerogams, such as dodder or toothwort. The presence or absence of chlorophyll becomes thus

the only almost constant distinction between fungi and algæ, and this break-down of the morphological barrier led Cohn, and subsequently Sachs and other botanists, to frame classifications in which the fungi and algæ were arranged together in a single ascending series, characterised by the degree of differentiation of the reproductive system. A summary of this mode of classification is thus worth noting, not only because it has been extensively employed in botanical manuals, &c., but because emphasising the importance of the degree of development of the reproductive system. (1) Reproduction asexual—PROTOPHYTA. (2) Reproduction by conjugation of similar cells to form a resting 'zygospore'—ZYGOSPOREÆ. (3) Reproductive cells distinctly differentiated as male and female; the fertilised female cell (ovum) giving rise to swarmspores or a new plant—OOSPOREÆ. (4) After fertilisation, a peculiar vegetative growth arises, within which the fertilised ovum may variously develop—CARPOSPOREÆ. The defects of such a classification, both in grouping quite unrelated forms and separating obviously kindred ones, have been long ago and fully pointed out, especially by De Bary; and for the present purpose it will be convenient to waive as far as possible the dogmatic treatment of the problem of classification, and above all things clearly to point out the general lines upon which all classifications are based, and the essential facts which these differ merely in variously accenting. A series of the most important and accessible of the simpler types of algæ must, in the first place, be briefly described.

Our concrete studies may therefore conveniently commence with such a simple and common form as the *Pleurococcus vulgaris*, to which the green

Fig. 1.—Life-history of Unicellular Plant (*Pleurococcus*): 1, encysted, 2, cutting its wall, 3, ciliated; 4, quiescent; 5 and 6, dividing.

covering of tree trunks, &c. is largely due. Here the organism is a simple Cell (q.v.), or nucleated mass of protoplasm, tinged green by chlorophyll, and covered by a cellulose wall. Multiplication by transverse division is, however, in active progress; twos and fours are thus formed, but soon separate as independent cells. Closely allied forms occur in water, and may be followed through a more complex life-history. Especially after a period of cold or drought, the remarkable process of 'rejuvenescence' may be observed: the protoplasm escapes through a rupture in the cell-wall, develops a couple of delicate contractile filaments or cilia, and thus enters an actively 'motile stage' of existence. After a time the resting phase is resumed, the cilia being withdrawn, and a cell-wall redeveloped.

Some such forms are known in the vegetative state alone, and where simply green, are termed *Palmellaceæ*; they frequently have gelatinous cell-walls. Many doubtfully allied types develop bluish or yellowish chlorophyll (phycoeyan and phycoxanthin of spectroscopists; and are hence united under the common title of *Cyanophyceæ*. Some of these form jelly-like masses (*Glæocapsa*, *Nostoc*), others become filamentous; the constituent cells of the filament remaining similar to each other (*Oscillatoria*), or differentiating a larger cell, or 'heterocyst' of dubious function, generally at one end (*Rivularia*). The chlorophyll, too, may disappear altogether, and then we pass almost insensibly among the *Bacteria* or *Schizomycetes*. These

lowest algæ, in which multiplication is by transverse division only, may therefore more con-

Fig. 2.

A, *Nostoc*; B, *Oscillatoria*; C, *Rivularia*.

veniently be discussed along with their more important congeners, the *Bacteria* (q.v.).

Returning to our primitive Protococcus-like form, we may readily imagine its multiplication by division to continue until not only four, but eight, sixteen, or more segments are formed. Let these segments, held together by a slightly more gelatinous cellulose envelope, pass into the motile phase, the result will be a ciliated sphere, of which the constituent cells may sometimes themselves re-segment before breaking up; more frequently, however, they separate, and may often be observed

Fig. 3.

A, Life-history of *Chlamydomonas*, showing encystment with division, liberated zoospores, conjugation of equal and of unequal zoospores; B, *Pandorina*; C, *Eudorina*; D, *Volvox*. (The arrows indicate the recommencement of the cycle by the resting spore or ovum.)

uniting or 'conjugating' in pairs to form a single cell, which, after a period of rest, divides and repeats the cycle anew. Such a form with eight segments is *Chlamydomonas*; with sixteen segments, *Pandorina*. Among such forms, a differentiation of the conjugating cells becomes increasingly obvious, until the primitively equal and similar 'zoospores' become distinctly larger and smaller—macro- and microspore respectively; we have, in short, the dawn of sex. Vegetative progress also continues; the segmentation mass may increase to thirty-two or sixty-four, and after a brief period of agitation, may settle into a beautifully stellate figure like *Pediastrum*, or may even continue dividing till

many thousand minute cells are formed, which, on settling, elongate, and apply themselves point to point, so as to form a network of loose meshes (*Hydrodictyon*). Macrospores and microspores are here well distinguished; we have still, however, to seek for the full differentiation of sex. This occurs in such a form as *Volvox*, where the segmentation mass forms a beautiful spherical layer of ciliated cells, connected by protoplasmic bridges, and embedded in a gelatinous matrix of undistinguishable cell-wall substance. After the vegetative growth has passed its climax, some cells begin to grow at the expense of others; of these, many become ova, while others, after a time, segment into tiny spermatozoa (for the familiar animal names of the essential sex-cells may be fairly applied). Fertilisation takes place in the usual way, and is followed by the segmentation of each ovum into a new colony.

But instead of the simple spherical segmentation of *Pandora* or *Chlamydococcus*, which we may trace to the division in planes at right angles seen in *Protococcus* (fig. 1), we may have the successive planes of division remaining parallel. Such successive divisions in parallel planes will produce a filament, and, as we have seen above, we thus enter among a vast new series of forms. The simplest of

ductive system is, however, still more remarkable; many species are constantly dioecious; the dwarfed male filaments grow on the larger female ones; spermatozoid and ovum respectively develop, with separation of portions recalling the sperm-cap and polar vesicle of animals, or the distinction of vegetative and reproductive nucleus demonstrated by Strasburger in the pollen grain (see OVUM).

The remarkable and varied *Desmidiæ* and *Diatomaceæ*, so familiar to microscopists, though rarely filamentous, have been regarded, on account of their habit of conjugation, as allied to the *Mesocarpeæ*; but since they are on many grounds entitled to separate and fuller treatment, their structure and affinities need not here be discussed (see DESMIDS, DIATOMS).

Branching occurs at various points in this filamentous series, and this readily leads us to the formation of bi-dimensional (flat) cell-aggregates, such as the common green *Ulva* of every sea-shore. Here we start afresh with rejuvenescence by swarm-spores, capable of reproducing the parent plant without conjugation; in higher genera at least (*Enteromorpha*), conjugation occurs, and macrospore and microspore are distinguishable; while the change from a plane to a tubular arrangement of cells in *Enteromorpha* leads us to solid or tridimensional forms.

Before entering, however, on the study of these complex multicellular forms, we should return to note the unexhausted possibilities of unicellular differentiation. Hitherto we have examined different modes of cell-division, but we may imagine the necessity of this superseded by the continuous growth and regional differentiation of the primitive cell. Such a form is commonly presented us by the remarkable *Botrydium*, not uncommon in greenhouses (fig. 5, C). Here the cell elongates vertically, without division, into what is curiously analogous to the ascending and descending axis of a higher plant. The upper portion remains above ground, expands, and vegetates; the lower divides into colourless processes, which perform both the mechanical and absorptive functions of roots. Multiplication may take place by simple lateral gemmation, or by other methods, varying

Fig. 4.

A, Life history of *Ulothrix*; B, of *Mesocarpus*; C, *Spirogyra*, D, *Edogonium*.

these, as already stated, merely vegetate indefinitely, with periods of repose, without showing any signs of conjugation or the sexual process. In many filamentous algae the process of rejuvenescence occurs, and the zoospores may conjugate; in the lowest of which conjugating forms the zoospores are equal and similar, but the differentiation of macrospore and microspore soon arises (*Ulothrix*). Again, the motile phase may entirely disappear, and conjugation without rejuvenescence take place between the cells of parallel filaments: here, as formerly, equality and similarity may be perfect (*Mesocarpus*); or incipient sex may manifest itself (*Spirogyra*); finally, sex may become perfected (*Sphaeroplea*). Yet a further specialisation is possible: the reproductive changes may be restricted to definite cells or portions of the filaments; and such a case is afforded by *Edogonium*. This peculiar form is characterised, so far as its vegetative system is concerned, by the peculiar specialisation for the opening and the repair of that (in other forms irregular) rent of the cell-wall which is necessary for rejuvenescence. The repro-

Fig. 5.

A, *Caulerpa*, B, *Bryopsis*, C, *Botrydium*, D, *Vaucheria*.

widely with the conditions of the environment. In ordinary circumstances, when moisture is abundant, the protoplasmic contents simply break up into zoospores, which, on settling down with or without conjugation, reproduce the plant. Under the influence of drought and sun, the protoplasm descends into the root filaments, and there encysts itself, rejuvenescence by-and-by taking place as usual; while, on the approach of winter, the encystment takes place with the upper vegetative portion of the cell, which becomes gradually thickened. Another very interesting allied form is *Vaucheria*

(fig. 5, D). Here the cell lengthens into a filament, and distinct male and female organs differentiate from short lateral branches, true sexual fertilisation occurring. In some species, however, all the less differentiated modes of reproduction have been observed; thus in *Vaucheria sessilis*, a many-ciliated zoospore is formed, which is active for hours; in another (*V. sericea*), this is only active for a few minutes, and in *V. geminata* it never issues at all, but simply rejuvenesces without leaving its cell-wall, like a pollen grain; finally, the quiescent bud simply drops off (*V. tuberosa*), to germinate into a new filament. The marine types start with simple forms—*Valonia* recalling *Botrydium*, as *Codium* does *Vaucheria*—but assume a high degree of vegetative complexity, e.g. the branched *Bryopsis*, and at length the (multicellular) *Acetabularia*. With this increase of vegetative differentiation, the converse reproductive degeneration is beautifully illustrated. Thus the former still multiplies by zoospores which conjugate, but those of the latter simply rejuvenesce, and the plant is more frequently reproduced by vegetative buds; while in the enormously ramified and complex, but still unicellular *Caulerpa*, the mode of multiplication seems to be reduced to occasional gemmation from the relatively less vegetative root portion alone.

We have now surveyed the families of lower algae, and have seen that the degree of differentiation of the reproductive process in the direction of definite sex runs broadly parallel, while the vegetative structure is much more widely differentiated. It is therefore rather by the latter that we must especially classify, and, without insisting on a too rigorous application of this principle, it is evident (1) that, as has long been increasingly obvious, the *Palmellaceae* represent, or, at anyrate, include largely the vegetative states of higher forms; (2) that the *Protococcaceae*, *Pandorineae*, *Hydrodictyceae*, and *Volvocineae* form another natural series, characterised by their mode of cell-division and aggregation; (3) that the simple confervoid types lead to *Ulvaceae* on one hand, and to *Chetophoraceae*, *Ulothrichaceae*, &c., on others, the *Conjugatae* being also not very far remote; while (4) the *Siphonae*, despite the necessary parallelism of their reproductive evolution, represent an exceedingly distinct and lower type of structure, which separates them from all the algae proper.

The brown seaweeds (*Phaeophyceae*, *Fucaceae*) and the red seaweeds (*Florideae*) are of much greater complexity, both vegetative and reproductive, than any of the preceding forms, and may conveniently receive separate treatment (see SEA-WEEDS).

Algardi, ALESSANDRO, born at Bologna in 1602, ranks next to Bernini among Italian sculptors of the 17th century, and excelled especially in the representation of the nude. His works, however, suffered from a striving after picturesqueness, opposed to the simplicity of true sculpture. The most important is a colossal relief, in St Peter's, of 'Pope Leo restraining Attila from marching on Rome.' Algardi died in 1654.

Algaroba. See CAROB.

Algarotti, FRANCESCO, an Italian author, was born at Venice in 1712, studied in Rome and Bologna, and in his twenty-first year visited Paris, where he published *Newtonianismo per le Donne* (1733), the basis of his subsequent reputation. Until 1739, he lived in France. On his return from a journey to Russia, Algarotti became acquainted with Frederick the Great, who in 1740 made him a count; in 1747, chamberlain. Patronised also by Augustus III. of Poland, he lived alternately in

Berlin and Dresden until 1754, when he returned to Italy. He died March 3, 1764, at Pisa, where Frederick raised a monument to his memory. His reputation as a connoisseur is confirmed by his *Saggi sopra le Belle Arti*, and by the paintings he selected for the Dresden Gallery. His poetry displays no great genius; but his letters rank with the best in the Italian language. There is a good edition of his works in 17 vols. (Venice, 1791-94).

Algarvé, the smallest and most southerly of the provinces of Portugal. The name is Arabic, and means 'a land lying to the west.' It was a Moorish province till 1253. Its area is 1900 sq. m. and its population over 270,000. The northern part of the province is occupied by a range of barren mountains of an average height of 4000 feet, terminating in Cape St Vincent; and the country slopes southward to the narrow level tract along the coast. The plain, unsuitable for grain, produces abundance of fruit and wine. The inhabitants employ themselves chiefly in fishing, in manufacturing salt, and in cultivating fruit. The chief town is Faro.

Algazali. See GHAZALI.

Algebra is a branch of pure mathematics. The name is derived from the Arabs, who call the science *Al jebr wa'l muqabalah* ('redintegration and equation'). The term algebra is generally used to denote a method of calculating by means of letters which are employed to represent the numbers, and signs which are employed to represent their relations. Literal arithmetic, then, or multiplying, dividing, &c. with letters instead of Arabic ciphers, is properly only a preparation for algebra; while Analysis (q.v.), in the widest sense, would embrace algebra as its first part. Algebra itself is divided into two chief branches. The first treats of Equations (q.v.) involving unknown quantities having a determinate value; in the other, called the Diophantine or Indeterminate Analysis, the unknown quantities have no exactly fixed values, but depend in some degree upon assumption.

The oldest work in the West on algebra is that of Diophantus of Alexandria, in the 4th century after Christ. It consisted originally of 13 books, and contained arithmetical problems; only six books are now extant. They are written in Greek, and evince no little acuteness. The modern Europeans got their first acquaintance with algebra, not directly from the Greeks, but, like most other knowledge, through the Arabs, who derived it, again, from the Hindus. The chief European source was the work of Mohammed ben Musa, who lived in the time of Khalif Al Mamun (813-833); it was translated into English by Rosen (1831). An Italian merchant, Leonardo Bonaccio, of Pisa, travelling in the East about 1200, acquired a knowledge of the science, and introduced it among his countrymen on his return; he left a MS. work on algebra. The first work on algebra after the revival of learning is that of the Minorite friar Paciolo or Luca Borgo (Ven. 1494). Scipio Ferreo in Bologna discovered, in 1505, the solution of one case of cubic equations. Tartalea of Brescia (died 1557) carried cubic equations still further, and imparted his discoveries to Cardan of Milan as a secret. Cardan extended the discovery himself, and published, in 1545, the solution known as 'Cardan's Rule.' Ludovico Ferrari and Bombelli (1572) gave the solution of biquadratic equations. Algebra was first cultivated in Germany by Christian Rudolf, in a work printed in 1524; Stifel followed with his *Arithmetica Integra* (Nümb. 1544). Robert Recorde in England, and Pelletier in France, wrote about 1550. Vieta, a Frenchman (died 1603), first made the grand step of using

letters to denote the known quantities as well as the unknown. Harriot, in England (1631), and Girard, in Holland (1629), still further improved on the advances made by Vieta. The *Géométrie* (1637) of Descartes makes an epoch in algebra; it is rich in new investigations. Descartes applied algebra to geometry, and was the first to represent the nature of curves by means of equations. Fermat also contributed much to the science; and so did the *Arithmetica Universalis* of Newton. To these names may be added Maclaurin, Moivre, Taylor, Fontaine; and later, Euler, Lagrange, Gauss, Abel, Fourier, Peacock, De Morgan, Sylvester, and Cayley. See articles on ANALYSIS, BINOMIAL, CALCULUS, DETERMINANTS, DIFFERENCE, DIOPHANTUS, EQUATIONS, FRACTIONS, FUNCTION, GEOMETRY, INVOLUTION, NUMBERS (THEORY OF), PERMUTATIONS AND COMBINATIONS, PROBABILITIES, PROBLEMS, SERIES, &c.

Algeciras, or ALGEZIRAS, a town in Spain, in the province of Cadiz, on the Bay of Gibraltar or Algeciras. The town is 5 miles from Gibraltar across the bay, and 9 round by land. Its harbour is bad, but has been improved. The citadel is in a very dilapidated condition. Its climate has made Algeciras a winter resort; its trawlers and whalers make it a fishing-centre. The oranges of Algeciras are famous, as well as its bull-fights. Cork is exported. Population, 20,000. It was the first town in Spain taken by the Moors (711), who held it till in 1344 it was retaken by Alfonso XI., king of Castile, after a twenty months' siege that attracted the interest of all Christendom. Alfonso destroyed the old Moorish town; the modern town was established in 1760 by Charles III. Near Algeciras, on 6th June 1801, the British admiral Saumarez was defeated by the combined French and Spanish fleets, but was completely victorious on the 12th. At Algeciras, from January to April 1906, an international conference met to consider the question of Morocco (q.v.).

Algeria (Fr. *Algérie*), a country on the north coast of Africa, which, since 1830, has been gradually taken possession of by the French, and is now regarded by them as an outlying part of France rather than as a colony. It lies between Morocco on the west side, and Tunis on the east, extending from west to east from about 2° 8' W. to 8° 50' E. long. It extends from the Mediterranean on the north side to an ill-defined limit in the Sahara on the south. The total area is about 343,500 sq. m.

Configuration of Surface.—The coast-line on the north, about 625 miles long, in the form of a very gentle curve, is little indented, steep and rocky, with only a few capes, and comparatively few good ports. From the coast inwards Algeria is marked off into three distinct regions: in the north, the *Tell*—mountainous, cultivated land, with fruitful valleys; in the middle, the region of *Steppes*—mountainous tableland, traversed from west to east by a string of brackish lakes or marshes, called *Shotts*; farther south, the Algerian Sahara, with oases. The Tell, on the north side, is marked by a series of mountain-chains, called by the French the Lesser Atlas or Coast Mountains, comprising the mountains of Blidah, 5381 feet high, and Jurjura, with the peak of Little Khediya, 7572 feet. Farther south, forming the south limit of the Tell, is a parallel chain, the Middle Atlas, extending from west to east. The Tell, forming the mountainous, most fertile, and much the most populous section of Algeria, occupies an area altogether of about 54,000 sq. m., with an average breadth of about 47 miles. The central part of the country—the region of plateaux—extends farther south, from the borders of Morocco to those of Tunis. When the winter rains are

past, the plateau, usually so bare and dreary, grows suddenly fresh with long grass and aromatic herbs, yielding fodder to the cattle that are there reared. The south limit of the middle tableland of Algeria is formed by the chain forming the north boundary of the Sahara, culminating in Sheliab, 7585 feet, the highest point of Algeria. The Algerian Sahara, constituting the third division of Algeria, and covering an area larger than that of both the divisions to the north of it, consists partly of sandy dunes, partly of country covered after rain with herbage; and there are oases round the wells. The Sahara is diversified by masses of rock, often ranged in long parallel chains. The Wady Igharghar is a channel 750 miles long, running from south to north.

The more considerable streams of Algeria rise in the *middle region*, and have therefore to seek their outlet in the Mediterranean, through passes in the middle and coast ranges. They are mostly of a slow current, with narrow mouths often choked with sand. Though swollen in the winter, they shrink in the summer to a thread, or even quite out of sight. Not one of them is navigable, but they are used for purposes of irrigation.

Climate.—The climate of Algeria is distinguished into only three seasons: winter, from November to February; spring, from March to June; summer, from July to October. In winter is the rainy season. The season most congenial for Europeans is spring. During the great heat of summer rain seldom falls. After a hot day, the night is often very cold. The climate of the Sahara is quite tropical, and very oppressive to Europeans. The planting of forests, drainage, and irrigation are effecting great improvements.

Products.—In recent years, despite the ravages of phylloxera, Algeria has developed into a great wine-producing land. By 1912 the area of vineyards had reached 400,000 acres, the production 200,000,000 gallons, the exports £8,650,000—i.e. about two-fifths of the total export trade. Algeria is also coming to the front as a wheat-growing country. The area planted is between 3,000,000 and 4,000,000 acres, and exports are valued at from £1,000,000 to £2,000,000. The area of barley is about the same, and exports have exceeded £1,000,000. Oats claim some 500,000 acres, with an export of about £500,000. Fruit and vegetables are cultivated in large quantities, and exported to the value of £1,500,000. Millions of gallons of olive-oil are shipped to France. Tobacco and cotton are also grown. Artesian wells have converted desert tracts in the Sahara into cultivated land. Palms and fruit-trees flourish in the oases. The tablelands yield inexhaustible supplies of alfa (esparto grass), which is sent to Britain in ever-increasing quantities (over 100,000 tons in 1912). Algeria reckons from 3,000,000 to 4,000,000 agriculturists, of whom 200,000 to 300,000 are Europeans. Pastoral industries are likewise expanding. The 1911 census showed 1,114,000 cattle, 8,528,000 sheep, and 3,862,000 goats. In the three years 1910-12, 3,000,000 sheep and goats (valued at over £4,100,000) were exported—including some 535,000 from Morocco and Tunis; besides wool and hides, each exceeding a million sterling. Forests (covering from 6,000,000 to 7,000,000 acres) are mostly state property. Their most valuable product is cork; exports (1912) 36,775 tons, worth £521,560. Destructive forest fires are frequent. Algeria is rich in minerals. Her shipments rose to nearly £2,000,000 in 1912, phosphates and zinc each accounting for about a quarter and iron nearly a third of the total. Iron, zinc, and lead are worked in all three departments, and copper in Constantine. Mineral springs abound. Petroleum is obtained at Ain Zeff (Oran). Fishing (sardines, anchovies, mackerel, tunny, oysters,

(&c.) is carried on at the chief ports by some 1500 boats.

Trade and Communications.—Goods passing direct between Algerian and French ports may only be carried in French bottoms (*monopole du pavillon*). About half the vessels entered and cleared are French, British ships easily ranking second. Algiers secures half the trade, Oran a quarter, Philippeville a tenth; other ports are Bône, Bougie, Mostaganem, Arzew. Algiers and Oran are important coaling stations. Imports (six-sevenths of which come from France) and exports (three-fourths to France) both more than doubled in the first decade of the 20th century, totalling £26,785,000 and £21,844,000 respectively in 1912. The chief imports are textiles, clothing, sugar, coffee, hides, paper, oil, coal, automobiles, metals, building materials, parcel-post packets. The chief exports are mentioned under *Products*. Over 2000 miles of railway are open. A line from Oran to Tunis was completed in 1887. Other lines from Oran run west and south into Morocco; a railway is pushing inland *via* Boghari from Algiers; and a line from Constantine *via* Biskra to Tougourt is regarded as the first stage of a great 'Trans-Saharian.' Caravan routes lead to Timbuctoo, Nigeria, and the Sudan. Trade with Tunis, Morocco, and Saharan oases has developed greatly in recent years.

Population and Administration.—Algeria is divided into three civil departments—Algiers, Oran, and Constantine (to each of which is attached a military division, not yet under civil administration), and the Southern Territories, organised in 1905, consisting of the districts of Ain Sefra, Ghardaia, Tougourt, and the Saharan Oases. The civil departments are frequently increased by taking in portions of the area heretofore under military government. At the census of 1921 the area and population were as follows:

	Sq. Miles.	Pop.
Algiers Department	65,980	1,788,857
Oran Department	44,620	1,805,031
Constantine Department	78,980	2,162,512
	184,480	5,256,420
Southern Territories	169,020	546,044
	353,500	5,802,464

The above figures comprised nearly 800,000 Europeans, of whom 600,000 were French (over 40 per cent. naturalised, including more than 70,000 Jews), 140,000 Spanish, 40,000 Italians, and some 10,000 Maltese (claiming British citizenship). The native population is divided between Arabs and Berbers. To the former belong the Bedouins living in tents or travelling-huts, and dating mostly from the third Arab invasion in the 11th century. They live chiefly in the Tell, tilling the land and rearing cattle, but are also numerous in the Sahara, where they only rear cattle. The Moors, settled in towns, about 2 millions, are partly of Arabian and partly of the old Mauritanian or Berber stock; they are an impoverished and dwindling population. The Kabyles or old Berbers, about 700,000, inhabit mostly Constantine. There are also negroes employed as day-labourers and servants. Besides the above-mentioned ports, the chief centres of population are Tlemcen, Sidi-bel-Abbès, Mascara, Blida, Tiziouzen, Sétif, Ain Sefra, Laghouat, Biskra; and in the Sahara (q.v.) Tougourt, Guerrara, Ghardaia, Wargla, El Golea, and the oases of Gurara, Tuat, Tidikelt.

Algeria was under military rule from 1834 to 1871, when a civil governor-general, with residence at Algiers, was substituted for the military governor. The governor-general is assisted by a council whose function is purely consultative. Each department sends two deputies and one senator to the French Chambers, which alone have legislative power over

Algeria. The budget is submitted to a Superior Council and to the Financial Delegations, representing French 'colonists' (on the land), urban taxpayers, and Moslem natives. The last-named, who are classed as subjects and not as citizens, have courts and schools of their own. Education is compulsory for Europeans and Jews.

The French troops in Algeria consist of one corps d'armée which, including gendarmerie, numbers upwards of 56,000. A French corps remains in garrison in Algeria for some years; native troops, which may quit Algeria only on extraordinary occasions, consist of four regiments of 'Tirailleurs Algériens' and four of 'Spahis.' There are six regiments of 'Chasseurs d'Afrique' and four of Zouaves, consisting solely of French officers and soldiers. A Foreign Legion, besides, of various nationalities, is mostly officered by Frenchmen. At the head of the Roman Catholic Church in Algeria is the Archbishop of Algiers; there are bishops at Constantine and Oran. Six-sevenths of the inhabitants are Mohammedans.

History.—In the most ancient times we find the Numidians settled in the eastern part of the region, and the Moors (or Mauri) in the west. Under the Romans, the former was included in the province of Africa, while the latter was called Mauritania Caesariensis. It had then populous cities, which were principally Roman colonies. But its conquest by the Vandals, about 440, threw it back into a state of barbarism, from which it only partially recovered after the Mohammedan immigrants had established their dominion. About the year 935, the city of Algiers (q.v.) was built by an Arabian prince, Zeiri, whose successors ruled the land till 1148, after which it was governed by the Almohades till 1269. It was then split up into many small territories. In 1492 the Moors and Jews who had been driven out of Spain settled in Algeria, and began to revenge themselves on their persecutors by piracy. Ferdinand, the Spanish monarch, attacked them on this account, and took the city of Algiers in 1509. One of the Algerine princes, the Emir of Metija, now invited to his assistance the Greek renegade, Horuk Barbarossa, who had made himself famous as a Turkish pirate chief. This laid the foundation of the Turkish dominion; for when Barbarossa arrived in 1516, he treacherously turned his corsair bands against the emir, whom he murdered, and then made himself sultan of Algiers. His subsequent successes alarmed the Spaniards, who marched an army against him from Oran. Barbarossa was defeated in many encounters, and, at last, being taken prisoner, was beheaded in 1518. His brother was then chosen sultan. He put himself under the protection of the Ottoman court, by the help of a Turkish army drove the Spaniards out of the country, and established that system of military despotism and piracy which the English, Dutch, French, Spaniards, and Americans from time to time in vain endeavoured to extirpate, and which lasted till 1830. In that year the town of Algiers capitulated to a French fleet, and the French took possession of the place.

After the revolution of 1830, General Clausel set about subduing the country, and giving it a regular government; but he encountered the most determined opposition in Abd-el-Kader (q.v.), who soon became the rallying-point of the 'holy war,' which the Marabouts had begun to preach. A disgraceful defeat suffered by the French army at Makta caused the recall of the first governor-general, D'Erlon. Clausel was now sent back to Algeria with the title of marshal; but Abd-el-Kader was soon more powerful than ever, and General Bugeaud had to be sent out from France with reinforcements. In February 1837 Marshal Clausel was recalled, and General Damrè-

mont succeeded him. He first attacked the Kabyles of the province of Algiers, and chastised them with severity, and then commenced his great work of taking Constantine, which he ultimately succeeded in storming in May. This victory laid the foundation for the entire subjugation of the province of Constantine.

In 1837 General Valée was appointed governor-general. He, like the others, misunderstood the character of Abd-el-Kader. New treaties were made, which only delayed hostilities. At last, however, deserted by most of his followers, and hemmed in on all sides, the Arab chief was forced to surrender to General Lamoricière at the close of December 1847.

In 1848 the Kabyles broke out into a new insurrection, which, however, was speedily quelled. The French troops penetrated into the far south, almost to the borders of Sahara. In 1853-4, and again in 1856-7, expeditions were organised against the Kabyles. The struggle was sanguinary and barbarous on both sides; and it was only after several defeats sustained by the Kabyles, that, in 1864, peace was restored by the submission of the conquered tribes. Napoleon III. then visited Algeria, and issued a proclamation explaining to the Arabs that Algeria must continue to be united to France, but promising to maintain their nationality, and at the same time giving them assurance that they should always remain in undisturbed possession of their own territories. The Franco-Prussian war in 1870 forced the emperor to withdraw to Europe the greater part of the forces in Africa, and the natives began to entertain hopes of freeing themselves from the yoke of France. Movements were begun in the provinces of Constantine and Oran, which it required all General Durieu's vigilance and activity to hold in check. After this, again, some disorder arose among the colonists themselves, who strongly desired the abolition of the military government—a change which the new republican government at Paris soon gratified them by effecting. To Durieu's place was appointed a civil governor, and under him prefects for each of the three provinces. In 1881, when France entered on a campaign against Tunis, a chief raised the standard of revolt in Algeria, and inflicted considerable losses on the French colonists. Recent years have witnessed the gradual transference of territory from military to civil administration, the penetration of the Sahara (q.v.), and the advancing of Algeria's boundaries.

See *Les Colonies Françaises*, by Petit (1902), and works on Algeria by Gaffarel (1888), Laveleye (1887), Castéran (1900), Bernard (1906), Le Marchand (1913), the 'Guide Joanne,' and in English by Playfair (1874-1902), Wilkin (1900), Hilton-Simpson (1906, 1921), Hilaire Belloc (1906), Nesbitt (1906), Miss Betham Edwards (1912), Devereux (1912), Stott (1914), Casserly (1923).

Alghero, a seaport on the west coast of the island of Sardinia, 15 miles SW. of Sassari. It has a cathedral, a nautical college, and public schools, and is the seat of a bishop. Wine, anchovies, and coral are exported. Pop. 10,000.

Algiers (Fr. *Alger*; Arabic *Al-jazair*, 'the islands'), the capital of Algeria, was built about 935 A.D. by an Arab chief. It rises from the sea-shore up the sides of a precipitous hill in the form of an equilateral triangle. The apex is formed by the Kasbah, the ancient fortress of the deys, which is 500 feet above the sea-level, and commands the whole town. The base is a mile in length. The present city is divided into two parts—the old, or high town; and the new, or low town. With the exception of some mosques, the latter consists of wharfs, warehouses, government houses, squares, and streets, principally built and inhabited by the French; while the former is almost wholly Moorish

both in its edifices and inhabitants. The city is intersected by two large parallel streets, Bab-el-Ouad and Bab-azoun, running north and south for more than half a mile; but the new town of Algiers might deceive the traveller into the belief that he is still in Europe, were it not for the throng of swarthy faces he meets. The streets are regular, spacious, and elegant; some of them as handsome as the Parisian Boulevards, and adorned with arcades. The great glory of the city is the Boulevard de la République, with its magnificent terrace, built in 1860-66 by Sir Morton Peto, at a cost of eight million francs. Here may be found as motley a crowd as anywhere in the world, denizens of all nations. Perhaps greater interest attaches to the old Moorish town, which is connected with the new by a steep, narrow, jagged-looking street called the Kasbah, leading down from the fortress of the deys. The houses are square, substantial, flat-roofed; rise irregularly one over the other; and have no windows to the streets, but only peep-holes, fortified with iron gratings instead of glass, so that the houses have a very prison-like appearance. There are numerous mosques and tombs of saints. The French have at great expense improved the port, which is safe and spacious and has a lighthouse. Work upon a great extension scheme was begun in 1922. Algiers is in the front rank of Mediterranean bunkering stations. It is strongly fortified, and can contain 40 warships and 300 trading-vessels. The original harbour was made in 1525 by connecting with the shore four little islands (hence the name of the city). Near the great quays is the railway station, connecting Algiers with Constantine and Oran. The town has supreme courts of justice, the military and civil headquarters for the province, a chamber and tribunal of commerce, a university and schools, a Catholic cathedral, a French Protestant church, an English church, a synagogue, a library, museum, &c. Algiers accounts for nearly half the oversea trade of Algeria; the produce of the interior is exported, the imports being mainly French goods, with British coal, iron, and cottons. About 600 boats are engaged in fishing. Recently Algiers has become famous as a winter residence for Europeans suffering from chest diseases; the village of Mustafa, near the city, is the resort in summer of the governor and wealthier citizens. The city, which had been wretchedly misgoverned by a long succession of Turkish deys, fell into the hands of the French in 1830. Of the 206,595 inhabitants in 1921, the majority were French (including naturalised Jews); other Europeans were mostly Spaniards and Italians; the rest were for the most part Arabs, Kabyles, and other North Africans. For the department and history of Algiers, see ALGERIA.

Algin. On the surface of certain species of seaweed—notably of those belonging to the genus *Laminaria*—there is sometimes seen a jelly-like material, which is partly formed of a substance called algin, and may be drawn out by the fingers in long tenacious strings. The cell-walls of our common brown seaweeds (*Fucus* and *Laminaria*) are, in fact, very mucilaginous, and all contain algin, which has somewhat remarkable properties. This substance was discovered in 1881 by Mr E. C. C. Stanford of Glasgow. If the leaf-like thalli of a *Laminaria* are immersed in water containing a little carbonate of soda, the whole cellular fabric of the plant becomes broken up in the course of twenty-four hours, forming a thick gelatinous mass containing about 2 per cent. of algin. This mass, after being cautiously heated, is filtered through coarse linen, and the cellulose which is left behind amounts, when dry, to from 10 to 15 per cent. of the air-dried plant. The solution which passes

through the filter contains, in addition to the algin in the form of alginate of soda, some mucilage and dextrine. When sulphuric or hydrochloric acid is added, the algin, or, more correctly speaking, the alginic acid, separates in flocks, and is easily washed and pressed in a filter-press. In this condition it forms a compact cake not unlike new cheese. Chemically, it is a nitrogenous organic acid, and is the insoluble form of algin. When required for use in a soluble state, it is redissolved to saturation in solution of carbonate of soda, when alginate of soda is again formed.

The properties of algin in the soluble form are those of a very viscous gum, drying up to a transparent elastic film. As a size or dressing for textile fabrics, algin goes farther than starch, and is easily rendered insoluble in water. It is used for jujubes, and makes an excellent thickening for soups and jellies. The insoluble form of algin, in the dry state, resembles horn, and can be turned and polished. It is also employed as jacketing for boilers.

Algoa Bay, a broad inlet at the south-eastern extremity of the Cape Province, with a good anchorage; Port Elizabeth lies in the SW. angle.

Algol, a variable star in Perseus, which once in 2 days 20 hours 49 minutes falls from above the second magnitude to below the third, through the interposition between it and us of a dark satellite or companion star. It is believed by some that there is a third invisible component of the Algol system.

Algonquins, the most prominent of the three aboriginal races (the other two being the Hurons and Iroquois) that occupied the great basin of the St Lawrence at the beginning of the 17th century. In what is now the United States, the Algonquin tribes occupied all the coast-region from the NE. limit to the James River in Virginia, and were found westward nearly as far as the Rocky Mountains. The Six Nations, and other tribes of Iroquois, were surrounded by Algonquins. The Abenakis, the Micmacs, the Delawares, the Mohegans, the Shawnees, the Pequots, the Ojibways, the Crees, and perhaps also the Blackfeet and Cheyennes, were among the numerous tribes of Algonquin stock. In a much narrower sense, the name is now applied to the relics of an Indian people in the province of Quebec, Canada. See Leland's *Algonquin Legends of New England* (1884).

Alguacil, or ALGUAZIL (Arabic *al-wazir*, 'the vizier'), is the general name in Spain of the officers intrusted with the execution of justice.

Alhag'i is an Arabic name for a genus of low shrubs from which Manna (q.v.) exudes.

Alham'a (Arabic *Al Hammam*, 'the bath'), a town of Andalusia, Spain, in the province and 24 miles SW. of Granada. Its situation is extremely picturesque, on the edge of a projecting rock; but it is a decayed town, although its warm sulphur baths are still frequented by visitors. It was a famous fortress of the Moors; and there are still remains of Roman and Moorish buildings. The town was much injured by a severe earthquake in the end of 1885. Pop. 8000. —ALHAMA DE ARAGON, 8 miles SW. of Calatayud, has famous mineral springs. Pop. 1300. —ALHAMA, 13 miles SW. of Murcia, is also celebrated for its warm mineral waters. Pop. 8000.

Alham'bra, a fortified suburb of Granada, which forms a sort of acropolis to the city, and in which stand the exquisite remains of the palace of the ancient Moorish kings of Granada. The name is a corruption of the Arabic *Kal'at al hamra*, 'the red castle.' It is surrounded by a strong wall, more than a mile in circuit, and studded with towers. The towers on the north wall, which is defended by nature, were used as residences connected with the palace. One of them contains the famous *Hall of the Ambassadors*. The remains of the Moorish palace are called by the Spaniards the Casa Real. It was begun by Ibn-l-ahmar (1248), and completed by his grandson, Mohammed III., about 1314. The principal decorator was Yusuf I., who regilt and repainted the palace; and even yet, in the dry climate of Spain, traces of his work have been preserved. The portions still standing are ranged round two oblong courts, one called the *Court of the Fish-pond*, the other the *Court of the Lions*. They consist of porticos, pillared halls, cool chambers, small gardens, fountains, mosaic pavements, &c. The

Alhambra.

lightness and elegance of the columns and arches, and the richness of the ornamentation, are unsurpassed. The stone lacework scattered over all the building appears to those ignorant of Arabic mere quaint and beautiful scrolls, but is really a complex arrangement of Arabic poetry and verses from the Koran. The colouring, which often is marvellously preserved, employs only the three primary colours, among which the metallic blue greatly predominates, although the atmosphere has transformed much of it to green. Entrance is by a horseshoe arch, called by the Moors the 'gate of the law,' where the king sat to administer justice. Here, as almost everywhere else, the Moorish diaper-work is much broken, in this instance to make a niche for a wooden image of the Virgin. In the most beautiful room in the palace, the *Hall of the Abencerrages* (q.v.), to the beauty of colour and of ornamentation is added an arcade resting on light and graceful marble arches that run round the place. The most characteristic parts of the Casa Real have been reproduced in the 'Alhambra Court' of the Crystal Palace at Sydenham. A great part of the ancient palace was removed to make way for the palace begun by Charles V., but never completed. Since then it has suffered from the neglect and greed of successive governors; from the French, who blew up eight of its towers and tried to destroy the whole; from earthquake; and from fire (Sept. 16, 1890). There have been partial restorations (1845, 1862, &c.). See works by

Washington Irving (1832; Pennell's ed., 1896), Owen Jones (1848), Murphy (1856), Calvert (1904); also ARABESQUE and ARABIAN ARCHITECTURE.

Ali, the first convert to Mohammedanism, and fourth of the khalifs, was the son of Abu Taleb, the Prophet's uncle. He was the bravest and most faithful follower of the Prophet, whose daughter Fatima he married. Being made khalif in 656 A.D., in the place of the murdered Othman, he was ultimately, after a sore struggle, victorious over those who opposed his authority, and took prisoner Ayesha, the young widow of Mohammed, who was the soul of the rebellion. Ali was assassinated in the year 660, and buried near Kufa. The question of his right to succeed to the khalifate permanently divided the Mohammedan world; the Shiites (q.v.) still reverencing him as next to Mohammed, while the Sunnites (q.v.) abhor his memory. He was famed for wisdom; but the maxims (ed. Fleischer, Leip. 1837) and the lyrics (Boulak, 1840) attributed to him are not authentic.

Aliaska, a peninsula of Alaska (q.v.).

Ali Bey, of Egypt, was a Caucasian slave, born in 1728, who rose to be chief of the Mamelukes in 1763, gained followers, slaughtered the other beys in 1766, and was proclaimed sultan in 1768. He made himself independent of the Porte, and had conquered Syria and part of Arabia, when one of his sons-in-law deserted him, and raised an army against him in Egypt. In April 1773 he was defeated in battle, and a few days after died of his wounds or of poison.

Ali Pasha (surnamed *Arslan*, 'the Lion') was born in 1741, at Tepeleni, a village of Albania. His mother, a vindictive and merciless woman, inspired him with the remorseless sentiments that animated herself. His youth was passed in extreme peril and hardship, for the neighbouring pashas had robbed his father of nearly all his possessions, in the effort to recover which, young Ali was repeatedly defeated. It is said that the change in his fortunes arose from his accidental discovery of a chest of gold, with which he raised an army of 2000 men, gained his first victory, and entered Tepeleni in triumph. On the very day of his return, he murdered his brother, and then, on the charge of having poisoned him, imprisoned his mother in the harem, where she soon after died. He next reconciled himself to the Porte by helping to subdue the rebellious Vizier of Scutari. Appointed lieutenant to the Derwend Pasha, an officer charged with the suppression of brigandage, he rendered the high-roads more insecure than ever, sharing in the plunder of the *klephts* (robbers). The result was his deposition by the Porte; but he speedily bought back its favour, for he was a master-hand at bribery. Shortly after this, he did such good service to the Turks in their Austro-Russian war of 1787, that he was named pasha of Trikala in Thessaly; at the same time he seized Janina, of which he got himself appointed pasha by the instrumentality of terror, a forged firman, and bribery. In 1797 he entered into alliance with Napoleon, who sent him engineers; but next year, after the battle of Aboukir Bay, he wrested the seaport Prevesa from the French. After a three years' war, he subdued the Suliots, for which the Porte promoted him to be governor of Rumili. About this time, he revenged on the townsfolk of Gardiki an outrage done to his mother forty years before, by the murder of 739 male descendants of the original offenders, who themselves were all dead. Within his dominions, Ali maintained strict order and justice. Security and peace reigned, high-roads were constructed, and industry flourished, so that the European

travellers, with whom he willingly held intercourse, considered him an active and intelligent governor. From 1807, when he once more formed an alliance with Napoleon, Ali's dependence on the Porte was merely nominal. Having failed, however, to obtain at the peace of Tilsit, Parga, on the coast of Albania, and the Ionian Islands, he now entered into an alliance with the British. For years he was despot of Albania, Thessaly, Epirus, and part of Macedonia. Deeming his power securely established, he caused the commanders of the Greek *Armatoles* (or militia), who had hitherto aided him, to be assassinated one by one, while at the same time he put to death the assassins. The Porte resolved at length to end the power of this daring rebel, and in 1820 Sultan Mahmoud sentenced him to be deposed. Ali resisted for a time several pashas that were sent against him, but at last surrendered, on the security of an oath that his life and property would be granted him. Nevertheless he was put to death, February 5, 1822. See Davenport, *Life of Ali Pasha* (1861), and Boppe, *L'Albanie et Napoléon* (1914).

Alias is a name given in England to a second writ issued when the first has failed, but is more commonly used in both England and Scotland as part of an indictment describing a prisoner who goes by more names than one. The indictment used to be in Latin, and *alias dictus* is (late) Latin for 'otherwise called.' Under the Indictments Act, 1915, Rule 7, all that is necessary is that the description of an accused person shall be such as is reasonably sufficient to identify him. In Scotland the accused may be indicted by the name given by him when examined on declaration; and the prosecutor need not set forth any 'alias' by which the accused has passed. Aliases are generally used at trial for the purpose of proving previous convictions under the other names.

Alibi (Lat., 'elsewhere') is a defence resorted to in criminal prosecutions, when the accused, in order to prove that he could not have committed the crime, tenders evidence to the effect that he was in a different place at the time the offence was committed. In Scotland, though not in England, the prisoner, if he is to be tried by jury, must give notice to the crown of a special defence of *alibi*, stating where he was at the time of the crime. If he is to be tried summarily, notice of a plea of *alibi* must be given to the prosecutor prior to the examination of the first witness for the prosecution.

Alicante, chief town of a like-named province in Spain, on a bay of the Mediterranean, 46 miles N.E. of Murcia by rail. The castle of St Barbara commands the town and bay. The town with its background of mountains looks picturesque from the sea. The church of San Nicolas de Bari is dedicated to Alicante's tutelary saint. It is among the leading seaports of Spain, and its harbour is spacious and secure. The chief exports are esparto grass, oranges, wine, almonds, and liquorice-root; tobacco, petroleum, dried fish, timber, coal, and spirit for strengthening wine are imported. A great tobacco-factory employs many hands; but, though helped by the railway to Madrid (282 miles), the local trade is not great. The climate is well suited for invalids. In 1331 the town was besieged by the Moors, and again by the French under Asfeld in 1709. In 1873 it was unsuccessfully bombarded by two warships manned by Cartagena insurgents. Pop. 42,000.—The province (2200 sq. m.; pop. 500,000) was formed in 1834 of parts of the old kingdoms of Valencia and Murcia. The surface is diversified with mountain-ranges in the north and west, but is more level to the south, with fertile valleys. The chief products are esparto grass, rice, sugar-cane, and fruits. The wine

has a high reputation. Bees and silkworms are reared. There are lead and copper mines. The coast-dwellers are engaged chiefly in tunny and anchovy fishing and the carrying trade.

Alien (Lat. *alienus*) is a general term denoting a person who is not a citizen of the state. The rules determining what persons are, or are not, citizens of a particular state depend on the law of that state, and vary in different states. The law as to British nationality and the status of aliens was consolidated and amended in the British Nationality and Status of Aliens Act, 1914 (4 and 5 Geo. V. chap. 17), which repeals the earlier statutes, and by two important Acts of 1918 and 1922. An 'alien' is defined in the act as 'a person who is not a British subject'—i.e. who is neither a natural-born British subject nor a naturalised British subject. British nationality is acquired at birth, irrespective of parentage, by persons born within the king's dominions and allegiance, or on board a British ship. Further, any person born out of the king's dominions whose father was a British subject at the time of that person's birth is a natural-born British subject. A naturalised British subject is one who has acquired British nationality by Naturalisation (q.v.). A woman acquires by marriage the nationality of her husband. Thus the wife of a British subject is a British subject, and the wife of an alien is an alien. But where a man ceases during the continuance of his marriage to be a British subject, his wife may make a declaration that she desires to retain British nationality, and thereupon she remains a British subject. A woman who, having been a British subject, has by her marriage become an alien does not by reason only of the death of her husband, or the dissolution of her marriage, cease to be an alien.

British nationality may be lost by a person, when in a foreign state and not under any disability, becoming naturalised, voluntarily and formally, in that state. But a British subject may not become naturalised during a war in an enemy state; such naturalisation is an act of treason (Reg. v. Lynch, 1903, 1 K.B. 444). A person who, under English law, is a British subject may, under the law of a foreign state, be a subject also of that state. Thus a child born in England of a French father is both a British subject and a French citizen. In the case of such double nationality, the person is entitled, if of full age and not under disability, to make a 'declaration of alienage,' and thereupon ceases to be a British subject. But a natural-born British subject of double nationality has been held not to be entitled to make a declaration of alienage in time of war, so as to become solely a subject of the enemy state; nor can he, by executing a declaration of alienage, claim discharge from the army. When a person ceases to be a British subject, by declaration of alienage or otherwise, his minor children also become aliens; but any child who has in this way become an alien may, within one year after attaining his majority, make a declaration that he wishes to resume British nationality, and thereupon he again becomes a British subject.

The allegiance due from an alien resident is known as 'local' allegiance; see ALLEGIANCE.

By the common law of England, an alien, though the subject of a friendly state, was incapable of inheriting, or acquiring by purchase, lands within the realm. This rule was abrogated by the Naturalisation Act of 1870, and now real and personal property of every description may be acquired, held, and disposed of by an alien; and a title to such property may be derived through, from, or in succession to an alien, in the same manner in all respects as through, from, or in

succession to a natural-born British subject. It is also expressly enacted that an alien shall be triable in the same manner as if he were a natural-born British subject. The main distinctions between the legal position of aliens and that of British subjects are that an alien is excluded from holding any public office, and from exercising any franchise, parliamentary or municipal, and that he cannot own a British ship or a share in one. Under the Aliens Restrictions Act, 1914, and relative orders, many restrictions were imposed even on alien friends during the war. An alien has no enforceable right to enter British territory. The Aliens Act, 1905, prohibits the landing in the United Kingdom of undesirable alien steerage passengers from 'immigrant' ships. Under the act an alien is deemed 'undesirable' if he is without the means of decently supporting himself and his dependants, if he is diseased or infirm and likely to become a charge on the rates or otherwise a detriment to the public, or if he has been sentenced for certain crimes. There is a saving clause for those fleeing from religious or political persecution. The act also empowers the Secretary of State to make rules for the expulsion from the United Kingdom of aliens convicted of offences of a certain gravity by any court and recommended by that court for expulsion, or of aliens who have become within a limited time after their arrival in the United Kingdom a charge on the rates, or who have been sentenced in a foreign country for crime. The Aliens Restriction Act, 1919, continues certain powers conferred upon the executive government during the war with respect to aliens, and imposes some restrictions unknown before the war.

An alien whose sovereign or state is at war with Great Britain is an alien enemy; see ENEMY.

Restrictions on alien immigration have been imposed in Canada, in Australia, and in many other British colonies. Thus in Canada, under the Alien Labour Act, 1906, it is unlawful to prepay the transportation or in any way assist the immigration of any alien under a previous contract to perform labour. The act does not apply to persons employed as domestic servants. Similarly in Australia persons who are under contract to perform manual labour may be excluded. In several colonies there is special legislation regulating the admission of aliens of coloured races.

In many states restrictions are still imposed on the right of aliens to hold land. In the United States there is considerable diversity in the legislation of the several states on this matter.

In the United States, as in England, children born out of the country are not aliens if their fathers are citizens. The alien, though not admitted to the same political and municipal rights as the citizen, is protected in person and property against wrong.

Aligarh, a fort in the district of the same name in the United Provinces of India, between Agra and Delhi. It was stormed by Lord Lake in 1803, being then the principal depot of the French general acting for Sindhia. Ten days after the outbreak at Meerut in 1857, the native troops in garrison mutinied; and the loss of the place almost cut off the communications between the south-east and the north-west. Its great and successful Muslim university (1920) superseded the Muhammadan Anglo-Oriental college founded by Sir Saiyid Ahmad Khan. Both Shiah and Sunnis are found amongst the students.

Alignment. See CALLERNISH, CARNAC, STANDING-STONES.

Aliment, in the law of France and in that of Scotland, has retained the meaning which it pos-

sessed in the Roman law (*Dig.* 34, 1, 6), and signifies the food, dwelling, clothing, and other things necessary to the support of life, or such money as may be judicially demanded in lieu of them. In Scots law a father is liable to aliment children so long as the latter are unable to support themselves, and in the higher ranks still longer, if the child be destitute, especially in the case of daughters. As to illegitimate children, see **BASTARD**. The obligation does not extend to a son's wife, nor to brothers or sisters or other collateral relations. The duty devolves on the father's representatives, and also on the mother, if the father be indigent or dead. The grandfather must aliment his destitute grandchildren. The obligation in every case is satisfied by a bare subsistence, although this may vary slightly according to the social position of the parties. Children are liable to aliment indigent parents. A husband is liable to aliment his wife, but, unless he has acquired property by his marriage, he is not bound to support his wife's parents. In the case of both wife and child, it is enough to offer them a home. The liability to aliment a wife is not terminated by a judicial separation, but only by divorce. Persons unable to support themselves, through age, or bodily or mental disease, are entitled to relief under the poor-law, but this aliment may be recovered from the pauper's relatives. Money may be settled in trust for the aliment of persons, so as to exclude the diligence of creditors.

Alimentary Canal is the name given to the principal part of the digestive apparatus. It extends from the mouth to the anus, having in man an average length of about thirty feet. Passing through the head and chest, it includes the *teeth*, the organs of mastication; the *salivary glands*, the organs of insalivation; the *tongue*, *pharynx*, *œsophagus* or gullet, the organs of deglutition. In the abdomen and pelvis there are the *stomach*, and *small and large intestine*. Intimately concerned in the process of digestion, there are numerous small glands in the lining membrane of the canal besides such large ones as the *salivary glands*, the *liver* and *pancreas*, which pour their secretions into the interior of the canal by ducts opening upon its inner surface. See articles on the various portions, and (especially) **DIGESTION**.

Alimony signifies, in English law, the allowance which a married woman is entitled to receive out of her husband's estate, *pendente lite*, or after decree of judicial separation. On any decree for dissolution or nullity of marriage the court has power to make an order that the husband shall provide a gross sum or an annual sum for the support of the divorced wife (*Matrimonial Causes Act*, 1907, sect. 1). In the case of divorce, the court can deal with the settlements. Alimony is sometimes called maintenance. In the United States also it is fixed by the court, and generally proportioned to the standing and mode of life of the parties.

Alisma'cæ, a small order of monocotyledonous plants, interesting on account of its remarkably close affinities to the dicotyledons, through *Ranunculacæ*. It contains about ten widely distributed genera of herbaceous plants, usually growing in water or even floating. The fleshy rhizome of the water-plantain (*Alisma plantago*), common in Britain, is sometimes used as food in Eastern Russia. See also **ARROWHEAD** (*Sagittaria*).

Alison, ARCHIBALD, born at Edinburgh in 1757, studied at Glasgow University and Balliol College, Oxford, and in 1784 received Anglican orders. He had held several preferments, including a prebend of Salisbury, and the perpetual curacy of Kenley, in Shropshire, when in 1800 he removed

to Edinburgh, and served there as an Episcopal minister till 1831. He died 17th May 1839. Alison was best known by his *Essays on the Nature and Principles of Taste* (1790), whose second edition, in 1811, gave occasion to an admiring article by Jeffrey, in the *Edinburgh Review*. They advocate the 'association' theory of the sublime and beautiful, and are written much in the style of Blair, as are also 2 vols. of Alison's *Sermons* (1814-15).—His son, WILLIAM PULTENEY ALISON, born in 1790, was professor of the institutes of medicine in the university of Edinburgh from 1822 to 1856. In 1840 he published a pamphlet to show how the inadequate provision for the poor in Scotland led to desolating epidemics; and he was also author of a dozen other medical and miscellaneous works. He died September 1859.—A younger son was SIR ARCHIBALD ALISON, the historian. Born at Kenley, Shropshire, in 1792, he entered Edinburgh University in 1805, and in 1814 was called to the Scottish bar. Three years after, he was making £600 a year, and this large income allowed him to form a fine library, and make four continental tours, till, in 1822, he was appointed advocate-depute, an office he held till 1830. He now began to appear as a writer on law, politics, and literature. His *Principles of the Criminal Law of Scotland* (2 vols. 1832-33) is still a standard authority. In 1834 Sir Robert Peel appointed him sheriff of Lanarkshire, and thenceforth he resided at Possil House, Glasgow. In 1845 he was elected Lord Rector of Marischal College, Aberdeen; of Glasgow University in 1851; and a baronetcy was conferred on him in 1852. He died 23d May 1867. His *History of Europe during the French Revolution* (10 vols. 1833-42) narrates the events from 1789 to 1815, and was continued under the title of *The History of Europe from the Fall of Napoleon to the Accession of Louis Napoleon* (9 vols. 1852-59). He also published *Lives of Marlborough, Castlereagh, and Sir Charles Stewart*, *The Principles of Population, Free Trade and Protection, England in 1815 and 1845*, &c., besides contributing for many years to *Blackwood's Magazine* a series of tedious articles on Tory politics. His *magnum opus*, *The History of Europe*, designed, as was said, 'to prove that Providence was on the side of the Tories,' is a work of immense industry and respectable accuracy, but shows little insight, and in style is excessively wordy; yet it passed through numerous editions and was translated into several languages. See his *Autobiography* (2 vols. 1883).—His son, SIR ARCHIBALD ALISON, G.C.B., born at Edinburgh in 1826, was educated at Glasgow and Edinburgh universities, and entered the army in 1846. He served in the Crimean war; the Indian Mutiny, losing his left arm at the relief of Lucknow; the Ashanti expedition; and the Egyptian campaign, leading the Highland brigade at the battle of Tel-el-Kebir. In 1885-89 he held the command at Aldershot, and he wrote *On Army Organisation*. He died 5th February 1907.

Aliwal, a Punjab village on the left bank of the Sutlej, 9 miles W. of Ludiana. It was the scene of a fierce conflict between the British and Sikh forces, 28th January 1846. The Sikhs had crossed the river, when they were attacked by Sir Harry Smith, defeated, and driven back with great slaughter. The victory of Aliwal is described as being technically 'without a fault.'

Aliwal North, capital of a like-named district in the Cape Province, on the Orange River, 160 miles NNW. of East London, with which it has rail connection. Near are the Aliwal sulphur springs. Pop. 4500, of whom 2000 were whites.—**ALIWAL SOUTH**, now called **MOSSSEL BAY**, in the Cape Province, 30 miles SW. of George. Mossel Bay is

a summer-resort and centre of a large forwarding trade. The port is protected from westerly gales by Cape St Blaize. It is connected with Capetown by rail (312 miles) *via* Worcester. Pop. 4500.

Alizarin, the colouring matter used in the dyeing of Turkey red, exists in the madder root as a glucoside, which, when boiled with acids or alkalis, gives glucose and alizarin. But in 1868 Graebe and Liebermann discovered a method of manufacturing it from the coal-tar product Anthracene (q.v.), now one of the most important branches of the coal-tar colouring industry. This manufacture, begun on a commercial scale by Perkin in 1869, speedily put an end to the growing and importing of madder root. One ton of alizarin was reckoned equal in colouring power to nine tons of madder; and the cost of the artificial dye was less than a third of the natural dye, though inferior in permanence. Alizarin crystallises in dark-red prisms, melting at 296° C., and moderately soluble in alcohol. With certain metallic oxides it forms a coloured insoluble salt known as a *lake*, and its important dyeing applications are due to this property. Alizarin is one of those dyes which need the presence of one of these oxides before a fast dye is produced in the texture to be treated. See DYEING.

Aljubarrota, a village on a height in Estremadura, Portugal, about 60 miles N.E. of Lisbon, where John of Portugal, with the assistance of English allies, gloriously defeated the Castilians on 14th August 1385, thus securing Portuguese independence.

Alkahest, or **ALCAHEST**, the universal solvent of the alchemists. See **ALCHEMY**.

Alkalies. The word *alkali* is of Arabic origin, *kali* being the name of the plant from the ashes of which an alkaline substance was first procured. The name now denotes a class of substances having similar properties. The common soluble Bases (q.v.) or alkalis are three in number—potash, soda, and ammonia. The first two are hydroxides of the metals; the last a solution of ammonia gas in water, and was formerly called the *volatile alkali* owing to its tendency to reform ammonia gas and water. Potassium and sodium are often referred to as the *alkaline metals*, and have very soluble hydroxides. Potash, being largely present in the ashes of plants, is called the *vegetable alkali*; and soda, predominating in the mineral kingdom, is designated the *mineral alkali*. The *alkaline earths*, as they are called—lime, magnesia, baryta, and strontia—are distinguished from the former by their hydroxides being only slightly soluble in water. The distinguishing property of alkalis is that of turning litmus blue and vegetable yellows reddish brown. Blues reddened by an acid are restored by an alkali. The alkalies have great affinity for acids, and combine with them, forming salts, in which the peculiar qualities of both alkali and acid are generally destroyed; hence they are said to neutralise one another. In a pure state alkalis are extremely caustic, and act as corrosive poisons. Combined with carbonic acid, especially as bicarbonates, they are used to correct acidity in the stomach; but the injudicious and continued use of them is attended with great evil. The alkalies and some of their salts (e.g. citrates, tartrates) are also used to increase the secretion of urine, and (ammonia excepted) to diminish its acidity. Ammonia in small doses is a powerful stimulant. An account of the several alkalis will be found under the heads of **POTASSIUM**, **SODA**, **LITHIUM**, and **AMMONIA**; and of the alkaline earths, under **LIME**, **MAGNESIUM**, **BARYTA**, and **STRONTIUM**.

Alkalimetry. Commercial potash and soda always contain greater or less quantities of foreign substances, such as sulphate of potash, common salt,

silicates, oxide of iron, water, &c., which diminish the percentage of real alkali in a given weight. It is important, then, for the manufacturer to have some simple and ready means of determining the proportion of pure carbonate of potash or soda contained in any sample, that he may be able to judge of its value. This is done by means of *volumetric analysis*. This supplies a quick and ready method for at once determining the amount of acid or alkali in any liquid or solid. A known weight of the substance is dissolved in water and made up to a known volume. In the case of liquids, a definite volume is diluted with water and made up to a standard volume, either 250, 500, or 1000 cubic centimetres. The solutions used in volumetric analysis are always made up to a standard strength. A standard solution is said to be *normal* when the molecular weight of the substance in grams is dissolved in water and made up to a volume of 1000 c.c. (a litre). If this is too concentrated, then the solution is made semi-normal (half the concentration of normal), or deci-normal (one-tenth the concentration of normal). Now the molecular weight of potassium hydroxide, KOH (caustic potash), is 56; therefore a normal solution is made by dissolving 56 grams in water and diluting it till it fills a litre flask. The flask is pear-shaped, with a long, narrow neck, on which there is a mark engraved. When filled up to this mark it contains exactly 1000 c.c. of liquid. Flasks of this description can be got in 100, 250, 500, and 1000 c.c. capacity, these being the usual sizes used in volumetric work.

A normal solution of nitric acid (HNO₃) contains 63 grams of pure acid per litre. But a normal solution of sodium carbonate (Na₂CO₃, molecular weight 106) only contains 53 grams per litre, because a molecule of monobasic hydrochloric acid can only neutralise half a molecule of sodium carbonate.

Similarly, a normal solution of sulphuric acid (molecular weight 98) has only 49 grams per litre. Before a standard or volumetric solution of hydrochloric or sulphuric acid can be made, one has to take some alkali which can be obtained very pure, and use it as the standardising agent. For this purpose sodium carbonate is employed, since it can be got in a pure state. Fifty-three grams are dissolved and made up to 1 litre with distilled water in the special graduated flask. The sulphuric acid normal solution is now made in the following way: By means of a hydrometer and the use of specific gravity tables a solution is made containing roughly a little more than 49 grams in the litre. It is now wanted to ascertain how much of the normal alkaline solution is required exactly to neutralise 10 c.c. of this sulphuric acid. The exact point when the acid is all neutralised, and before excess of alkali is added, is shown by an *indicator*. Litmus solution is frequently used, being coloured blue in presence of alkali, and red in presence of acid. The neutral point is shown when neither red nor blue colour is seen, but a change from red to blue or *vice versa* is just taking place, the liquid being vigorously stirred. Other indicators are phenolphthalein (red in acid, almost colourless in alkali), methyl-orange, &c.

In order to perform the *titration* accurately, use is made of the *pipette* and the *burette*. The pipette is a glass tube, drawn out to a fine point at the lower end, having a bulb in the middle and a narrow tube at the upper end. When it is filled up to a mark on the neck the capacity is exactly 10, 20, or 25 c.c. according to the pipette used. For most purposes the 10 c.c. pipette is generally employed. The liquid is sucked up above the mark, and the upper end is closed by the forefinger. On relieving the pressure of the finger, the level of the liquid

falls; pressure again being applied when it is at the mark. The solution is then allowed to run into a beaker. The burette is a long, narrow glass tube which is held in a stand in a vertical position. It is graduated in cubic centimetres, and has a capacity of 50 c.c. By means of a stopcock at its lower extremity any amount of liquid can be run off, the number of cubic centimetres being read off the graduated scale. To perform a titration the burette is filled with the normal solution of alkali, 10 c.c. of the acid being pipetted into the beaker. An indicator is added, and the contents of the burette are slowly run into the beaker. When the indicator shows the neutral point the stopcock is shut, and the quantity which has been run out is read off. By this means one finds out whether 10 c.c. of the acid neutralises exactly 10 c.c. of the normal alkali solution. If not, the acid must be diluted sufficiently until 10 c.c. is exactly equivalent to 10 c.c. of normal alkali. The solution now obtained is a normal solution of sulphuric acid, and can be used in a similar way for determining the strength of any alkali, or for making up standard solutions of alkalies. In every chemical laboratory there are always kept several stock solutions of standard strength, so that it takes only a few minutes to carry out a titration. Owing to the speed and accuracy of working volumetric analysis is of great importance, and is employed when possible rather than other kinds of quantitative chemical analysis. There are many applications of volumetric analysis in general use, standard solutions of the following being largely used: (1) potassium permanganate and potassium bichromate for the estimation of iron (in the ferrous state); (2) sodium thio-sulphate for estimating the amount of chlorine in bleaching-powder, &c.; (3) sodium chloride for the estimation of silver; (4) silver nitrate for the estimation of chloride. Many other estimations can be made, too numerous to mention here.

Alkaloids, a term used to designate the nitrogenous basic principles existing naturally in plants. These are often called vegetable alkaloids to distinguish them from alkaloids of animal origin. It must not, however, be assumed that when a plant contains an alkaloid it is of necessity the active principle, which may rather be a resin, glucoside, volatile oil, or vegetable acid. Most of the alkaloids consist of carbon, hydrogen, nitrogen, and oxygen, and are solid bodies at the ordinary temperature. A few, however, only contain carbon, hydrogen, and nitrogen, and these are for the most part liquids which can be distilled without decomposition. The more important of this class are coniine and nicotine. The alkaloids have generally an energetic action on the animal system, and hence are every day employed in small doses as medicine; whilst in comparatively large doses they are powerful poisons. Many of them have an alkaline reaction on vegetable colours; but in the greater number this property is possessed only in a very faint degree, and it is by analogies, based on other properties, that they are all classed under one title. There is only one property common to all alkaloids—namely, that they combine directly with acids to form more or less stable salts, capable of undergoing double decomposition; as, for example, sulphate of quinine, muriate of morphine, &c. Most of the alkaloids have an acrid, bitter taste, and are sparingly soluble in water, more freely so in alcohol, chloroform, and ether. As many alkaloids occur together in the same plant, and other substances are also present, such as glucosides, tannic acid, malic acid, &c., the extraction and purification is a difficult matter. In general, the vegetable extract is treated with dilute acid, with which the alkaloid combines to form a soluble salt. The residual vegetable matter is then filtered off, and to the solution a strong

alkali is added which usually precipitates the alkaloid. The alkaloid is then purified by crystallisation from a suitable solvent such as alcohol, ether, or chloroform. Several of the alkaloids have been prepared artificially, such as piperine and coniine; although the more important alkaloids, quinine and morphine, as yet have defied artificial production. Generally speaking, the alkaloids are tertiary, aromatic bases; but the constitutions of many of them have not yet been determined. It is known, however, that many alkaloids are derivatives of pyridine, quinoline, or isoquinoline. The following list contains the names of the chief alkaloids, with the plants from which they are obtained:

Alkaloids.	Source.	Alkaloids	Source
Aconitine.....	Aconite.	Hyoscyne ..	Henbane.
Angosturine.....	Cusparia.	Hyoscyamine ..	Hops.
Atropine.....	Belladonna.	Lupuline ..	Morphine.....
Belladonnine.....	Bebeeru Tree.	Codaine.....	Opium.
Beberine.....	Barberry.	Narcotine.....	Tobacco.
Berberine.....	Calumba.	Nicotine.....	Jaborandi.
Cocaine.....	Coca Leaf.	Piperine.....	Black Pepper.
Coniine.....	Henlock.	Quinine.....	Cinchona.
Curare.....	Arrow Poison.	Cinchonine ..	Cinchonidine ..
Cytisine.....	Laburnum.	Sinapine.....	Mustard.
Laburnine.....	Stramonium.	Strychnine.....	Nux Vomica.
Daturine.....	Ergot.	Brucine.....	Cevadilla.
Ergotamine.....	Eserine or Physostigmine.....	Veratrine.....	
	Calabar Bean.		

Animal alkaloids is a term, now disused, which used to be applied to bodies similar to alkaloids obtained from animals—e.g. urea, creatin, &c. Many alkaloids can be detected by chemical methods even when present in very small quantity. This has an important bearing in medico-legal cases. In the well-known murder case against Dr Crippen in the summer of 1910, it was proved that he had used hyoscyne hydrobromide, an alkaloid, for poisoning his victim. Although the body had lain in a cellar for a few months, by means of a colour-test which reacts for only a few definite alkaloids the presence of this salt was proved beyond a doubt. It is said that one ten-thousandth of a milligram of hyoscyne hydrobromide can be detected.

Alkan, CHARLES HENRI VALENTIN MORHANGE, professional name of a pianist, music teacher, and composer who was born in Paris in 1833, and died there, 29th March 1888. His compositions for the piano include marches, préludes, caprices, and études of great technical difficulty.

Alkanet (*Anchusa tinctoria*, to which the name Alkanet or Alkanna—Arabic *Al-cherneh*—more strictly belongs) is a native of the Levant and of the south of Europe, extending as far north as Hungary. The root is sold under the name of alkanet or alkanna root, and is imported from the Levant. It appears in commerce in brittle pieces of the thickness of a quill or of the finger, the rind blackish externally, but internally dark red. It is sometimes adulterated with dyed roots of common alkanet (*Anchusa officinalis*). The root of *Lawsonia inermis*, a Lythraceous plant, was formerly often imported under the same name. Alkanet-root contains a resinous red colouring-matter, called *Alkanna Red* (*Alkannin* or *Anchusin*). The colour which it yields is very beautiful, but not very durable. It is readily soluble in oils and alcohol, and is therefore in very general use amongst perfumers for colouring oils, soaps, pomades, lip-salves, &c., and in the composition of stains and varnishes. The name of alkanet is also extended to the whole genus *Anchusa*, of which three species are common in Britain.

Alkan'na. See HENNA.

Alkarsin. See CACODYL.

Al Kasr al Kebir, Moorish name for Alcazar-Kebir (q.v.).

Al-Kindi. See ARABIAN LANGUAGE.

Alkmaar, an old town of the Netherlands, on the North Holland Canal, 19 miles N. by W. of Amsterdam by rail. It is well built, has very clean streets, and is intersected by broad canals. It possesses a Gothic town-house; the church of St Lawrence dates from the 15th century. Alkmaar has manufactures of sail-cloth, sea-salt, soap, vinegar, and leather, and trade in cattle, grain, butter, and excellent cheese—of which it exports enormous quantities. Alkmaar held out against the Duke of Alba, who besieged it in 1573. Here, on October 18, 1799, the Duke of York signed a not very honourable capitulation. Pop. 22,000.

Alkoran. See KORAN.

Allah (compounded of the article *al* and *ilah*—i.e. 'the god,' a word cognate with the Hebrew *Eloah*), the Arabic name of the supreme god amongst the heathen Arabs, adopted by Mohammed for the one true God. See MOHAMMED, MOHAMMEDANISM.

Allahabad ('city of God'), the seat of the government of the United Provinces of Agra and Oudh, occupies the fork of the Ganges and Jumna, thus forming the lowest extremity of the *Doab*, or the country of *Two Rivers*, 390 miles SE. of Delhi. The situation of Allahabad, at the confluence of the holy streams of India, besides giving the city its sacred appellation, has rendered it a much-frequented place of pilgrimage for the purposes of religious ablution. With the exception of a few ancient monuments of elaborate and tasteful workmanship, the native part of the city consists of mean houses and narrow streets; the European quarter is vastly superior. The nucleus of the city appears to have been the native fort, which, on the east and south, rises directly from the banks of both rivers, while towards the land its artificial defences are of great strength. The Europeans of the garrison occupy well-constructed barracks. Beyond the fort are the cantonments for the native troops. There are numerous handsome villas and bungalows, rendered still more attractive and agreeable by avenues of trees.

A stronghold has existed at the junction of the rivers from the earliest times, but the present fort and city were founded by Akbar in 1575. The Mahrattas held Allahabad from 1736 till 1750; the city and district were ceded to the British in 1801. On the 6th of June 1857, the insurrection, which had begun at Meerut on 10th May, extended to Allahabad. Though the Europeans continued to hold the fort, yet the mutineers were, for some days, undisputed masters of all beyond; and between the ravages of the marauders and the fire of the garrison, the city soon became little better than a heap of blackened ruins. General Neill arrived on the 11th, and recovered Allahabad on the 18th; Havelock arrived shortly afterwards.

The position of Allahabad renders it naturally a centre of commerce and civilisation. It commands the navigation both of the Ganges and of the Jumna. It is on the direct water-route between Calcutta and the Upper Provinces; and is a main station, not only on the Grand Trunk Road, but also on the East Indian Railway. The most noteworthy buildings are the great mosque and the Sultan Khosrow's caravanserai—a fine cloistered quadrangle. The fort is of red stone, and is approached by a very handsome gate: it contains the famous pillar of Asoka (240 B.C.). Near by is the temple covering the undying banian tree; it is said to communicate with Benares by a subterranean passage, through which flows a third holy river, the Saraswati, visible only to the eye of faith. Allahabad possesses the gov-

ernment offices and courts, Roman Catholic cathedral, Mayo Memorial and town hall, a free public library, an institute, post and telegraph offices, an hospital, theatres, bazaars, &c. The Muir Central College, instituted by Sir W. Muir, was opened in 1886; and a university, instituted in 1887, immediately became the great educational centre of the province. A great fair is held annually in December and January, which lasts for a month, and is visited by about 250,000 persons. The cotton, sugar, and indigo produce of the fertile district of Allahabad is brought in large quantities into the city. There is a good local trade in gold and silver ornaments, and in European furniture. Allahabad is distant from Calcutta, by land, 564 miles, and 89 from Benares. The Indian National Congress has repeatedly held its sittings in Allahabad (as in 1888 and 1893). The town is a considerable mission centre. Pop. (1872) 143,693; (1881) 148,547; (1901) 175,748; (1921) 155,970, of whom about 50,000 were Mohammedans.

ALLAHABAD district is 85 miles in length by 50 in breadth; area, 2800 sq. m. The district is mainly agricultural, is well watered, and vegetation is luxuriant. Allahabad is the headquarters district of a division which has an area of 13,746 sq. m.

Allamanda, a tropical American genus of Apocynaceæ (q.v.), cultivated in hothouses for the sake of its large beautiful yellow flowers. *Allamanda cathartica*, a native of the West Indies, has violently emetic and purgative properties.

Allan, DAVID, a Scottish painter, Wilkie's fore-runner, was born at Alloa in 1744. From 1755 to 1762, he studied at the academy for painting and engraving established in Glasgow by the printer Foulis; and in 1764 the liberality of friends enabled him to go to Rome, where he resided sixteen years. There in 1773 he gained the gold medal of St Luke's Academy for the best historical composition. His subject was the 'Origin of Painting, or the Corinthian Maid drawing the Shadow of her Lover.' This picture, the highest effort of Allan's powers, was engraved by Cunego, and is now in the National Gallery at Edinburgh. In 1777 Allan came to London, where he painted portraits; in 1780 he removed to Edinburgh, and in 1786 succeeded Runciman at the head of the art academy there. His works subsequent to this date were chiefly of a humorous description, and illustrative of Scottish domestic life. His illustrations of Allan Ramsay's *Gentle Shepherd* became very popular, but are of no great merit. He died at Edinburgh, 6th August 1796.

Allan, SIR WILLIAM, a distinguished Scottish historical painter, was born at Edinburgh in 1782, and educated at the High School. Having early displayed a taste for drawing, he was apprenticed to a coach-painter, and studied at the Trustees' Academy, with Wilkie for a fellow-pupil. He subsequently entered the schools of the Royal Academy of London, and in 1803 exhibited 'A Gipsy Boy with an Ass,' but in 1805 he set out for St Petersburg, where the friendly interest of his countryman, Sir Alexander Crichton, the imperial family physician, soon procured him employment. In the Russian capital he spent several years, making occasional tours to the south of Russia, the Crimea, Turkey, and Circassia. In 1814 he returned to Edinburgh, and next year exhibited his 'Circassian Captives,' which, thanks to Sir Walter Scott, was sold by subscription for 1000 guineas. After a severe attack of ophthalmia, he visited Italy, Turkey, Greece, and Asia Minor. In 1826 he was elected an Associate of the London Academy; in 1835, an Academician. In 1838 he became president of the Royal Scottish Academy,

and on Wilkie's death in 1841, he was knighted and appointed Limner to Her Majesty for Scotland. He died in his painting-room, 22d February 1850. Though not a great painter, Allan gave such an impulse to historical painting, especially of national subjects, as entitles him to a high place in the history of Scottish art.

Allantois, a sac-like foetal membrane formed in the embryos of reptiles, birds, and mammals, as an outgrowth from the posterior end of the alimentary tract, just in front of the anus. While it never really occurs in animals lower than reptiles, it may be fairly said to be represented in the fish *Lepidostiren* and in the amphibia by a urinary bladder. In all higher animals, however, it is precociously developed and modified for other purposes. It forms a large sac, enveloping the embryo outside the Amnion (q.v.). In reptiles and birds the surface is traversed by an abundant network of blood-vessels, and the important function of embryonic respiration is thus discharged. In placental

Foetal Membranes of a Mammal :

E, embryo; M, its middle layer or mesoderm; H, gut-cavity lined by inner layer or endoderm; U.V., umbilical vesicle; al, allantois, with allantoic cavity, A.L.C.; am, amnion, with amniotic cavity, A.C. am represents the united inner portion of double folds, the outer limbs of which form the sub-zonal membrane (not lettered) under pc, the zona pellucida. (From Turner.)

mammals a further functional change (see FUNCTION) is exhibited, since the allantois aids in the development of the chorion, and this again is intimately connected with the walls of the uterus, in the structure known as a *Placenta* (q.v.). The blood of the embryo is exchanged with the blood of the mother, and embryonic nutrition is thus effected. The precocious urinary bladder is thus respiratory in reptiles and birds, and nutritive in mammals. In amphibia, the allantois persists as stated; in reptiles, the stalk dilates to form the permanent bladder; in birds, the whole atrophies. In mammals, the stalk of the allantois (1) dilates to form the bladder, while the lower portion (2) narrows to form the *urethra*. The *urachus*, or stalk connecting the bladder to the ventral wall of the body, is also of allantoic origin.

Allard, JEAN FRANÇOIS, was born in 1785, and in 1815 was adjutant to Marshal Brune (q.v.), after whose assassination he quitted France, intending to emigrate to America. Having changed his plan, he entered the service of Abbas-Mirza of Persia, and in 1820 proceeded to Lahore. There Runjeet Singh made him generalissimo of the Sikh army, which he organised and trained in the European modes of warfare. In 1833 he revisited Paris, was received with distinction, and made French *chargé d'affaires* in Lahore. Having distinguished himself in the battles of Runjeet Singh with the Afghans, he died at Peshawar, 23d January 1839.

Alleghany, a manufacturing town of New York, 70 miles S. by E. of Buffalo; pop. 2000.

Alleghany, or ALLEGHENY, a river which, rising in Pennsylvania, unites with the Monongahela at Pittsburg to form the Ohio. Though it flows through a hilly country, yet it is navigable for nearly 200 miles above Pittsburg, whence by the Ohio and the Mississippi the navigation extends to the Gulf of Mexico.

Alleghany Mountains, a term sometimes used as synonymous with the Appalachian system (see APPALACHIANS), but by some writers applied only to that portion of the system which extends from Pennsylvania to North Carolina, and which forms the watershed between the Atlantic and the Mississippi. It is sometimes used in a still more restricted sense. The ridges are remarkable for their parallelism and regularity, all the main valleys being longitudinal. The general direction is nearly parallel with the Atlantic coast. Their average height in Pennsylvania and Virginia is from 2000 to 2400 feet above the sea; but their original height has been greatly reduced by denudation or erosion. They are composed of stratified rocks of the Silurian, Devonian, and Carboniferous ages. They are rich in coal, iron, and limestone, and their forests supply large quantities of valuable timber.

Allegheny, or ALLEGHENY, now a portion of Pittsburg, but till 1907 ranking separately as one of the chief manufacturing cities of Pennsylvania, situated on the Alleghany River, opposite Pittsburg proper, is the terminus of important railway lines, and has besides its factories numerous important public institutions, such as the Western Penitentiary, a Carnegie Public Library, a Presbyterian theological seminary and other theological schools, an astronomical observatory, a Catholic orphanage, and a college for coloured persons. The chief industries of the place include rolling-mills for iron, cotton and woollen mills, breweries, foundries, a steel factory, blast-furnace, and locomotive works. It is a favourite place of residence for the business men of Pittsburg; but, though in many respects a suburb of that city, it had a separate municipal organisation till 1907. Pop. (1880) 78,681; (1890) 105,287; (1900) 129,896; (1906) 145,240. See also ALLEGANY, ALLEGHENY.

Allegiance is derived from the Old French *lige*, and is closely connected with the word *liege*, being the relation of a liege-man to his liege-lord. 'Allegiance,' says Blackstone, referring it to another source, 'is the tie or *ligamen* which binds the subject to the sovereign, in return for that protection which the sovereign affords the subject.' Allegiance is the highest legal duty of a subject, and consequently its violation, Treason (q.v.), is the highest legal offence. Allegiance is of three kinds. (1) *Natural allegiance* is such as is due from natural-born subjects and also from persons who become naturalised citizens. 'All subjects,' Sir Edward Coke explains, 'are equally bounden to their allegiance as if they had taken the oath; and the taking of the corporal oath is but an outward declaration of the same.' In return for the protection which the state affords to its subjects, every subject, independently of any express promise, is bound to bear true allegiance to the sovereign of the state, and to defend the state from attack from without or from within. Persons entering on certain offices are required by law to take the *oath of allegiance* or an affirmation in lieu of the oath. The taking of the oath does not add to the natural duty of a British subject. The Promissory Oaths Act of 1868 abolished the separate oaths of allegiance, supremacy, and abjuration formerly required, and substituted therefor a simple promise of allegiance

to the king, his heirs, and successors. The oath is exacted, on acceptance of office, from the persons named in the schedule to the Act of 1868, from members of parliament, and from a few other persons. (2) *Acquired allegiance* is due from aliens becoming naturalised. Aliens who seek naturalisation are required to take the oath of allegiance. (3) *Local or temporary allegiance* is that obedience and temporary aid due by an Alien (q.v.) to the state in which he resides. If a resident alien commits an offence which in the case of a natural-born subject would amount to treason, he may be punished as a traitor. Local differs from the higher kinds of allegiance in this, that it endures only so long as the alien resides within the king's dominions, whereas natural allegiance, whether implied or expressed, is at common law perpetual in character. See ALIEN, NATURALISATION.

In the United States there is no personality to whom allegiance is due; the sovereignty resides in the combined will of the people, as expressed in the constitution and laws. Allegiance is twofold—(1) to the central government, which is paramount; (2) to the state of which one is a citizen. Children of citizens of the United States born without the limits of the country owe allegiance to the United States.

By the law of England, and agreeably to the spirit of the constitution, a usurper in actual possession of the crown, or king *de facto*, is entitled to allegiance, because he then represents, not the sovereign whom he has dispossessed, but the general will in which the ultimate sovereignty of England resides. The sovereign may by proclamation summon his subjects to return and take part in the defence of the kingdom, when menaced or endangered.

The papal pretensions at various times gave rise to difficulties with regard to the allegiance of Roman Catholics. The sentence of Pius V., renewed by Gregory XIII. and Sixtus V., deposing Elizabeth and releasing her subjects from all obligations of allegiance, led to increase of the rigour of the penal laws. Father Parsons boldly maintained that the deposing power was an article of the Catholic faith. In 1603, however, thirteen influential priests signed a protestation of allegiance to Elizabeth, in which they emphatically declared their readiness to defend their sovereign, in spite of all pretended excommunications, from any attempts to put in force such sentences. The declaration came too late for Elizabeth to take action upon it. But after the Gunpowder Plot, when parliament was enacting fresh penal statutes, James I., with a view of establishing a distinction between Catholics whose loyalty he could depend upon and those whose opinions rendered them dangerous, and of affording some small measure of relief to the former, framed in 1607 the famous Oath of Allegiance, which caused confusion and division in the Roman Catholic camp for nearly a century. James's object was conciliatory, but he defeated that object by requiring Catholics not merely to assert their own rejection of the deposing power, but to pronounce the doctrine held by many learned doctors and canonised saints of their church to be 'impious and heretical.' In 1690 the form of the oath was altered in a sense hostile to Roman Catholics, and it was not until 1778 that it was freed from all objection on their part. The definition of the pope's infallibility by the Vatican Council in 1871 gave occasion to a pamphlet by Mr Gladstone, entitled *The Vatican Decrees in their bearing on Civil Allegiance* (1874), which once more revived controversy.

The oath of abjuration was imposed in 1701 upon members of parliament and all holders of public offices, including clergymen, teachers, bar-

risters, solicitors, &c. It was a declaration in favour of King William and the Revolution Settlement, and against the 'late King James,' and concluded with the words, 'upon the true faith of a Christian.' The form of oath was altered in 1714, when the first Pretender had assumed the title of James III. and VIII.; and the scruples felt in Scotland as to whether the oath was consistent with the Treaty of Union were removed by statute. It was also at this time imposed on voters in Scottish elections. After special provision had been made for the case of Catholics, and of Quakers and other persons whose conscience prevented them from taking an oath, the oath of abjuration was remodelled in 1858, one form being substituted for the separate oaths of abjuration, supremacy, and allegiance, and either house of parliament being enabled, by resolution in individual cases, to dispense with the reference to Christianity. The new form was just a declaration of allegiance to the queen, a promise to support the Protestant succession, and a denial of the authority of foreign princes and prelates. The matter was afterwards separately dealt with in the Clerical Subscription Act, 1865; the Parliamentary Oaths Act, 1866; and the Offices and Oaths Act, 1867; but the law was consolidated by the Promissory Oaths Act, 1868. By this statute, a short oath of true allegiance, usable by Catholics and Jews, was substituted for the old oaths of abjuration, supremacy, and allegiance; an official oath of true service was provided for public officers other than judges; and a judicial oath of true service, and to do right without fear or favour, was provided for the judges. All these oaths concluded, 'so help me God;' which words, in the case of the oath of allegiance taken by members of parliament, gave rise to the famous Bradlaugh case. The Oaths Act of 1888 enables any person who objects to being sworn to make an affirmation, whenever and wherever the taking of an oath is required by law. See ALIEN, CATHOLIC EMANCIPATION, JEWS, OATH, PARLIAMENT.

Allegory (Gr., made up of *allos*, 'other,' and *agora*, 'speaking'), a figurative representation, in which properties attributed to the apparent subject really refer to another subject not named but intended to be understood. It is supposed to be a figurative application of real facts. The New Testament *Parable* (q.v.) is a short allegory, marked by simplicity and brevity, and with one definite moral. Allegory differs from metaphor chiefly in its being longer sustained, and more fully carried out in its details; while metaphor is confined to a single expression or to a sentence or two, allegory runs through the whole representation. It is not abstract ideas alone that are adapted to allegorical treatment; not only may virtue and vice, for instance, be personified and treated allegorically, but real persons may be represented by allegorical persons. Nor is language alone the medium of allegory; it may be addressed to the eye, and is often exhibited in painting, sculpture, or the actor's art.

We find allegory in use from the earliest ages. Orientals are specially fond of it. As examples from antiquity may be cited the comparison of Israel to a vine in the 80th Psalm; the beautiful passage in Plato's *Phædrus*, where the soul is compared to a charioteer drawn by two horses, one white and one black; the description of Fame in the fourth book of the *Æneid*. In the mediæval literature of Europe allegory played a principal part, when almost every poet was an imitator of the *Roman de la Rose* of Guillaume de Lorris and Jean de Meung. Of later allegories Bunyan's *Pilgrim's Progress* is perhaps the most complete; Spenser's *Fæerie Queene*, Swift's *Tale of a Tub*, Addison's 'Vision of Mirza' in the *Spectator*, and

Thomson's *Castle of Indolence* are well-known examples. See Saintsbury, *Flourishing of Romance and Rise of Allegory* (1897); also APOLOGUE, BEAST-FABLES, FABLE.

ALLEGORICAL INTERPRETATION is that kind of interpretation by which the literal significance of a passage is either transcended or set aside, and a more spiritual and profound meaning elicited than is contained in the form or letter. The apostle Paul himself allegorises, or, at least, interprets spiritually the history of the free-born Isaac and the slave-born Ishmael (Gal. iv. 24). Allegorical interpretation with reference to the Old Testament was most extensively employed by Philo Judæus, a philosophical Jew of Alexandria, and a contemporary of Jesus. His writings stimulated the allegorising tendencies of the Alexandrian school of Christian theologians, the most famous of whom are Clemens Alexandrinus and Origen. The latter went so far as to say that 'the Scriptures are of little use to those who understand them as they are written.' Thus he maintained that the Mosaic account of the Garden of Eden was allegorical, that Paradise only symbolised a high primeval spirituality, and that the expulsion from the Garden lay in the soul's being driven out of its region of original purity. The Neo-Platonists allegorised the ancient myths. See EXEGESIS.

Allegretto, a movement somewhat slower than Allegro (q.v.).

Allegri, GREGORIO (1585?-1652), born in Rome, became a priest and member of the choir in the Sistine Chapel, and composed concertos, motets, and especially the famous *Miserere* for nine voices, annually performed in the Sistine Chapel.

Allegro (It., 'lively'), in music, implies that a piece or passage is to be performed in a quick or lively style. An allegro may be a whole piece of music, or a movement (usually the first) of a symphony, sonata, quartet, or the like.

Alleine, JOSEPH, next to Baxter the most widely read of the Puritan writers, was born at Devizes early in 1634. He was educated at Lincoln and Corpus Christi Colleges, Oxford, where he was noted for the severity of his studies, and was ordained in 1654. He began his ministry at Taunton in the same year, and laboured there until his ejection with the two thousand in 1662. Together with the grandfather of the Wesleys, he now became an itinerant preacher, and was in consequence frequently fined and imprisoned. His last years were dark and troubled, but death brought him relief, 17th November 1668. He was buried according to his wish in the chancel of his old church at Taunton. His *Alarm to the Unconverted*, of which 20,000 copies were sold at once on its appearance (1672), and 50,000 on its republication under a new title three years later, is still deservedly read. His interesting *Remains* were published in 1674.

Alleluia. See HALLELUJAH.

Allemande is a German national dance (hence the French name, meaning 'German'), originally Swabian, in various kinds of waltz tempo. It was introduced into France in the time of Louis XIV., and became extremely popular on the stage under Napoleon I. The name has also been used for a lively German folk-dance in two-four time, and especially for an orchestral composition in slow and measured time, not for dancing. This last forms a movement in suites.

Allen, BOG OF, a series of morasses east of the Shannon, in King's and Queen's Counties and Kildare, Ireland, comprising about 150,000 acres, interrupted by strips of arable land.—**LOUGH ALLEN**, in Leitrim, is a lake on the upper course of the Shannon (q.v.), and has an area of 8900 acres.

Allen, CHARLES GRANT, born at Kingston, Canada, February 24, 1848, graduated in 1870 from Merton College, Oxford. In 1873-77 he was first professor, then principal, of a college at Spanish Town in Jamaica, and he afterwards settled in England. He wrote *Physiological Aesthetics* (1877); *Colour Sense*; *The Evolutionist at Large*; *Vignettes from Nature*; *Flowers and their Pedigrees*; *The Evolution of the Idea of God* (1897); *Darwin* (1885); *Force and Energy* (1888); besides a long series of novels, including *Philistia* (1884), *Babylon*, *In All Shades*, *A Terrible Inheritance*, *This Mortal Coil*, and *The Great Taboo* (1890). *The Woman who Did* (1895), a novel with a purpose, evoked a storm of controversy. He wrote much for periodicals and contributed to *Chambers's Encyclopædia*. He died at Hyndhead, 25th October 1899. See *Life* by E. Clodd (1900).

Allen, ETHAN (1738-89), born at Litchfield, Conn., took part in the capture of Fort Ticonderoga (1775), and did good service in Montgomery's expedition to Canada, but was taken prisoner, and not exchanged till 1778. A member of the Vermont legislature, he wrote a deistical work (1784). See *Life* by De Puy (1853).

Allen, JAMES LANE, born in Kentucky in 1849, lectured in Kentucky University, but made a name as a novelist by a series of tales of life and nature in Kentucky—amongst them *The Choir Invisible* and *The Reign of Law*.

Allen, JOHN (1771-1843), was born near Edinburgh, graduated M.D. at Edinburgh, travelled with Lord and Lady Holland, was an *habitué* of Holland House, and became warden and master of Dulwich College. He translated Cuvier, contributed largely to the *Edinburgh Review*, and wrote a famous treatise on the royal prerogative.

Allen, RALPH (1694-1764), son of a Cornish innkeeper, made a fortune by a lease of the posts (see POST-OFFICE), and for his varied benevolence was immortalised by Fielding as 'Squire Allworthy,' and by Pope. His home was Prior Park, near Bath. See *Life* by Peach (1895).

Allen, WILLIAM, Cardinal, was born of gentle parentage at Rossall, Lancashire, in 1532, and in 1547 entered Oriel College, Oxford, of which, in 1550, he was elected fellow. In 1556 he became principal of St Mary's Hall, and Catholic though he was, he retained this office till 1560; nor was it till the following year that he had to seek refuge in Flanders. Even then he stole back home in 1562, that his native air might cure a wasting sickness; but when, in 1565, he landed once more in the Low Countries, it was never to return to England. He received priest's orders at Mechlin, in 1567 made a pilgrimage to Rome, in 1568 founded the English college at Douay (q.v.), and in 1587 was created a cardinal during his fourth visit to Rome. He never afterwards quitted the imperial city, dying there on 16th October 1594. At the time of the Armada, Allen signed, if he did not pen, the *Admonition to the People of England*, in which he declared Elizabeth to be deposed, and urged the Catholics to take up arms against her. He possessed, in addition to moral and intellectual gifts of a high order, a remarkable personal influence, which made him as long as he lived the unrivalled leader of his co-religionists. The decadence of the Catholic cause dates from his death. But his college at Douay was perhaps the chief means of preserving the Catholic faith from being so utterly destroyed in England as it was in the northern kingdoms of the Continent. He wrote several works on the religious and political controversies of his time, the chief of which are his *Apology for the Seminaries* (1581), described by Bolton as 'a princely, grave,

and flourishing piece of natural and exquisite English, and a *Modest Defence of English Catholics*, in answer to Cecil's *Execution of Justice*. See his *Letters and Memorials*, edited by Fathers of the Oration, with introduction by Dr Knox (1882), and Martin Haile, *An Elizabethan Cardinal* (1914).

Allenby, SIR EDMUND, first Viscount Allenby (1919), field-marshal, born in 1861 at Brackenhurst, near Southwell, Nottinghamshire, served in Bechuanaland, in Zululand, and in the Boer war. In the European war he commanded cavalry in France; and as commander-in-chief of the Egyptian Expeditionary Force he took Beersheba and Gaza (1917), and won a decisive victory over the Turks in Palestine in September 1918. In 1919-25 he was High Commissioner for Egypt. See JERUSALEM.

Allenstein, a town of East Prussia, 65 miles S. of Königsberg, has a mediæval castle; pop. 33,000. Allenstein and district decided by plebiscite in 1920 to remain German.

Allentown, a manufacturing town of Pennsylvania, in a fertile district on the Lehigh River, 60 miles NW. of Philadelphia by rail. The Lehigh Valley is rich in iron ore and anthracite coal; large blast-furnaces, ironworks, and rolling-mills are in operation in the neighbourhood; and there are manufactures of furniture and linen thread. The inhabitants are mostly of German descent. Allentown possesses a Lutheran college, a female college, an academy, a military institute, and a Lutheran seminary. Pop. (1860) 8025; (1880) 18,063; (1900) 35,416; (1910) 51,913; (1920) 73,502.

Alleppi. See AULAPOLAI.

Allerion, in Heraldry, an eagle with expanded wings, but without beak or feet. The best-known examples of it are in the arms of the duchy of Lorraine, and of the family of Montmoency. In the earlier heraldry it has both beak and claws, and is described as a large species of eagle.

Alleyne, EDWARD, a famous actor, contemporary with Shakespeare, was born in 1566, and died in 1626. His connection with the English stage as partner and step-son-in-law of Philip Henslowe (q.v.) invests his life with interest to the student of the drama; but it is as the munificent and pious founder of Dulwich College (q.v.) that he principally claims the remembrance of posterity. The building of the college was begun in 1613, and in 1619 the institution obtained the royal charter, after some obstruction on the part of Lord Bacon, who wished the king to apply part of the grant to the foundation of two lectureships at Oxford and Cambridge. Alleyne himself and his wife took up quarters in the college, living on equal terms with the sharers of his bounty. See his *Memoirs* by Collier (1841); Collier's *Alleyne Papers* (1843); and Warner's *MSS. of Dulwich College* (1881).

All-Fools' Day. See APRIL.

Allia (more correctly, *Aha*), a small stream in ancient Latium, which fell into the Tiber, 11 miles N. of Rome. It was the scene of the defeat of the Roman army by the Gauls under Brennus in 387, or, according to others, 390 B.C.

Alliaceus Plants are primarily those of the genus *Allium* (Onion, Leek, Shallot, Garlic, Ramsons, Rocambole), or others nearly allied to it. The term is, however, extended to denote the possession of the characteristic odour and taste (due to the presence of an essential oil), presented in varying degrees by all members of that important genus. Thus the alliaceous flavour and odour are strongly developed in plants belonging to very different orders—e.g. the common treacle-mustard (*Alharia officinalis*, natural order Cruciferae)—while certain species of *Meliaceæ* are used as garlic in Java.

Alliance. See TREATY, HOLY ALLIANCE, LEAGUE, SUCCESSION WARS, TRIPLE ALLIANCE.

Allibone, SAMUEL AUSTIN, LL.D., bibliographer, was born in Philadelphia, April 17, 1816. At first engaged in mercantile pursuits, he was an earnest student of English literature, which bore fruit in 1853, when he began his *Critical Dictionary of English Literature and of British and American Authors* (3 vols. 1858-70-71), containing in all notices of 46,499 authors. The second and third volumes greatly surpassed the first in accuracy and completeness. In 1891 a supplement in two volumes, containing entries of 93,780 works, was published by J. Foster Kirk; beginning where the original work left off (in A to O in 1850, in O to Z in 1870; see BIBLIOGRAPHY). Dr Allibone also published an *Alphabetical Index to the New Testament* (1869); *Poetical Quotations* (1873); *Prose Quotations* (1876); *Great Authors of All Ages* (1879). In 1879 he became head of the Lenox Library, New York; and he died at Lucerne, 2d September 1889.

Allier, a department in the centre of France (named from the river Allier, which rises in Lozère, and flows 233 miles through Haute-Loire, Puy-de-Dôme, and Allier to the Loire below Nevers); area, 2848 sq. m.; pop. (1901) 421,074; (1921) 370,950. It is a hilly district, especially in the south, sloping down towards the river Loire in the north, and is partly woody, but generally well cultivated, producing the usual kinds of grain with wine and oil. It is also rich in minerals, especially iron, coal, antimony, manganese, and marble. The majority of the population is engaged in agriculture. Mineral springs are found at Vichy and elsewhere. The chief town is Moulins.

Allies, THOMAS WILLIAM, born at Bristol in 1813, passed from Eton to Wadham College, Oxford, where he obtained a first class in 1832. He became examining chaplain to Bishop Blomfield, who in 1842 presented him to the rectory of Launton, Oxfordshire. In 1850 he joined the Roman Catholic communion, and published the *See of St Peter*, accounting for his conversion. His marriage excluding him from the priestly office, he became secretary to the Catholic Schools Committee in 1853. He died 13th June 1903. Among his works were *Per Crucem ad Lucem* (1879), *The Throne of the Fisherman* (1887), *Monastic Life* (1896), &c. See *Life* by his daughter (1924).

Alligation, from a Latin word signifying 'to bind together,' is a rule in arithmetic which teaches how to solve such questions as the following: 3 lb. of sugar at 6d. are mixed with 5 lb. at 10d.; what is the price of a pound of the mixture? or: In what proportion must sugar at 6d. be mixed with sugar at 10d., to produce a mixture at 8½d.? The solution of the first is $\frac{3 \times 6 + 5 \times 10}{8 + 5} = 8\frac{1}{2}$ d.

In the second, the proportional number for one ingredient is the difference between the price of the other and that of the mixture; the number for the cheap sugar is therefore 1½, and for the dear, 2½, which are as 3:5, so that there must be 3 lb. at 6d. for every 5 lb. at 10d. If there are more than two ingredients, the problem becomes indeterminate—that is, it admits of a variety of answers. Thus: Of three metals, whose specific gravities are 10, 15, and 16, it is required to compose an alloy, whose specific gravity shall be 14. The conditions will be answered by mixing them in any of the following proportions: 1, 2, 1; 2, 2, 3; 6, 2, 11, &c.

Alligator (Span. *lagarto*, 'a lizard'), a genus of Crocodilia, the highest sub-class of reptiles. The alligator family (Alligatoridae) includes three genera—Alligator, Caiman, and Jacare, which differ from crocodiles in their shorter and broader

head; in their more unequal teeth; in the presence of pits on the upper jaw, which receive the first and fourth lower-jaw teeth; in the limited extent of the union between the two lower jaws, which does not extend backwards beyond the fifth tooth; in the separation between the scales of neck and back; and in other less notable characters. Generally, however, they resemble crocodiles both in habit and structure—e.g. in the lizard-like body, with powerful tail and short legs; in the bony armature of the skin; in the abundant teeth fixed in sockets; in the large head, with very solid skull and nostrils at the end of the snout; in the double ventricle of the Heart (q.v.); and so on. The alligators are now exclusively confined to the warmer parts of America, but fossil forms indicate a much wider distribution. They vary in size from 2 to 20 feet. The genus *Alligator* includes a few species, of which the most familiar is *Alligator lucius*, the pike-headed alligator of the Mississippi

Pike-headed Alligator (*Alligator lucius*).

region. The snout is broad, flattened, and rounded; the nostrils are separated by a prolongation of the nasal bone; the feet are webbed to about the middle; the bony plates of the back are not articulated together, and there are none on the ventral surface. There are twenty teeth on each of the upper and lower jaws. The lids of the gleaming eyes are fleshy and smooth. The genus *Caiman* is at home in tropical South America, but extends northward to Mexico. The nostrils are undivided, the webs of the feet are still more rudimentary, the bony plates of the back are articulated to form a connected armour, and there is also a ventral shield of jointed plates. The eyelids are strengthened by an internal bony plate, and there are twenty teeth on each jaw above, and twenty-two below. The *Jacare* closely resembles the *Caimans*, and is also South American. There are fewer teeth, rougher eyelids, and minor differences of little importance. All these forms occur abundantly in the rivers, especially in quiet corners where the current is not too rapid. During the floods of the wet season they frequent adjacent basins, while in other circumstances they avoid the consequences of cold or drought by burying themselves in the mud and remaining torpid till the return of suitable conditions recalls them to active life. They feed for the most part on fishes, which they are said to stun with their tails; but many of them are extremely, and often unadvisedly, omnivorous. After seizing some land animal, such as sheep or pig, they frequently allow it to drown without relaxing their grip, and then return to the shore to eat it at leisure. While most of them seem timid and shy of man, especially when on land, they are sometimes emboldened by hunger to venture an attack. They are to a large extent nocturnal animals, and their loud harsh bellow is a familiar sound in the districts which they frequent. The

large eggs are laid on shore in a hollow in the sand, covered over with grass and reeds, and left to themselves and the sun's heat. As many as sixty may be laid in one nest, arranged in separate layers. The young are developed before the period of flooding, and are carefully tended by the mother alligator. In spite of this, the majority probably fall victims to large fishes, birds of prey, and hardened male alligators. The flesh of some forms (*Jacare*) is eaten by Indians and negroes. It has a musky flavour, and this smell is also very characteristic at pairing time. An alligator oil, said to burn well, is also utilised; and the tough skin forms a strong leather, useful for saddlery and other purposes. Fossil remains prove the ancient standing of the alligator family.

Alligator Apple. See CUSTARD APPLE.

Alligator Pear. See AVOCADO PEAR.

Allingham, WILLIAM, a popular poet, of English origin, born at Ballyshannon in Ireland in 1824. He contributed to the *Athenæum*, *Household Words*, and other journals, while doing the duties of a commissioner of taxes in London, and in 1874 he succeeded Froude as editor of *Fraser's Magazine*. His first volume of poems appeared in 1850; his second, *Day and Night Songs*, in 1854, and in an enlarged form, illustrated by Rossetti and Millais, the year after. In 1864 first appeared in book form *Laurence Bloomfield in Ireland*, a narrative poem of nearly 5000 lines, in decasyllabic couplets, on contemporary Irish life. He published in 1877, *Songs, Ballads, and Stories*, a collection of new pieces, together with revised versions of earlier poems; and in 1887, *Irish Songs and Poems*. In 1874 he married Helen Paterson, who, born in 1848, made herself a name by her book-illustrations and her water colours. Allingham died 18th November 1889. His *Diary* was published by his wife in 1907.

Alliteration is the frequent occurrence in a composition of words beginning with the same sound. In Old German, Anglo-Saxon, and Scandinavian poetry, alliteration took the place of rhyme. This kind of verse, in its strict form, required that in the two short lines forming a couplet three words should begin with the same sound, two in the first line or hemistich, and one in the second; as in the following couplet of Anglo-Saxon poetry:

*Firum foldan
Frea almihtig* — CÆDMON.

Alliterative poems continued to be written in English after it had assumed its modern form; the most remarkable example is *Piers the Plowman*, a poem of the 14th century, of which the following is a specimen, the two hemistichs being written in one line:

*Mercy hight that maid, | a meek thing withal,
A full benign burd, | and buxom of speech.*

Even after the introduction of rhyme, alliteration continued to be largely used as an embellishment of poetry. Shakespeare ridicules the excessive use of it by many poets of his time in *Midsummer-Night's Dream* (V. i. 147), where he makes Quince say in his prologue:

*With blade, with bloody blameful blade,
He bravely broach'd his boiling bloody breast*

In *Love's Labour's Lost* (IV. ii. 57) he burlesques it again, making Holofernes 'something affect the letter, for it argues facility;' and Sidney, in his *Astrophel and Stella*, 15, thus addresses poets given to its use:

*You that do Dictionaries' method bring,
Into your rimes, running in rattling rows.*

Poets in all times have employed it for the sake of the point and emphasis it often gives a line. The satirist Churchill speaks of himself as one

*Who often, but without success, had prayed
For apt alliteration's artful aid*

He had prayed without success on this occasion, for the appearance of alliteration here is an illusion of spelling. A fine example of its effect in poetry occurs in the well-known lines of Coleridge (*The Ancient Mariner*):

The fair breeze blew, the white foam flew,
The furrow followed free

But the perfect ear of that consummate master of rhythm could tolerate only its occasional use. Shakespeare was himself a master of alliteration in its proper use, and as a poetical device it has survived to our own day.

But alliteration is not confined to verse; the charm that lies in it exercises great influence on human speech generally, as may be seen in many current phrases and proverbs in all languages, as 'life and limb,' 'house and home,' 'kith and kin,' 'Land und Leute,' &c. It often constitutes part of the point and piquancy of witty writing. Among modern writers this application of alliteration is perhaps most felicitously exemplified by Sydney Smith, as, when in contrasting the conditions of a dignitary of the English Church and of a poor curate, he speaks of them as 'the Right Reverend Dives in the palace, and Lazarus-in-orders at the gate, doctored by dogs and comforted with crumbs.'

In the early part of the 17th century, the fashion of hunting after alliterations was carried to an absurd excess; even from the pulpit, the chosen people of God were addressed as 'the chickens of the church, the sparrows of the spirit, and the sweet swallows of salvation.'

See Professor Skeat's elaborate essay prefixed to vol. iii. of the reprint of Bishop Percy's *Folio Manuscript* (1868); Guest's *English Rhythms* (2d ed. by Skeat, 1882); Schipper's *Englische Metrik* (1895).

Allium, a genus of Liliaceæ (q.v.), containing about 250 species. These are perennial, or more rarely biennial, herbaceous plants, usually producing tunicated bulbs by their thickened and concentric leaf bases, and are natives chiefly of the temperate and colder regions of the northern hemisphere. Garlic, Onion, Leek, Shallot, Chive, and Rocambole (q.v.) are species of this genus in common cultivation. A number of other species are occasionally used on account of their characteristic nutritive and flavouring qualities in different countries. Nine species are natives of Britain, of which the most common is *Allium ursinum*, Ramsons or Wood-garlic, a species with much broader leaves than most of its congeners. It is most frequently found in moist woods and hedge-banks; but occasionally in pastures, in which it proves a troublesome weed, communicating its powerful odour of garlic to the whole dairy produce. Crow Garlic (*Allium vineale*), another British species, is occasionally troublesome in the same way, in drier pastures. Both are perennial, and to get rid of them their bulbs must be perseveringly rooted out when the leaves begin to appear in spring.

Alloa, a seaport town in Clackmannanshire, on the left bank of the tidal Forth, 6½ miles E. of Stirling, and 35 WNW. of Edinburgh. Among its buildings are the county court-house (1865), the handsome new town-hall (1888), the corn exchange (1862), and the parish church (1819); and its special feature is the Lime-tree Walk (1714), leading up from the harbour. It is an active centre of trade and manufactures, the latter including whisky, ale, woollen yarn, glass, iron; there is some shipbuilding, and coal is exported from pits in the neighbourhood. The harbour is fair, having been greatly improved in 1863. The Forth is here crossed by a railway viaduct (1885), and there is steam-communication by the river with Edinburgh. Close by is Alloa House (1838), the seat of the Earl of Mar and

Kellie, with Alloa Tower, 89 feet high, and built about 1223. Here Queen Mary spent part of her childhood, as also did James VI. and Prince Henry. Pop. (1841) 5443; (1911) 11,893; (1921) 12,421.

Allobroges, a Celtic race of Gaul, whose territory lay between the Isère, the Lake of Geneva, and the Rhone, corresponding to the later Dauphiné and Savoy. Their chief town was Vienna (Vienne); their frontier town against the Helvetii, Geneva. First heard of as allies of Hannibal at the time of his invasion, 218 B.C., they were subjected to the Roman yoke in 121 by Quintus Fabius Maximus, thence called *Allobrogicus*, and from that time were governed as a part of Gallia Narbonensis. But they were civilised with difficulty, and were ever ready for rebellion.

Allocution, the address delivered by the pope at the College of Cardinals on any ecclesiastical or political circumstance. The Papal court generally makes use of it to guard a principle which it is compelled to give up in a particular case, or to reserve a claim for the future which has no chance of recognition in the present. Allocutions are published by being affixed to the doors of St Peter's.

Allo'dium, or ALLODIAL TENURE, has no well-defined general meaning in Law. It refers to a primitive form of land-tenure, which, both in Celtic and Teutonic communities, seems to have succeeded the original shifting allotment among the members of the tribe, the *sors* of the Burgundian law. The allod, udal, or ducas was an untaxed freehold held by custom or 'folk-right.' In Scandinavia its owner was the Holder, in Ireland the Brugaídh, in some parts of Germany the Bonder, in Kent the Gaveler. The allod was in some places inalienable, except in cases of starvation, and was not confiscated by the felony of the holder. Its most definite characteristic was freedom from the homage and other burdens which came in with the feud. Prior to feudalism, for instance, the land of France was either allodial or fiscal, under the official tenure of the *graphio*. The *franc alleu noble* was practically an allod conferred by a grant of *salica terra* or royal land. The extension of royal authority led to the system of benefices, and ultimately, under the influence of the Roman land doctrine of emphyteusis, to that of feus. Prior to the Conquest the land-tenure that existed in England was based on service and the comitatus of the king, and was therefore different from the developed Continental feudalism, of which the knight-service and the duties payable were the basis. But although the *boodland* of the Anglo-Saxons resembles the primitive allod, the latter had disappeared before the Norman Conquest. When the principal landholders of England surrendered their lands into the hands of the Conqueror at the council of Sarum, feudality was formally recognised, and it henceforth became a fundamental maxim in the law of real property that 'the king is the universal lord and original proprietor of all the lands in his kingdom, and that no man doth or can possess any part of it but what has mediately or immediately been derived as a gift from him, to be held upon feudal services' (Blackstone, vol. ii. p. 51, Kerr's edition). See FEUDALISM. This change was accomplished by private arrangements between the allodial proprietors and the prince, the former being anxious to exchange their nominal independence for the greater security enjoyed by the vassals of the sovereign, the latter being willing to receive them as dependants, for the sake either of their personal services in war, or latterly for the equivalents of these services, in money or the produce of the lands. The process by which an allodial owner put himself in a feudal relation to a lord is known as 'commendation.' In some countries feudality,

though general, was not universal; and allodial tenures consequently continued to subsist alongside of those originating with the crown. In this position was Denmark, and it is curious that the only examples of allodial tenures to be met with in Great Britain are the Udal rights in the islands of Orkney and Shetland, which formerly belonged to that country. These lands are generally held without written title, and entirely free from feudal services. By the law of Scotland, all property and superiorities belonging to the crown itself, and all churches, churchyards, manse, and glebes, the right to which is vested by the designation of the presbytery, are regarded as allodial. In the United States, although the word fee is in use, the feudal relation does not exist, and the title to land is essentially allodial. Every tenant in fee simple has a free and independent right of property in his land.

Allotments, small plots of land let to tenants for cultivation. The word is now generally applied to lands held by local authorities or other public bodies under the Allotments Acts for the purpose of letting in small parcels to the 'labouring population.' In 1790 the lord of a manor near Tewkesbury, observing that the occupants of certain cottages with a little land were marked by superior respectability, set apart 25 acres for the use of the poor; and in two years the poor-rates were reduced to 4d., as compared with 2s. 6d. to 5s. in surrounding parishes. In 1795 a select committee of the House of Commons reported favourably on the system, and in 1819 and in 1831 acts were passed for its extension; societies were also formed for the same object. The severe distress among the labourers, and the alarming rise of the rates under the old poor-law, forced the subject on the attention of landlords and legislature. Enclosure Acts provided that garden allotments should be reserved for the poor as compensation for the advantages lost to them through the enclosing of lands; but in 1868 it was proved by a government commission that 7,000,000 acres had been enclosed since 1760, with very scanty provision for the poor. From the General Enclosure Act of 1845 down to 1867, 484,893 acres were enclosed; and of this amount only 2119 acres were set aside for the poor. In 1882 an Allotments Act (known as Mr Jesse Collings' Act) was passed, which compelled trustees of charity lands to offer the land in allotments to the labouring class. Much has been done for the extension of the system by voluntary arrangement on the part of the landowners. In 1887 the Allotments Act was passed, which gave to local authorities compulsory powers for the acquisition of land for allotments. The powers conferred by that act were severely restricted; but these powers were gradually and very largely extended by the Allotments Act, 1890, the Local Government Act, 1894, and the Small Holdings and Allotments Act, 1907. These acts were revised and consolidated in the Small Holdings and Allotments Act, 1908, which is now the ruling statute. The necessary lands for allotments may be acquired by local authorities either by purchase or by hiring, and provision is made for land being hired or purchased either by agreement or by compulsion. If a local authority fail in its duty to provide allotments, the Board of Agriculture may transfer to a body, known as the Small Holdings Commissioners, the powers of the defaulting authority. Subletting of an allotment is forbidden. The holder of an allotment, on the expiry of his tenancy, has a right to compensation for improvements. The Board of Agriculture has issued 'Model Regulations' which are generally adopted. In view of the continued depopulation of rural districts, the decline of our agriculture, and the long-established divorce of the labourer from the land, the expediency of giving the

worker a larger interest in the soil of the country is generally admitted; and it has been found that the allotment system, when wisely applied, is beneficial to all concerned. The size of allotments varies greatly in different parts of the country. It is not compulsory upon a council to provide allotments exceeding one acre in extent; and one person is not entitled to hold allotments acquired under the acts which exceed five acres in extent. The powers of the Board of Agriculture and of local authorities to provide lands for allotments and small holdings have been greatly extended by the Land Settlement (Facilities) Act, 1919. The Acquisition of Land (Assessment of Compensation) Act, 1919, which provides a tribunal and rules for the assessment of compensation in respect of land compulsorily acquired, applies to the deterioration of the amount of rent or compensation payable for land authorised to be seized compulsorily under the Small Holdings and Allotments Act, 1908.

In Scotland the Land Settlement (Scotland) Act, 1919, is one of a series of statutes providing facilities for the acquisition of land for allotments, and for the constitution and regulation of small holdings.

See LAND LAWS, PEASANT PROPRIETORSHIP, CROFTER.

Allotropy is the peculiarity, which certain elements exhibit, of existing in two or more distinct modifications, which, although chemically identical, usually differ very much in their physical properties, such as colour, density, hardness, and so forth.

The element carbon, which is a constituent of the very numerous chemical compounds commonly called organic bodies, is known in several allotropic modifications. Of these, two crystalline forms occur in nature—the first, the widely distributed but comparatively rare diamond; and the second, graphite or black-lead, familiar to all as the substance used in the manufacture of the so-called lead pencils. These two forms of carbon occur, as has been said above, crystallised—the diamond, in forms related to the cube, while graphite crystallises in thin hexagonal plates; and they thus present an example of what chemists call *dimorphism*, or the occurrence of the same substance in two totally distinct crystalline forms, which are not geometrically related to each other.

Besides the two crystalline forms of carbon found in nature in an almost pure state (graphite usually contains at least a small proportion of impurities), the various kinds of wood and animal charcoal, and coke, consist of carbon in a more or less pure state. These latter kinds of carbon are called *amorphous*, because they have not any definite crystalline form.

It is almost needless to point out the entire difference from each other in regard to colour, transparency, hardness, and other physical properties of the diamond and of graphite, diamond being, when quite pure, colourless and transparent, and the hardest of known substances; while graphite is black and opaque, and sufficiently soft to mark paper easily. That the various forms of carbon are chemically identical, is proved by burning any of them in oxygen, when in each case it is found that carbonic acid gas is produced and nothing else, and that exactly the same quantity of this gas is produced from equal weights of the various kinds.

In the case of many allotropic substances it is possible easily to convert one modification into another, but this is not markedly so in the case of carbon. When diamond is heated in the electric arc, out of contact with the air, it blackens and swells up into a somewhat coke-like mass. Many attempts have been made to prepare artificial diamonds from the more common kinds of carbon; and some measure of success has been attained by allowing carbon to separate, at a moderate tempera-

ture, from its solution in melted iron or silver, but the process is not remunerative.

Phosphorus presents another very good instance of allotropy. Several forms of this element have been described, but only two are commonly known. These are ordinary phosphorus, which is a pale yellow, semi transparent, waxy solid, soluble in carbon bisulphide, and crystallising from this solution in octahedra; and red or amorphous phosphorus, usually seen in irregular lumps or in powder as a dark, reddish-brown solid, which is really a mixture of at least two distinct modifications of phosphorus. Ordinary phosphorus is very readily oxidised in the air, and must be preserved under water to prevent its taking fire, and it is extremely poisonous. The amorphous variety does not undergo any change in the air at ordinary temperature, and it is not poisonous. When ordinary phosphorus is melted in close vessels, and kept for a long time at a temperature near its boiling-point, a certain proportion of it is converted into red phosphorus. This change is accompanied by the evolution of heat, as can be easily demonstrated by suitable experiment. From the mixture obtained, the red phosphorus can be separated by dissolving out the unchanged ordinary kind by means of carbon bisulphide. When heated to a temperature somewhat higher than that at which it was prepared, amorphous phosphorus changes back again into the ordinary kind. Most persons are familiar with the appearance of ordinary phosphorus as such. The brownish surface provided on the boxes of safety matches for igniting these consists mainly of amorphous phosphorus.

Sulphur, again, is known in several allotropic forms, some crystalline and some amorphous, which differ greatly in colour, melting-point, solubility in solvents, &c. Most of these forms are, however, unstable, and quickly begin to change back again into ordinary sulphur. One of the most remarkable varieties is the so-called plastic sulphur, familiar to many as the clear yellow or brownish, pliable and elastic mass obtained by pouring melted sulphur, at or near its boiling-point, into water. This soft condition does not continue long, as in a few days the substance becomes opaque and hard, and passes, in great part, into the ordinary form of sulphur again. This change may be hastened by heating the plastic variety to near the melting-point of ordinary sulphur, when it suddenly becomes solid, giving out in doing so sufficient heat to raise its own temperature several degrees.

Another instance of allotropy, and one of great interest, is the existence of oxygen in two forms—as ordinary oxygen and as ozone. Both forms are gases—oxygen odourless, while ozone possesses a peculiar and powerful odour. Ozone is believed to be constantly present in small quantity in country and sea air, but its mode of formation in the atmosphere is not yet known with certainty. Ozone is formed when an electrical machine is worked, and also during many chemical processes, as in the slow oxidation of phosphorus in moist air. It is best prepared by passing what is known as the silent discharge of electricity through oxygen, by which means a considerable proportion of the oxygen is converted into ozone. Ozone is a much more active oxidising agent than oxygen, and the property is attributed to it of destroying deleterious organic impurities in the atmosphere.

The nature of the difference between allotropic forms of the same substance is, to some extent at least, understood in the case of oxygen; ozone being a condensed form of oxygen, and having a density half as great again as oxygen. Whilst the molecule of oxygen is represented by the formula O_2 , that of ozone is represented by O_3 . It is probable that an analogous explanation may be found to account for

the formation of allotropic modifications of carbon, sulphur, phosphorus, &c.

Allotropy is nearly related to ISOMERISM, which see.

Alloway, Burns's birthplace, and the scene of his *Tam o' Shanter*, lies on the right bank of the 'bonny Doon,' 2 miles S. of the town of Ayr. The 'auld clay biggin,' in which the poet was born on 25th January 1759, was in 1880 converted into a Burns Museum. The 'haunted kirk' still stands, a roofless ruin, near the 'Auld Brig;' and hard by is the Burns Monument (1820).

Alloy. Compounds or mixtures which different metals form with one another are called alloys. There is an exception, however, in the case of mercury. When it is mixed with another metal, the compound is termed an *Amalgam* (q.v.). All alloys retain the essential properties of metals. They possess metallic lustre, and conduct heat and electricity well. On the other hand, when the metals form compounds with non-metallic elements, such as sulphur or chlorine, their general properties are quite changed. Alloys have been divided into three groups: (1) Those formed by the metals lead, tin, zinc, and cadmium, which impart to their alloys their own physical properties in the proportions in which they themselves are contained in the alloy. (2) Those formed by almost all other metals. Such alloys as belong to this group do not get imparted to them the physical properties of their constituent metals in the proportion in which they are present. (3) Those which contain metals found in both these groups of alloys.

In an alloy the specific Heat (q.v.) and the coefficient of expansion are always the means of those of its component metals. But in other physical properties a variation takes place. This is the case with specific gravity, which, in alloys of the first group, is the mean of their constituent metals; but in those of the second group, it is always greater or less than the mean specific gravity of their constituents. The increase in density indicates that the metals have contracted; in other words, that the metallic molecules have approached each other more closely; whilst the decrease in density denotes a separation of the molecules to greater distances from each other.

Again, in alloys of the first group, the conducting power for electricity is exactly proportional to the relative volumes of the component metals; while in alloys of the second group the case is different.

If lead, tin, zinc, or cadmium be mixed with any of the metals from which alloys in the second group are formed, this alloy has its coefficient of elasticity much increased. For example, coils of copper or silver wire are made straight by weights, by which a coil of brass or gun-metal wire will scarcely be altered in shape.

In some instances, when two melted metals are mixed together to form an alloy, an evolution of heat occurs, which is believed to indicate that a chemical compound has been formed. This is the case with copper and zinc, copper and aluminium, platinum and tin, &c. Many alloys, however, can be obtained in well-defined crystalline forms, which is usually considered a test of a definite chemical compound; yet a number of these—copper-zinc alloys, for example—crystallise in the same form, even when the proportions of the component metals vary considerably. Much has been learned in recent times by the study of polished and etched surfaces under the microscope.

A curious fact may be mentioned in regard to the solubility of alloys. Platinum by itself is quite insoluble in nitric acid, but if it be alloyed

with silver the compound is completely dissolved. Silver, on the other hand, readily dissolves in nitric acid, but it will not do so when mixed with a large quantity of gold.

The strength or cohesion of an alloy is generally greater than the mean cohesion of the metals contained therein, or even that of the most cohesive of its constituents. Thus, the breaking weight of a bar of copper or tin is very much lower than the breaking weight of a bar of the same size composed of certain alloys of tin and copper.

For alloys of iron (high-speed steels, stainless steel, &c.), see IRON AND STEEL, CHROMIUM, MOLYBDENUM, &c.

The most useful alloy in the arts is Brass (q.v.). This compound metal is next to iron in importance. Several kinds are made varying in composition from equal parts of copper and zinc, to five parts of copper with one of zinc. According to the proportions of these metals in the alloy it is called sheet-brass, Pinchbeck (q.v.), Dutch brass or Dutch Metal (q.v.), ordinary yellow brass, Muntz's metal or ship-sheathing brass, and so on.

There are some important alloys of copper and tin—among them Bronze (q.v.), Gun-metal (see CANNON), Bell-metal (see BELL), and Speculum Metal (q.v.). In these the proportions vary from equal parts of copper and tin, to ten parts of copper with one of tin. The most cohesive—that is, the strongest—of them is a bronze consisting of six parts of copper to one of tin. The addition of a little phosphorus to a bronze containing from 7 to 8 per cent. of tin gives it greater hardness, elasticity, and toughness. This alloy (phosphor-bronze) is much used for parts of machinery.

German Silver (q.v.) is an alloy composed, in its best quality, of two parts of zinc, four of copper, and one of nickel. Britannia Metal (q.v.) generally consists of about ninety-two parts of tin, eight of antimony, and two of copper. This is a softer metal than German silver, but both are largely manufactured into such objects as teapots, jugs, spoons, and the like, many of them being plated with silver. Nickel-copper alloys are used in the United States, Belgium, and Germany for coins.

Pewter is a tin alloy which was more used formerly than now. Its composition varies. Commonly, it consists of four parts of tin to one of lead, but sometimes it is tin with a little copper. Type metal (see TYPE) is an alloy of lead with antimony and some tin, but the proportions vary. Fusible metal melts at low temperatures; one kind is composed of three parts of tin, five of lead, and eight of bismuth, and melts in hot water. This alloy is now a good deal employed in stereotyping, and in obtaining copies of woodcuts. 'Albion metal,' which is largely used in some minor Birmingham manufactures, is an example of two metals combined by pressure, and therefore is not, strictly speaking, an alloy. It consists of tin laid on lead, the two metals being made to cohere by passing them between rollers. White, or anti-friction, metal, which has been much employed for certain kinds of machinery bearings, has in one variety a composition of eighty-five parts of tin, ten of antimony, and five of copper.

Aluminium-bronze (see ALUMINIUM), an alloy very closely resembling gold in appearance, which is much used for pencil-cases, chains, and some larger objects, varies in composition from ninety-five of copper and five of aluminium, to ninety of copper and ten of aluminium. A compound of silver and aluminium is sometimes used for watch-springs, and for spoons and forks. Dentists use a very ductile alloy composed of two parts by weight of silver and one of platinum. A metal formed of nine parts of platinum and one part of iridium was

employed for the standard metre-measures by the Parisian commission for the international metrical system. An alloy of osmium and iridium, which is not attacked by acids, is used for tipping gold pens, and sometimes also for the bearings of the mariner's compass.

Steeling silver consists of 11 oz. 2 dwt. of silver and 18 dwt. of copper in the troy pound. That is, it contains 7.5 per cent. of copper. The Coinage Act of 1920 (10 Geo. V. chap. 3) reduced the standard fineness of silver coins from this proportion to 50 per cent. The proportion of alloy in gold coin and plate is also regulated by law. It is well to state that an assayer or bullion-dealer uses the term *alloy* in a different sense from what may be called its common meaning. He would say that standard silver contains 18 dwt. of alloy in the pound troy; but the more general, or at least, the more scientific, way is to call it an alloy of silver and copper. It is the same with gold. Pure silver is too soft to be used for anything which is to be much handled. A little copper imparts to it greater hardness and toughness, and makes it more easily fusible. The alloy used for English is said to wear better than that used for any foreign silver coin, although the difference in one or two cases is small.

When gold is to be used for coins, jewelry, or plate, it requires to be alloyed with copper or silver, or with both, in order to harden it. Like silver, it is too soft when pure. There are five legal standards in Great Britain for articles made of gold—i.e. alloyed gold, apart from coin. These are called 22, 18, 15, 12, and 9 carat gold. That is to say, these figures represent the number of parts of pure gold in every twenty-four parts of the alloy used by the goldsmith or jeweller. English sovereigns are made of a mixture of twenty-two parts gold to two of copper, and this is called 22-carat or standard gold. In Germany, Italy, and the United States, standard gold for the coinage is 21.6 carats. Gold jewelry usually contains both copper and silver, and, according to the proportion of the constituents, the objects have different shades of yellow.

In the United States, it is declared by law that the standard for both gold and silver coins shall be such, that of a thousand parts by weight, nine hundred shall be of pure metal, and one hundred of alloy. Formerly it was provided that the alloy of gold coins might be of either copper or silver; but now only copper is used in the alloy either of silver or gold coins.

All-Saints' Bay, in the province of Bahia, on the coast of Brazil, forms a superb natural harbour, in which the navies of the whole world might ride at anchor. Its length from N. to S. is 37 miles; its breadth from E. to W. 27. The town of Bahia (q.v.) lies just within it.

All-Saints' Day, in Old English All-Hallows, All-Hallowmas, or simply Hallowmas, a church festival, introduced because of the impossibility of keeping a separate day for every saint. As early as the 4th century, on the cessation of the persecution, the Sunday after Easter was appointed by the Greek Church for commemorating the martyrs generally; and in the Church of Rome a similar festival was introduced about 610, when the old heathen Pantheon (the present Rotonda, or Santa Maria dei Martiri) was consecrated on 13th March. But the real festival of All Saints was first regularly instituted by Gregory IV. in 835, on 1st November. The choice of the day was doubtless determined by the fact that November 1, or rather the eve or night preceding it, was one of the four great festivals (1st February, 1st May, 1st August, and 1st November) of the heathen

nations of the north; for it was the policy of the church to supplant heathen by Christian observances. See BELTANE and HALLOWEEN.

Allsop, THOMAS (1795-1880), a native of Derbyshire and London stockbroker, was the 'helpful friend' of Coleridge and Lamb, and a sympathiser with Feargus O'Connor and Orsini. He published *Letters, Correspondence, and Recollections of Coleridge*.

Allsopp, SAMUEL (1780-1838), a member of the great brewing establishment of Allsopp & Sons, Burton-on-Trent, was a descendant of an old family, and was noted for the charities of his public and private life. He was succeeded in the business by his sons, Charles James, William, and Henry (1811-87). To the last of these the modern development of the firm is largely due. He represented Worcestershire in parliament (1874-80), and in 1880 was created a baronet. After his retirement, he was raised to the peerage under the title of Lord Hindlip of Hindlip and Alsop-en-le-Dale. In 1887 the concern was converted into a limited company.

All-Souls' Day, a festival of the Roman Catholic Church, which falls on 2d November. The object of it is, by prayers and almsgiving to alleviate the sufferings of the souls in purgatory. It was first instituted in the monastery of Clugny, 993, and is said to have originated thus: A pilgrim returning from the Holy Land, was driven by a storm on a rocky island somewhere between Sicily and Thessalonica. Here he found a hermit, who told him that among the cliffs of the island was situated the opening into the nether world, through which huge flames ascended, and the groans and cries of souls tormented by evil angels were audible. The hermit had also frequently heard the complaints and imprecations of the devils, at the number of souls that were torn from them by the prayers and alms of the pious; they were especially enraged, he said, against the abbot and monks of Clugny. The pilgrim on his arrival acquainted Odilo, abbot of Clugny, with what had come to his knowledge, and the abbot thereupon appointed the day after All Saints to be kept in his monastery as an annual festival for 'All Souls.' The observance in a short time became general, without any ordinance at large on the subject.

Allspice, a name frequently given to the kind of spice called Pimento (q.v.) or Jamaica pepper, the fruit of *Eugenia pimentata* and *E. acris*. The name originated in its being supposed to combine the flavour of different spices, particularly cinnamon, nutmeg, and cloves.

Allston, WASHINGTON, an American painter, was born at Waccamaw, South Carolina, in 1779. He graduated at Harvard in 1800, and went next year to London to study art at the Royal Academy under Fuseli. From 1804 to 1809 he resided in Rome, studying the old masters and attaining some distinction; and there he formed an intimacy with Thorvaldsen and Coleridge. After a short stay in America (1809) he once more visited England, and in 1811 gained the 200-guinea prize of the British Institution. In 1817 he went to Paris, and the year after returned to America, and permanently fixed his residence at Cambridge Port, near Boston, where he lived, cultivating his art and the muses, till his death on 9th July 1843. In 1819 he had been elected a London A.R.A. His pictures are very numerous, the best being scriptural subjects. A composition of great size, 'Belshazzar's Feast,' occupied from time to time the last twenty-five years of his life, but was left unfinished. Allston's style is noble, his ideas are imaginative, and many of his paintings evince a true poetic spirit. In colouring, he imitated the

Venetian school, and for this reason he has been styled 'the American Titian.' Coleridge said of Allston, that he was surpassed by no man of his age for artistic and poetic genius. He was author of a poem, *The Sylphs of the Seasons* (1813), the art-novel, *Monaldi* (1842), and *Lectures on Art* (ed. by Dana, 1850). See his Life by Flagg (1893).

All the Talents (MINISTRY OF). See GRENVILLE (WILLIAM WYNDEHAM, LORD).

Alluvion takes place where soil is added to land by a river or by the sea by imperceptible degrees. *Alluvio* in Roman law was a recognised mode of acquiring ownership, the effect being that the owner of the land to which such increment was made became owner of the increment. It was distinguished from *avulsio*, which takes place where a portion of ground is, by a sudden and violent flood, carried away from one man's land to another man's land; for in this case the ground so torn away remains in the ownership of the former proprietor. In English and Scots law these rules of Roman law are generally followed. In England land gained from the sea by gradual silting up, so as in time to make it *terra firma*, belongs to the owner of the adjoining land; but if the increment be sudden and considerable it belongs to the crown. In Scotland ground gradually silted up by the sea becomes the property of the owner of the adjoining land if, under his title or as a matter of fact, the boundary of his land is the sea or the flood-mark. In the United States an increment of soil on the shore of the sea or on the bank of a river, if gradually and imperceptibly made, goes to the owner of the land adjoining, in accordance with the principles of the Roman and English law.

Alluvium, a term originally applied to those deposits which were supposed to have been formed subsequently to the Flood, while Diluvium (q.v.) included the strata produced by it. In modern geological classification, these two terms have ceased to be used in this sense. By alluvium is now meant any earthy material deposited by the ordinary operation of water in motion. Hence it includes the mud, silt, sand, and gravel brought down by streams and rivers, and spread over lower lands, where it frequently forms flats and terraces. Some geologists extend the term to those wide accumulations of silt and mud which are formed in the upper reaches of estuaries, and laid bare at low tide. These are spoken of as *marine alluvium*. See DELTA, DENUDATION.

Allygurh. See ALIGARH.

Allyl (Lat. *allium*, 'garlic') is an organic radical, represented when in combination by C_3H_5 , and when in the free state by C_3H_{10} . The properties of some of its most important compounds are described in the article GARLIC (OIL OF).

Alma, a river in the Crimea, rising at the foot of the Tchadira Dag, and flowing westward into the Bay of Kalamita, about half-way between Eupatoria and Sebastopol. On the steep banks of this stream, through the channel of which the British troops waded amidst a shower of bullets, a brilliant victory was won on the 20th of September 1854, by the allied armies of Britain and France, under Lord Raglan and Marshal St Arnaud, over the Russian army commanded by Prince Menschikoff. It was the first battle of the Crimean war.

◀ **Almacantar**, a name for circles of altitude parallel to the horizon, and hence for an astronomical instrument for determining time and latitude. The almacantar consists of a telescope revolving on a horizontal axis, which can be clamped at any altitude, the whole resting on a float sustained in a trough of mercury. The clamped telescope, when its floating support is

turned, will therefore trace out a circle of equal altitude, and by the transits of stars across this circle, time and latitude can be obtained with very great accuracy. It can also be used for determining the apparent places of the heavenly bodies.

Almack's, a suite of assembly-rooms in King Street, St James's. They were built in 1765 by Almack, a tavern-keeper; but for a century (ladies were closed in 1890) they were known as Willis's Rooms, from the name of Almack's heir. The name is chiefly associated with the balls that, from the opening of the rooms till about 1840, were held there under the management of a committee of ladies of high rank; and the circle having admission to the balls at Almack's was at the beginning of the century regarded as the seventh heaven of the fashionable world. Willis's Rooms were also used for dinners and concerts. Almack seems to have been a Highlander called MacCaul or M'All, who transposed his name when he came to London as valet to a nobleman. Almack's *Club* (1764), where high play was indulged in, became Brooks's in 1778. See *Notes and Queries* for 1891. Almack died in 1781, leaving a large fortune to his family.

Alma da, a town of Portugal, in Estremadura, on a height opposite Lisbon; pop. 7000.

Almaden, or ALMADEN DEL AZOGUE ('the Mines of Quicksilver'), a town in Spain, 50 miles SW. of Ciudad Real, in the chain of the Sierra Morena; pop. 8000. Its rich quicksilver-mines, in twelve galleries one below the other, yield hundreds of tons annually. The present mines, which have been carried to a depth of 1200 feet, date from the 17th century; but quicksilver was largely worked here by the Romans in the time of Pliny. Crown property, they were rented by the Fuggers of Augsburg (1525-1645), and by the Rothschilds in the 19th century. Both cinnabar and native mercury occur.—NEW ALMADEN, in the Coast Range, California, 12 miles from San José, was first worked regularly for mercury in 1845, and used to yield as much as 2,000,000 lb. a year.

Almagest, the name given by the Arabs to the great work of the astronomer Ptolemy (q.v.).

Alma'gro, a town of New Castile, Spain, 13 miles ESE. of Ciudad Real. It has a great manufacture of lace. Pop. 9000.

Almagro, DIEGO DE, a Spanish *conquistador*, was born in 1464 or 1475, and was a founding who derived his name from the town near which he was found. After serving in the army, he sailed to seek his fortune in the New World, where he amassed considerable wealth by plunder, and became one of the leading members of the young colony of Darien. In 1522 he formed, with Pizarro, the design of conquering Peru—an undertaking crowned ten years afterwards with marvellous success. Receiving permission from the Spanish court to conquer for himself a special province south of Pizarro's territory, he marched on Chili in 1536, penetrated as far as the Coquimbo, and returned in 1537, just when the Peruvians had flown to arms and shut up the Spaniards in Cuzco and Lima. As these towns lay south of Pizarro's district, they were claimed by Almagro. He dispersed the Peruvian army before Cuzco, and advanced against Lima, hoping to make himself sole master of the country. But on the 6th April 1538, he was defeated in a desperate engagement with the Spaniards under Pizarro near Cuzco; and on the 26th, he was strangled in prison, and his corpse beheaded in the market-place of Cuzco. His half-caste son, Diego, collecting some hundreds of his father's followers, stormed Pizarro's palace, and slew him (1541); then proclaimed himself captain-general of Peru; but, defeated in the

bloody battle of Chupas (16th September 1542), he was executed along with forty of his companions.

Almali. See ELMALI.

Alma Mater (Lat., 'nourishing mother') is a name given to a university in relation to those who have derived instruction from it. The word *alma* ('nourishing,' 'kindly') was applied by the Latin authors to such of the deities as were friendly to men—Ceres, Venus, &c.—and also to the earth, the light, the day, wine, and the soil.

Almanac, a word applied in Roger Bacon's *Opus Majus* (1267) to permanent tables showing the apparent movements of the heavenly bodies. It is the Italian *almanacco* (about 1345), the French *almanach*, and the Spanish *almanaque*, the immediate source of all which, according to Sir J. Murray, was apparently a Spanish-Arabic *al-manākh*; an Arabic-Castilian vocabulary (1505) giving *manākh*, 'a calendar,' and *manah*, 'a sun-dial.' Further than this one cannot go, though attempts have been made to explain *manākh* from Semitic sources, and to connect it with the Latin *manacus* (properly *mēnæus*), 'a sun-dial,' of Vitruvius, or with the *almenichisaka* (in Eusebius, quoting Porphyrius), an Egyptian word signifying 'daily observation of things.' The *Fasts* (q.v.) of the Romans came nearer to our modern almanacs than the 'almanacs' known to Roger Bacon and Chaucer, for it was not till the 15th century that almanacs or *ephemerides* were prepared for definite periods, such as fifty or ten years; nor till the 16th for a single year. Thus, the earliest printed almanac was that *Pro pluribus annis*, published at Vienna in 1457 by the celebrated astronomer Purbach; whilst that printed at Nuremberg in 1473, by his pupil Regiomontanus, was for the thirty years from 1475 to 1506. The printer Engel of Vienna commenced the publication of an almanac in 1491; and Stofler of Tübingen, in 1524. Copies of these are now very rare. In 1533 Rabelais published, at Lyons, his almanac for that year, and renewed the publication in 1535, 1548, and 1550. The fame and popularity of the celebrated astrologer, Nostradamus (q.v.), gave such an impulse to the publication of predictions, that, in 1579, Henry III. of France prohibited the insertion of any political prophecies in almanacs—a prohibition renewed by Louis XIII. in 1628. Before this, in the reign of Charles IX., a royal *ordonnance* required every almanac to be stamped with the approval of the diocesan bishop.

Prophetic almanacs still circulate to an incredible extent in France, in the rural districts and among the uneducated. The most popular of all these is the *Almanach Liégeois*, a venerable remnant of superstition. It was first published at Liège in 1625, and ascribed to Matthieu Laensbergh, whose existence at any time seems very problematical. The *Almanach Liégeois* was a most convenient one for the illiterate, since by certain symbols attached to certain dates, the most unlettered persons could follow its instructions: thus the rude representation of a phial announced the proper phase of the moon under which a draught of medicine should be taken; a pill-box designated the planet most propitious for pills; a pair of scissors pointed out the proper period for cutting hair, a lancet for letting blood. Of course, amidst innumerable predictions, some may naturally be expected to come to pass. So in 1774, this almanac predicted that in the April of that year a royal favourite would play her last part. Madame Dubarry took the prediction to herself, and repeatedly exclaimed: 'I wish this villainous month of April were over.' In May Louis XV. died, and Madame Dubarry's last part was really played. The credit of old Matthieu was established more firmly than ever. In 1852 a number of

commissioners, appointed by M. Maupas, minister of police, having examined between 7000 and 8000 of the national chapbooks, which included a great number of almanacs, pronounced them so deleterious, that it became necessary forcibly to check their circulation.

In England, so far was any restraint from being put upon the publication of prophetic almanacs, or 'Prognostications,' as they were usually called, that James I. gave a monopoly of the trade to the two Universities and the Stationers' Company, under whose patronage, and with the *imprimatur* of the Archbishop of Canterbury, flourished such productions as Lilly's *Merlini Ephemeris* (1644-81), *Poor Robin's Almanac* (1664-1824), and *Moore's Almanac*, under the editorship of *Henry Andrews*, which reached an annual sale of more than half a million (1743-1820); yet 'it would be difficult to find, in so small a compass, an equal quantity of ignorance, profligacy, and imposture, as was condensed in these publications.' The memory of Partridge, from 1678 to 1713 the prophet of the Stationers' Company, is preserved in Pope's *Rape of the Lock*, and in Swift's lively burlesque, in which the prophet's own death was predicted. In 1775 a decision of the Court of Common Pleas, in favour of a bookseller named Carnan, abolished the monopoly of the Stationers' Company. In 1779 Lord North brought in a bill renewing their privileges. After a powerful speech against the measure by Erskine, who exposed the pernicious influence of the productions published under the monopoly, it was rejected. The Stationers' Company, however, still maintained their ground by buying up all rival almanacs; and it was not until the publication, in 1823, of the *British Almanac* by the Society for the Diffusion of Useful Knowledge, that the eyes of the English public became opened to the irrational and deleterious nature of the commodity which their own indifference or folly, as much as the selfishness of their purveyors, had hitherto maintained in existence. The success of this admirable publication stimulated the Stationers' Company to publish the *Englishman's Almanac*. The *British Almanac* itself has from 1870 been the principal almanac published by the Stationers' Company. *Whitaker's Almanack* is a valuable compendium of information, started in 1869, and now extending, with supplement, to about 1000 pages.

In Scotland the earliest almanacs seem to have been produced about the beginning of the 16th century. Shortly after the beginning of the 17th century, the almanacs or 'prognostications' published at Aberdeen had begun to enjoy a celebrity which is hardly yet extinct. About 1677 they were sold for a *plack* each; and the annual circulation amounted, on an average, to 50,000 copies. In 1683 appeared a rival publication, under the title of *Edinburgh's True Almanack, or a New Prognostication*. For a long time the Scottish almanacs continued, like all others of that age, to contain little besides a calendar, with a list of fairs, and—what constituted the great attraction—predictions of the weather. But something more instructive and comprehensive became requisite, and the *Edinburgh Almanac* seems to have been among the first to respond to this requirement of advancing civilisation; for, by various additions, such as a list of Scottish members of parliament, it had, in 1745, been extended from the original 16 pages to 36. In twelve years from that date, it had swelled to 72 pages; in 1779 it had reached 252 pages. Since 1837 it has been published under the title of *Oliver & Boyd's New Edinburgh Almanac*, and now extends to about 1300 pages. It contains an amount of information on all public matters, especially on those connected with North Britain, which, in its completeness, leaves little to

be desired. What *Oliver & Boyd's Edinburgh Almanac* is to Scotland, is *Thom's Irish Almanac* (1843) to Ireland—a work not less excellent, and even more extensive.

Of important national almanacs are the French *Almanach Royal*, afterwards *Impérial*, now *National*, begun in 1679, a bulky octavo volume, full of useful information; and the *American Almanac and Treasury of Fact*, a very meritorious publication, started in 1878. The earliest American almanac was published by William Bradford, at Philadelphia, in 1687. Franklin's *Poor Richard's Almanac* (1732-57) may be noticed.

The *Almanach de Gotha*, published annually at Gotha by the great geographical house of Justus Perthes, has a European, or rather a cosmopolitan character. It was begun in 1764, in the German language, in which it was continued until Napoleon I. became emperor, when it was changed to the French language; since the Franco-German war of 1871 it has been published in both tongues. The almanac is a small pocket volume, containing 1000 or 1200 pages of small type, and recording the sovereigns and presidents, and the present or late royal, mediatised, and noble families, of every civilised country, with the civil, diplomatic, military, and naval officers, a great amount of statistical information, compact summaries of constitutions, of international institutions, and other matters of political interest. No book ever printed contains so much political and statistical information in so small a compass. The extent, population, commerce, communications, shipping, emigration, and revenues, expenditures, and debts of states are given. The *annuaire diplomatique* contains the name of every diplomatic representative and *attaché* of Europe and America. The organisation of armies and navies in peace and in war is described with considerable detail. When the *Almanach de Gotha* was commenced, there was but one republic in existence—that of Switzerland. It was then little more than a register of the crowned heads and royal families of Europe. It has been slow to recognise political changes, and for years after the French Revolution, continued to print under the head of 'France,' Louis XVII. as the reigning monarch. It was not until Napoleon became emperor that his name found a place in its pages, and then his whole family was given, as with the other royal houses. During the Empire, Napoleon I. considered this little publication so important, that he exercised over it a rigid supervision, and in 1808, an entire edition, which had just been worked off, was seized because Anhalt took precedence of Bonaparte. To secure this rearrangement of the alphabet, the edition of that year was printed at Paris.

The most important astronomical almanac published in Britain is the *Nautical Almanac*, projected by the astronomer royal, Dr Maskelyne, and first published, with the authority of government, for 1767. After his death it gradually lost its character, and in 1830, in consequence of the numerous complaints made against it, the government requested the Astronomical Society to pronounce upon the subject. The suggestions of the Society were adopted, and in 1834 the first number of the new series appeared, with such additions and improvements as the advanced state of astronomical science rendered necessary. It is issued four years in advance of the year to which it refers. Still older than this almanac is the French *Connaissance des Temps*, commenced in 1679 by Picard, and now published under the authority of the *Bureau des Longitudes*. Its plan resembles that of the *Nautical Almanac*, but it contains a larger amount of original memoirs, many of them of great value. Similar works are the *Berliner Astronomisches*

Jahrbuch (1776), from 1830 till 1862 edited by Encke, and the *American Nautical Almanac* (1855).

Another kind of almanac, which has especially flourished in Germany and France, belongs rather to the class of publications known in Britain as *Annuaire* (q.v.). Such have been the *Almanach des Muses*, *des Dames*, *Populaire*, *Icarien*, *Napoléonien*, &c., the latter of which were specially devoted to the interests of political and religious parties.

The heavy stamp-duty of fifteenpence per copy, to which almanacs were long liable in the United Kingdom, was abolished in 1834, since which time the character, number, and circulation of this class of publications have strikingly advanced.

See CALENDAR, CLOG ALMANAC; a series of articles in *Notes and Queries* (1885); N. Champion's *Anciens Almanachs Illustrés* (1885); Whitworth's *Churchman's Almanac from 1201 to 2000* (1883); E. F. Bosanquet, *English Printed Almanacs and Prognostications* (1917).

Almandine. See GARNETS; also CARBUNCLE.

Almansa, a town of Spain, in the province of Albacete, 60 miles NW. of Alicante by rail. There is a ruined Moorish castle. An obelisk, about a mile distant, marks the spot where the French, under the Duke of Berwick, gained an important victory, on 25th April 1707, over an army of Spanish and English troops. Pop. 12,000.

Almansur ('the victorious'), the title assumed by Hashem II.'s general, Mohammed ben Abdallah (see KHALIF), and by Abu-Jafar, the second Abbassid Khalif (q.v.), who succeeded his brother in 754. Warfare, treachery, murder were his steps to the throne, and his whole rule was as cruel as its beginning. He especially persecuted the Christians in Syria and Egypt. In war against external foes he had but little success, Spain and Africa falling away from the eastern khalfate. He removed the seat of government from Kufa to Bagdad, which he built (764) at immense cost, raising the money by oppressive taxation. He introduced the pernicious custom of making his freed slaves, mostly foreigners, rulers of provinces. The best feature in his character was his patronage of learning. He caused the *Elements* of Euclid to be translated from the Syriac, and the famous fables of Bidpai from the Persian. Almansur died in 775 during a pilgrimage to Mecca, at the age of almost 70. See Noldeke's *Sketches from Eastern History* (1893).

Alma-Tad'ema, SIR LAWRENCE, R.A., painter, was born, a notary's son, at Dronryp, in the Netherlands, 8th January 1836. Originally destined for the medical profession, it was not until 1852 that he devoted himself to the study of art. In that year he entered the Academy of Antwerp, and subsequently studied under Baron Henry Leys. Obtaining letters of naturalisation as a British subject, he settled permanently in England in 1873. Early in life he had deeply studied Egyptian archaeology and Greco-Roman art, and the results of his oriental investigations are strongly apparent in his works, which are distinguished for their careful composition, their accuracy of design, and the beauty, sobriety, and finish of their colouring. The following works may be cited as perhaps best embodying his aesthetic principles and the general characteristics of his art: 'Entrance to a Roman Theatre' (1866); 'Tarquinius Superbus' (1867); 'A Roman Amateur' (1868); 'Pyrrhic Dance' (1869); 'The Vintage' (1870); 'A Roman Emperor' (1871); 'The Mummy' (1872); 'A Picture Gallery' (1874); 'After the Dance' (1876); 'The Seasons' (1877); 'A Sculptor's Model'—*Venus Esquilina* (1879); 'The Way to the Temple'—the artist's diploma work for the Royal Academy (1883); 'The Emperor Hadrian visiting a British Potter' (1884); 'An Apodyterium' (1886); and 'The Women of Amphis' (1887). In 1876 Alma-

Tadema exhibited at the Grosvenor Gallery three pictures, 'Architecture,' 'Sculpture,' and 'Painting.' 'The Conversion of Paula by St Jerome' (1898) was a masterpiece, and some of his portraits are noteworthy. Elected A.R.A. (1876), R.A. (1879), he was knighted in 1899, received the O.M. in 1905, and other orders. He died 25th June 1912. His second wife and one of his daughters are artists; another daughter has written novels and poems. There are books on him and his art by Ebers (1885), Miss Zimmern (1902), P. C. Standing (1905), and R. Dircks (1910).

Almeh, ALME, or ALMAI (Arabic *ālim*, 'wise,' 'learned'), a class of Egyptian singing girls in attendance at festivals, entertainments, or funerals. The Ghawazee, or dancing girls, are of a lower order. See NAUTCH GIRLS.

Almeida, one of the strongest fortified places in Portugal, is situated on the river Coa, on the Spanish frontier, in the province of Beira. In 1762 it was captured by the Spaniards, but soon restored. In 1810 it was defended against Marshal Massena by an English officer, until the explosion of a powder-magazine compelled him to capitulate. Pop. 3000.

Almeida, DON FRANCESCO DE, a famous Portuguese viceroy of the Indies, was the seventh son of the Count of Abrantes, and first distinguished himself in the wars with the Moors, but especially at the conquest of Granada in 1492. In 1505 his sovereign, Emanuel I., appointed him viceroy of the Portuguese possessions in the East Indies. On the voyage thither he deposed the king of Quiloa on the Mozambique coast, and, proceeding to Zanzibar, destroyed the town of Mombasa. In the Indian seas he asserted everywhere the superiority of the Portuguese flag, and strove to exclude the Egyptians and Venetians from all commerce with the East. At Cananor, Cochín, Ceylon, and Sumatra, he either built fortresses to protect the factories and commercial interests of his nation, or established new factories. With the king of Malacca, a commercial treaty was formed about the same time. His son, Lorenzo, carried on several expeditions as his father's lieutenant, visited Ceylon, discovered the Maldivé Islands and Madagascar, but soon after was surprised and killed in the port of Chaul, near Bombay. His father speedily took measures to revenge the death of his son upon the hated Mussulmans, when Afonso d'Albuquerque appeared on the scene (1507), having been sent out by the Portuguese government to supersede Almeida, whom it had begun to distrust on account of his brilliant successes. The latter refused to recognise Albuquerque as viceroy, and for some months kept him prisoner at Cochín. He now sailed along the coasts, burning and plundering various seaports, amongst others Goa, and at length utterly destroyed the Moslem fleet at Diu. From this fierce and avenging expedition he returned to Cochín, resigned his office into the hands of his successor, and set out on his homeward voyage. But he was slain in an obscure affray with savages on the site now occupied by Cape Town, 1st March 1510.

Almeria (Arabic *Al-Mariyat*, 'the conspicuous'), the chief town of a Spanish province on the Gulf of Almeria, on the Mediterranean, 120 miles E. of Malaga. It is surrounded by high walls extending from the sea to the hill, has a well-defended harbour, a cathedral, besides 26 churches and monasteries, and a grammar-school. In the time of the Moors, it was, next to Granada, the richest and most important town in the kingdom, with about 150,000 inhabitants, and flourished alike in arts, industry, and commerce, being the great port of traffic with Italy and the

East. At one time it was as terrible a nest of pirates as Algiers itself, under the Moorish chief Ibn Mayman, when even Granada, according to the proverb, was merely its 'farm.' Now, it has only a few trifling manufactures, although it still keeps up considerable trade in grapes, esparto, lead, iron-ore, sulphur, and wine. Its grapes are peculiarly suitable for exportation. The much-needed railway from Linares was not completed till 1894. Pop. 40,000.—The province of Almería consists of the eastern portion of the ancient kingdom of Granada, and has an area of 3400 sq. m. The soil is fertile, but the province is not very prosperous. There are rich mines in the sierras, yielding copper, iron, mercury, silver, and lead. Pop. 350,000.

Almodóvar del Campo, a town of New Castile, Spain, 22 miles SW. of Ciudad Real. The inhabitants are chiefly employed in agriculture and silver-mining. Pop. 12,500.

Almohades, the name of a Moslem dynasty that ruled in Africa and Spain during the 12th and 13th centuries. The word is Arabic, signifying 'worshippers of the one true God,' and was assumed as a term of distinction. This sect, which at first was religious rather than political, was founded among the Atlas Mountains by Ibn Tomrul Abdallah, and in 1146, under the leadership of Abd-ul-Mumen, put an end by the conquest of Morocco to the empire of the Almoravides in Africa, and next extended its career of conquest to Spain. Under Jakub Almansor they won in 1195, at Alarcos, a great victory over the Castilians. In 1210 Mohammed, the successor of Jakub, came with a great army to Spain, but was overthrown in 1212 by the united kings of Castile, Aragon, and Navarre, in the famous battle of Navas de Tolosa, in which it is said that 100,000 Moors were left upon the field. This great defeat was the beginning of the downfall of Moorish power in Spain; its most immediate result was the disappearance of the Almohades from the peninsula. The empire of the Almohades in Africa was brought to an end in 1269, through revolts of the nomadic tribes. See ALMORAVIDES; and Dozy's edition of the History of Abd-ul-Wahid (1847, 2d ed. 1881).

Almond (*Amygdalus*), a genus of the natural order Rosaceæ (q.v.), sub-order Amygdalæ or Drupacæ, consisting of trees or shrubs, distinguished by the coarsely furrowed and wrinkled shell (*endocarp* or *putamen*) of the drupe, and by

The Almond :
a, flower; b, fruit.

the young leaves being conduplicate, or having their sides folded together. This sub-order (see APRICOT, CHERRY, and PLUM) also comprises the other two genera of Peach (q.v.) and Prune (q.v.), in which the drupe has a fleshy covering (*sarcocarp*), whereas in the species to which the

name almond is commonly given, this part is a dry fibrous husk, which shrivels as the fruit ripens, and finally opens of its own accord. The almond-tree (*Amygdalus communis*) is very similar to the peach-tree, and is about 20-30 feet high, a native of the East and of Africa, but has now become completely wild in the whole south of Europe. Even in the more northern parts of Germany and of Britain it is planted for the sake of its beautiful flowers, which are produced in great abundance, and resemble those of the peach in form and often in colour, although generally paler and sometimes white. The blossoms appear before the leaves, and are very ornamental in shrubberies in March and April. The wood of the almond-tree is hard, and of a reddish colour, and is used by cabinet-makers. But it is chiefly valued on account of the kernel of its fruit, which forms an important article of commerce. The almond-tree is often referred to in the Old Testament, and the word translated *hazel* is supposed to be another name for the almond. The tree flowers in Palestine in January. The rod of Aaron, mentioned in Numbers xvii., was taken from an almond-tree, and it is yet customary with the Jews to carry rods of almond-blossom to the synagogue on festival days. It seems to have been very early introduced into England, and is named in the *Durham Glossary* (11th century) the 'Easterne Nutte-Beam.' Its great beauty has made it a favourite with every one wherever it can be successfully grown. Gerard, in Shakespeare's days, says the trees were 'in our London gardens in great plenty;' but Spenser had sung of its beauty before that time. It is only in the most favoured situations in the south of England that it ever produces good fruit.—Almonds are either sweet or bitter. The bitter appear to be the original kind, and the sweet to be an accidental variety, perpetuated and improved by cultivation. Sweet almonds contain a large quantity of a very bland, fixed oil, emulsin, gum, and mucilage sugar, are of a very agreeable taste, and very nutritious, and are used in the dessert, in confectionery, and medicinally in an emulsion, which forms a pleasant, cooling, diluent drink. Bitter almonds contain the same substances, and, in addition, a substance called *Amygdalin* (q.v.), from which is obtained a peculiar volatile oil. (For the almond *oils*, see the following articles.)—The muddy water of the Nile is clarified by rubbing bitter almonds on the sides of the water-vessels, in the same way in which the nuts of the *Strychnos potatorum* (see CLEARING NUT) are used in India. The principal varieties of almond in cultivation are the *sweet* almond (*A. dulcis*), with thick hard shell; the *brittle-shelled*, with a very thin, almost leathery brittle shell and sweet kernels; the *bitter* (*A. amara*), with thick hard shell (sometimes also with a brittle shell) and bitter kernels; the *large-fruited*, with large flowers of a whitish rose-colour, and very large, sweet fruit; the *small-fruited*, with very small sweet fruit; and the *peach* almond, with a slightly succulent blackish *sarcocarp* (see above), yellow shell, and sweet kernels. In commerce, the long almonds of Malaga, known as Jordan almonds, and the broad almonds of Valencia, are most valued. Large quantities of almonds are annually imported into Britain and America from France, Spain, Italy, and the Levant; and California produces large quantities. Bitter almonds are brought to Britain chiefly from Mogador.—The DWARF ALMOND (*A. nana*) is very similar to the common almond, except that it is a low shrub, seldom more than two or three feet in height. Its fruit is also similar, but much smaller. It is common in the plains of the south of Russia, and is frequently planted as an ornamental shrub in Britain, flowering freely in March and April, but not producing fruit.

Almondbury, a SE. part of Huddersfield (q.v.).

Almonds, FIXED OIL OF. When almonds are subjected to pressure, a fixed greasy oil exudes. Either bitter or sweet almonds may be employed; but the former are generally used, as they are cheaper than sweet almonds, and the cake which is left is valuable in the preparation of the *essential oil*. 1 cwt. of the almonds generally yields 48 to 52 lb. of the fixed oil. When first obtained it possesses a turbid or milky appearance; but when it is allowed to stand at rest the impurities settle, and a clear, light, yellow oil remains above. It has the specific gravity of .920, and does not solidify till it is cooled to between +14° and -5° F. (-10° and -20° C.). When fresh it has a mild nutty taste, but soon becomes rancid by exposure to the air; it is not, however, one of the drying oils. It consists almost wholly of *triolein*, a compound of glycerine with oleic acid. The fixed oil of almonds possesses a mild laxative property, and is beneficial also in allaying troublesome coughs, and applied externally is used in the form of cold creams for chapped hands, &c.

Almonds, VOLATILE OIL or ESSENTIAL OIL OF. The cake which is left after the expression of the fixed oil from bitter almonds contains, among other matters, a portion of two substances called respectively amygdalin and emulsin. When the cake is bruised and made into a paste with water, the emulsin acts as a ferment upon the amygdalin, splitting it up into the volatile oil of almonds, hydrocyanic (prussic) acid, grape-sugar, and water. The oil is not originally present in the bitter almonds; in fact, the latter do not contain a trace of the oil ready formed, so that the oil is purely the product of the fermentation of amygdalin, 100 parts of which yield 47 of crude oil. This action takes place very rapidly, and is complete within 24 hours. The crude oil thus obtained decomposes gradually, the prussic acid being set free, and on this account it is very poisonous, many fatal cases having occurred from its wilful, accidental, or careless use. The crude oil is purified and freed from prussic acid by means of sulphate of iron and lime. On redistillation it has a specific gravity of 1.049, as compared with 1.064 in the crude state, and must be carefully freed from water by being shaken with fused chloride of calcium. The yield of crude essential oil is very variable, ranging from 4 to 9½ lb. from 1000 lb. of bitter almonds, and this again is reduced by about 10 per cent. during its purification from prussic acid. The volatile oil (C_6H_5COH) is the aldehyde of benzoic acid (C_6H_5COOH), into which substance it rapidly changes when exposed to the air in a moist state. It has an agreeable odour, an acrid, bitter taste, and burns with a smoky white flame. It is soluble to the extent of 1 part in 30 parts of water, and is very soluble in alcohol and ether. Heated to 356° F. (180° C.), it boils, and distils over unaltered. At the present time 'benzaldehyde' or synthetic oil of bitter almonds is largely used, and has an advantage in its freedom from prussic acid. The benzaldehyde is made from toluene (C_6H_5). In medicine the crude oil used to be employed in place of prussic acid, but its variability in strength has led to its disuse for this purpose. The cook and confectioner employ the oil for flavouring custards, &c., and it forms the basis of several flavouring essences, as ratafia. For these purposes none but oil freed from prussic acid must be used. Synthetic oil is used for perfuming soaps. Much of the bitter almond oil of commerce is made from peach and apricot kernels.

Almoner, that functionary of a religious house who had the dispensing of the money and other things set apart for alms, which must, by canon law, amount to at least a tenth of the revenues of

the establishment. Afterwards, those ecclesiastics also received this name who were appointed by princes or bishops to the same office in their households. The Grand Almoner of France was one of the principal officers of the court and of the kingdom, usually a cardinal. Queens, princes, and princesses had also their almoners, and bishops were usually appointed to this office. In England, the office of *Hereditary Grand Almoner* is now a sinecure, his only duty being to distribute the coronation medals among the assembled spectators. The *Lord High Almoner*, who is usually a bishop, distributes twice a year the royal bounty, which consists in giving a silver penny apiece to as many poor persons as the sovereign is years of age.

Almo'ra, the principal town of the British district of Kumaun (q.v.), United Provinces of India, 87 miles north from Bareilly, on the crest of a ridge of the Himalayas, 5337 feet above the sea. It was an important centre in the Gurkha war of 1815. Pop. 8000.

Almoravides (Arabic *al murabitun*, from the *rabita* cell or hermitage where they first assembled), name of an Arab dynasty that ruled in Africa and Spain in the 11th and 12th centuries A.D. The sect took its rise about the middle of the 11th century among the Arab and Berber tribes which dwelt on the slopes of the Atlas range facing the Atlantic, and was founded by a Moslem teacher called Abdallah-ben-Yasin. The new proselytes soon exhibited the fruits of his teaching by descending from their hills, under the leadership of a chief named Abubekr, and conquering the kingdom of Fez. The adjoining kingdom of Morocco shared the same fate; and the victorious fanatics, under the famous Yussuf-ben-Tasfin, the cousin of Abubekr, next crossed the Strait of Gibraltar, and subdued Spain to the Tagus on one side, and to the Ebro on the other. During the reign of Ali, the son of Yussuf, the Almoravides fell before the sect of the Almohades (q.v.), which first expelled them from Africa, and next subdued their power in Spain. It was the Almoravide princes who introduced the *Maravedi* (q.v.) into Spain, and in that and the word *Marabouts* (q.v.) their name is still preserved. See Dozy, *Histoire des Musulmans d'Espagne* (4 vols. 1861).

Almqvist, KARL JONAS LUDVIG, a Swedish author, was born at Stockholm in 1793, and died in 1866 at Bremen, after a singular career, in which, after taking priest's orders he was charged with heresy. Later, though apparently innocent, he had to flee as a suspected forger and would-be assassin to America, where, under an assumed name, he became Abraham Lincoln's secretary. His works, a selection from which fills 4 vols. (1875), included his masterpiece, *Tornrosens Bok*, and other poems, besides novels, plays, and historical, critical, and philosophical writings.

Almshouse. An almshouse is a house or set of houses in which accommodation is provided for persons disabled by age and poverty. Great abuses formerly prevailed in some of these institutions. In some, persons of good position were received, and the intrusion of a poor man or woman was resented by the inmates. In others (as, for instance, in the Hospital of St Cross at Winchester), the master appropriated the whole of a great revenue, except what was required to carry out the letter of the founder's will. Abuses of this kind were checked by the appointment of a permanent Charity Commission in 1853. In Scotland, almshouses generally bear the name of Hospital (q.v.).

Almucantar, a small circle of the heavens parallel to the horizon; also an instrument invented by Chandler, whereby the telescope can be used to observe a star passing a given altitude.

Almug Tree, or **ALGUM TREE**. This name, occurring in the Old Testament, was formerly supposed to denote a species of acacia, or a coniferous tree like the cypress; but it is now thought more probable that it was one of the kinds of Sandalwood (q.v.), the *Santalum album*, a native of India.

Almuñecar, a seaport town of Andalusia, Spain, 33 miles S. of Granada, with trade in cotton, sugar, and fruit; pop. 8000.

Alnus. See **ALDER**.

Alnwick ('town on the Alne'), the county town of Northumberland, 38½ miles N. by W. of Newcastle by rail. It is a well-built place, with a large central market-place, a spacious town-hall, and a corn-exchange of 1862. Alnwick was at an early period a fortified town, and one of its four gates remains, with fragments of the walls. At the north entrance of the town stands Alnwick Castle, the seat originally of the De Vescis, and since 1310 of the House of Northumberland (see PERCY). It has been sumptuously restored since 1854 in the Italian palazzo style, and is one of the most magnificent baronial structures in England. During the middle ages, it was a bulwark against the invasions of the Scots, and it was thrice besieged—by Malcolm Canmore, who here met his death; by David I., who captured it; and by William the Lion, who here was taken prisoner. Alnwick ceased in 1886 to enjoy certain prescriptive municipal usages it formerly possessed. Pop. 7000. See the great *History of Northumberland* by Bateson, Hodgson, and others (1893-1910).

Aloe (*Aloe*), a genus of plants of considerable medicinal importance, belonging to the natural order Liliaceæ (q.v.), sub-order Aloineæ. There are about 100 species, of which most are indigenous to South Africa. The species all have stems, but vary in height from a few inches to 30 feet. They have permanent succulent leaves. The negroes of the west coast of Africa make cords and nets of the fibres of their leaves, and stockings are woven from the fibres of a species found in Jamaica. But aloes are chiefly valuable for their medicinal properties. The well-known drug called Aloes (see below) is the inspissated juice of the leaves of several almost tree-like species, and particularly of *Aloe socotrina*, *perryi*, *purpurascens*, *spicata*, *fruticosa*, and *indica*.

Aloe vulgaris is found in the East Indies, in Italy, and in some of the islands of the Mediterranean, being the only species which can be reckoned European, although it also is probably an introduced plant. The *American Aloe* is a totally different plant (see AGAVÉ). The aloes of the Bible was the wood of a tree (see next article).—The juice of aloes was anciently used in embalming,

colour is obtained from the leaves of the Socotrine aloes, which also affords a fine transparent colour for miniature painting.

ALOES is a drug of great antiquity, for we find it mentioned by Dioscorides (50 A.D.). Till modern times, the source of the drug was the island of Socotra, but at present it is imported from various parts of the world. The chief varieties are distinguished by colour, smell, and fracture, and in the London market are: *Socotrine aloes*—derived from the *Aloe perryi*, not from the *Aloe socotrina*, which was till recently believed to be the source of the drug; *Barbadoes aloes*; *Cape aloes*; and *Natal aloes*.

These various forms of the drug are derived from several species of aloes, but they all agree in possessing a bitter taste, and having powerful purgative properties. Active principles, similar in nature but differing in composition, are found in the three chief varieties. These are Socaloin, $C_{12}H_{16}O_7$, found in Socotrine aloes; Nataloin, $C_{16}H_{18}O_7$, found in Natal aloes; Barbaloin, $C_{17}H_{20}O_7$, found in Barbadoes aloes.

When employed in small doses as extract, tincture, pills, or otherwise, aloes exerts a tonic, and in larger doses, a cathartic action.

Aloes Wood (sometimes called also Eagle Wood, Calambac, Paradise Wood, or Agallochum) is the heart-wood of *Aquilaria ovata* and *A. Agallochum*, trees of the order Thymelæaceæ, natives of the tropical parts of Asia, and supposed to be the aloes or lign-aloes of the Bible. They are large spreading trees. Aloes wood contains a dark-coloured, fragrant, resinous substance, and is much prized in the East as a medicine, and for the pleasant odour which it diffuses in burning. The resinous substance is found only in the inner part of the trunk and branches; the younger wood is white, and almost scentless; hence the pure aloes wood is sometimes obtained by burying the stems, when the sap-wood decays away, leaving the resinous core intact. A similar substance, still more esteemed, is obtained in the south-eastern parts of Asia and the adjacent islands, from the central part of the trunk of *Aloexylon Agallochum*, of the natural order Leguminosæ, sub-order Cæsalpineæ. This tree is found in Cochinchina and the Moluccas, where a character of sacredness is attached to it. Its fragrant wood is not only much prized in the East as a perfume, but many medicinal virtues are ascribed to it. The ancients ascribed to it similar virtues, and so valued it for these and its fragrance, that Herodotus says it once sold for more than its weight in gold. As it admits of a high polish, and exhibits a beautiful graining, precious gems were set in it; and it was cut into fantastic forms and worn in head-dresses, &c. It was early used to perfume apartments, and Napoleon I. used it as a perfume in his palaces. The fragrance continues undiminished for years. *Lign Aloes* is a corruption of *Lignum Aloes* (literally 'wood of aloes,' where *aloēs* is trisyllabic, being the genitive case of *Gr. aloē*).

The name Aloe Wood is applied to *Cordia Sebestana*, a tree of the family Boraginaceæ, found in Florida, the West Indies, and northern South America. It has an edible fruit, which, like that of *C. Myxa* in the East, has been used medicinally.

Aloexylon. See **ALOES WOOD**.

Alögians, or **ALOGI**, a sect of Christians that arose in Asia Minor about 170 A.D., so called from their rejection of the doctrine that Christ was the divine Logos, and of the fourth gospel, which, with the Apocalypse, they ascribed to Cerinthus (q.v.) the Gnostic. The same name was given later to the Socinians.

Aloidæ, **ALOIDÆ**, or **ALOADÆ**, in Greek myth-

Aloe socotrina

ing, to preserve dead bodies from putrefaction. In the East Indies, it is employed as a varnish to prevent the attacks of insects. A beautiful violet

ology, were two giants, Otus and Ephialtes, sons actually of Poseidon, reputedly of Aloeus, Poseidon's son. Growing every year an ell in breadth and a fathom in height, they were able at the age of nine to make war upon the Olympian gods, and proceeded to pile the mountains, Pelion upon Ossa, Ossa upon Olympus, but were killed by Apollo's arrows. According to another account they became suitors for Hera and Artemis. In the island of Naxos, Artemis ran between them in the form of a stag, at which they shot, and so killed each other. One of their feats was to imprison Ares for thirteen months.

Alora, a town of Spain, in the province of Málaga, 23 miles NW. of Málaga by rail. There are ruins of an ancient castle. Pop. 11,000.

Alosa. See CLUPEIDÆ and SHAD.

Alost. See AALST.

Aloysia. See VERBENA.

Aloysius, St., the name given to Luigi Gonzaga, who was born in the castle of Castiglione, near Brescia, 9th March 1568, and was educated at Florence, Mantua, and Rome. Renouncing his marquise of Castiglione in favour of his brother, he entered the Society of Jesus in 1585. At Rome during a visitation of the plague he gave himself up with wonderful self-devotion to the care of the sick, and, stricken by the malady, died 21st June 1591. He was beatified in 1621, and canonised in 1726. See the *Life of St Aloysius Gonzaga*, edited by E. H. Thompson (1867); the Italian Life by Cepari (trans. by Goldie, 1891); and Aubrey de Vere's *Essays* (1838).

Alp, in Switzerland, means not a mountain, but a pasture situated high on a mountain, used only in summer. Many alps are owned by communities (*Alpgemeinden*).

Alpaca (*Lama pacos*), a domesticated race, belonging to the Camel family, established many ages ago in Peru and Bolivia, and bred for the sake of its fine silk-like wool. The alpaca is smaller than its near relative, the llama (*Lama glama*), another domesticated race, and has a relatively longer neck. The two races are mutually fertile. It is usually held that both llama and

Alpaca.

alpaca have been derived from the wild guanaco (*Lama huanachus*). According to another view, the alpaca is derived from the wild vicuña (*Lama vicugna*). It may also be that the alpaca, while derived from the guanaco, has in it a strain of vicuña blood.

Alpacas live in flocks at great elevations on the Andes, and are shorn every year. There are two kinds of wool, the inner short and soft, the outer very long and strong. It varies much in colour. From time immemorial the wool has been used in South America for blankets and cloaks (*ponchos*), and enormous quantities are now imported into

Britain. The credit of introducing and raising to its present magnitude the alpaca wool-manufacture in Britain, which has still its chief seat at Saltaire, is due to Sir Titus Salt. Attempts to establish the alpaca in Europe, the United States, and Australia have not met with much success. Alpaca wool is straighter than that of the sheep, very strong in proportion to its thickness, and breaks little in combing. The fibre is small, and it is very soft, pliable, and elastic.—The flesh of the animal is said to be very wholesome and pleasant.

Alp-Arslan, a Persian sultan, the second of the Seljuk dynasty, born in Turkestan in 1029. In 1059 he ascended the throne of Khorassan, and in 1063, on the death of his uncle, became monarch of all Persia. He embraced Islam, taking the name of Mohammed, and by his bravery obtained the surname of Alp-Arslan ('Brave Lion'). He took and plundered the city of Cæsarea, in Cappadocia. In 1064 he invaded Armenia and Georgia, at that time Christian kingdoms, and added them to his dominions. In 1068 he marched against the Greeks of the Eastern empire, who, under the Emperor Romanus Diogenes, had thrice driven back the Turks beyond the Euphrates. In 1071 a bloody battle was fought, the Seljuks gaining a decisive victory. The Greek emperor was taken prisoner, and only obtained his liberty by an enormous ransom and a large annual tribute. Marching to the conquest of Turkestan in 1072, the sultan perished by the dagger of a captive enemy.

Alpena, a port and city at the mouth of Thunder Bay River, in Michigan, with foundries and saw-mills; pop. 11,000.

Alpenhorn. See KUH-HORN.

Alpes is the name of three departments in France. That of BASSES-ALPES occupies the NE. part of Provence, and is the most sparsely populated in all France. It is for the most part mountainous, consisting of spurs or offshoots from the Maritime Alps, which run in numerous chains towards the Rhone. In the north the climate is cold, the soil poor, and the cultivation bad; in the south the climate is much better—almonds, apricots, peaches, and various other choice fruits are grown. The wines are excellent. The mines produce lead, green marble, &c. At Digne and Gréoulx there are mineral springs. The department is watered by the Durance. The area of the department is 2697 sq. m.; pop. (1901) 112,763; (1921) 91,882. The chief town is Digne.

The HAUTES-ALPES, lying north of the Basses-Alpes, and forming a part of the old province of Dauphiné, is traversed by the chief range of the Cottian Alps, which here rise, in Mount Pelvoux, to the height of 14,000 feet. The scenery, especially along the course of the impetuous Durance, is singularly picturesque. The *Hautes-Alpes* is, after Savoy, the highest department in France; the fierce north wind and the perpetual snow on the lofty peaks make the climate severe and the winter long, so that the barren soil will yield little else than potatoes, a little rye, oats, and barley, although thick forests clothe the mountain-sides. Area, 2178 sq. m.; pop. (1901) 106,857; (1921) 89,275. The mines produce lead, copper, iron, and anthracite. Every autumn some four or five thousand people leave the colder heights to seek employment during the winter months in the lower department. Chief town, Gap.

ALPES MARITIMES, a department in the extreme SE., on the shores of the Mediterranean and confines of Italy, was formed in 1860. It is made up of the ancient county of Nice, which was ceded in that year to France, and of the arrondissement of Grasse. The chain of the *Alpes Maritimes* forms the northern boundary of the department, and from

it numerous spurs run seaward, among which are lovely and fertile valleys. The climate is delightfully mild on and near the coast, which forms part of the Riviera (q.v.), but the higher mountains reach to altitudes where winter always reigns. The vine and olive are much cultivated in the more favoured localities; tobacco, oranges, lemons, and figs are produced; and much land is devoted to the cultivation of herbs and flowers for the preparation of essences and perfumes. Grasse is particularly famous for the manufacture of perfumery. The silkworm is reared, and honey is largely produced and exported. There are some mineral springs. The tunny, anchovy, and sardine fisheries are important. The capital is Nice (q.v.), and the other principal towns are Antibes, Villefranche, Cannes, Grasse, and Menton or Mentone. The area is 1443 sq. m.; pop. (1901) 320,822; (1921) 357,759.

Alphabet, so called from *alpha* and *beta*, the first two Greek letters, is the name given to a set of graphic signs, called letters, denoting elementary sounds, by the combination of which words can be visibly represented. These signs reached their final form after passing through stages which, broadly treated, are as follows:

A. The **MNEMONIC**, or memory-aiding, when some tangible object is used as a message or record. It borders on the symbolic; in fact, it anticipates that stage. It is represented (1) by the ancient Peruvian 'quipus' or knotted cords, the single or double or multiple knots denoting given numbers, while the colours of the cords represented different meanings; and also (2) by the Red Indian wampums or bead and shell ornamented belts, the devices on which recorded events or titles to land. A familiar mnemonic is tying a knot in a handkerchief.

B. The **PICTORIAL**, which tells its own story, as in the Red Indian record of an expedition across Lake Superior, shown in the illustration. It was led by 'Wolf,' a noted Indian chief. The crew of each canoe is denoted by upright strokes, 'Wolf's' chiefly, 'Kingfisher,' being in the first canoe. The arch with three circles (three suns under heaven)

Fig. 1.—Indian Expedition Record.
(From Schoolcraft's *Indian Tribes*)

shows that the voyage took three days. The tortoise (a frequent symbol of land in North American picture-writing) may indicate the arrival of the expedition.

In his *Formation of the Alphabet* (1913) Professor Flinders Petrie formulates a theory that the alphabet is traceable to the signary, and not to the pictograph, signs being older than pictures, because the necessity for them arose through trade intercourse and as direction-marks among tribes. But he admits 'the need of further research,' and probably in this, as in other inquiries into origins, it will be found that more than one set of causes have operated to secure a like result.

C. The **IDEOGRAPHIC**, in which the picture becomes representative—i.e. is converted into a symbol, as an arrow to denote an enemy; a calumet, peace; a bee, industry; an ostrich-feather,

justice, because these feathers were said to be of equal length; a brandished whip, power; two arms, one holding a shield and the other a javelin, a battle.

Six probably independent systems of ideographic writing are known: (1) The Cuneiform, which arose in the valley of the Euphrates, and developed into the Achaemenian syllabaries. (2) The Cretan, which was the probable source of the Cypriote syllabary, if not also the Caian and Lycian ones. (3) The Hittite system, perhaps connected with the Cretan. (4) The Chinese, out of which the Japanese syllabaries have arisen. (5) The Egyptian hieroglyphics. (6) The Mexican picture-writing.

The Cuneiform, the Chinese, and the Egyptian scripts will be treated of under their proper headings. See **CUNEIFORM**, **CHINA** (*Language, Writing, and Literature*), and **HEROGLYPHICS**.

D. The **PHONETIC**, in which the picture becomes a phonogram, or sound-representing sign. This may be (1) *verbal*—i.e. a sound-sign for a whole word; (2) *syllabic*—i.e. a sound-sign for syllables; or (3) *alphabetic*, a sound-sign for each vowel or consonant.

To recapitulate stages B, C, and D:—In stage B the sign as eye-picture suggests the thing; in stage C the sign as eye-picture suggests the name; and in stage D the sign as ear-picture suggests the sound, and it is in the passage from C to D, whereby constant signs are chosen to stand for constant sounds, that the intellectual progress of the human race was assured, because only thereby was the preservation of all that is of abiding value made possible. In brief, the origin of the alphabet was due to the ingenious discovery that, all the words which men utter being expressed by a few sounds, symbols of these could be selected accordingly; hence the twenty-six letters of our alphabet make up the half-million words contained in the *Oxford English Dictionary*. A perfect alphabet is not possible, because sounds, especially those of vowels, are not constant in any language, and in the case of languages which are no longer spoken, the pronunciation is matter for question not likely to be settled. See **ENGLISH LANGUAGE** (*Sounds*), **PHONETICS**, **SPELLING**.

The ultimate source of the original characters whence our own and cognate alphabets are derived remains uncertain, but their immediate descent from the Phœnician, which was in use about the 10th century B.C., is generally accepted. What remains question for possible settlement is the script whence the Phœnicians, a Semitic people, borrowed or adapted theirs. The transition to a pure alphabetic writing was long assigned to them as borrowers of the art of writing

from the Egyptians, whose hieroglyphic picture-writing may be traced back, by means of inscriptions, for more than six thousand years, to the time of the second Egyptian dynasty, when it already appears in great perfection, arguing a long period of antecedent development. It consisted of pictorial ideograms, which, at some unknown epoch, must have given birth to verbal phonograms, some of which came to be used as syllabic signs. Of the 400 Egyptian phonograms, about 45 attained an alphabetic character; that is, they either denoted vowels, or could be associated with more than one vowel-sound. But though the Egyptian hieroglyphic writing contained the germs of an alphabet, it was not truly alphabetic. It remained to the last partly ideographic, partly phonetic. Alphabetic and syllabic signs are conjoined with verbal phonograms, and these are explained by means of pictorial

ideograms. Traditions were current from Plato to Tacitus that 'the Phœnicians did not claim to be themselves the inventors of the art of writing, but admitted that it was obtained by them from Egypt'; while in modern times not a few attempts had been vainly made to derive the several Phœnician letters from suitable hieroglyphic pictures. The supreme merit of the Phœnicians, on this theory, was that they rejected the unnecessary portions of the complicated Egyptian system, the ideograms, the verbal phonograms, and the syllabic signs, and selected from the 45 variant symbols of elementary sounds a single sign for each of the 22 consonants which are found in Semitic speech. To ourselves the notion of alphabetic writing seems extremely simple, but in reality the passage from ideographic picture-writing to a pure alphabet is one of the greatest triumphs of the human mind. None of the other systems of picture-writing—Chinese, Cuneiform, or Hittite—advanced beyond a more or less perfect stage of syllabism.

To a French scholar, Vicomte Emmanuel de Rougé, is due the most elaborate form of the Egyptian theory of the alphabet. In a paper read before the Académie des Inscriptions in 1859 (and rescued from oblivion in 1874) De Rougé worked out a scheme on the theory that the prototypes of the Phœnician letters must be sought, not in the hieroglyphics of the monuments, but in certain cursive 'hieratic' or priestly characters, so extremely ancient that they had already fallen into disuse at the time of the Hebrew exodus. This form of hieratic writing is known to us almost exclusively from a single manuscript, the *Precepts of Ptah-Hotep*, commonly known, after its donor, M. Prisse d'Avennes, as the Papyrus Prisse, found in a tomb belonging to the eleventh dynasty (see illustration at WRITING). In the Papyrus Prisse the characters bear hardly more resemblance to the hieroglyphs from which they were derived than they do to the earliest known forms of the Phœnician letters; but De Rougé insisted that the chief difference was due to the fact that the Egyptian was a cursive script, used for writing on papyrus, whereas the Phœnician letters were lapidary characters, adapted for engraving on stone. Hence straight lines are substituted for flowing curves, and sharp angles for rounded forms. De Rougé attempted to show that twenty-one of the most suitable of the Egyptian characters were selected from the rest, and taken over, only one new letter, 'ayin, the source of our *o*, having been added by the Phœnicians. His identifications were, for the most part, long accepted by those scholars who were best entitled to speak with authority. One difference was explained by supposing that the Egyptian characters were renamed, on the acrologic or initial principle, by means of words significant in Semitic speech, each of the new names being chosen from a resemblance, more or less close, between the form of the letter and some familiar object whose name began with the letter in question. Thus the first letter was no longer called *ahom*, the eagle, but *aleph*, the ox; and the thirteenth letter, instead of being *mulak*, the owl, became *mem*, the waters. In like manner, in our nursery picture-alphabets, the child is told that O was an orange, S was a swan, and B was a butterfly. A similar acrologic renaming of the letters by significant terms has repeatedly taken place on the transference of alphabets. We have instances in the case of the Runic, the Russian, and the Old Irish alphabets.

On the Semitic side there are the Egyptian words

which are given in Semitic form in the Old Testament, and the Semitic names of Syrian towns which are found in the Egyptian annals of conquests under the new empire, through which the sounds severally represented by the Semitic and hieratic characters are arrived at. The chief source of epigraphic evidence is an inscription on the sarcophagus of Eshmunazar, king of Sidon, found in a rock-tomb near the site of ancient Sidon. It

Fig. 2.—Inscription on the Eshmunazar Sarcophagus.

dates from the 5th century B.C., or about two thousand years later than the Papyrus Prisse, and therefore represents a later form of the Phœnician alphabet. It is preserved in the Louvre. Eshmunazar, whose mask and mummy are sculptured on it, speaking in the first person, boasts of the temples which he and his mother, the priestess of Ashtaroth, had built to that and other deities. He beseeches their favour, and prays that Dora, Joppa, and Sharon may remain parts of his kingdom. He laments that he is cut off before his time, and implores that no man may open his 'funeral couch,' neither seeking for treasure therein, neither putting it in another tomb.

Symmetrical as M. de Rougé's theory appears, and falling into line with accepted theories of the sources of Western civilisation, it held the field until recent years. But it must be classed with hypotheses lending themselves to the staining of facts in their support, and citing superficial resemblances as proof of relation. In his article on 'Hieroglyphs' in the *Encyclopædia Britannica*, Mr Reginald Poole remarks that 'the hieratic forms vary, like all cursive forms of writing, with the hand of the scribe. Consequently the writers who desire to establish their identity with Phœnician can scarcely avoid straining the evidence.' Moreover, the long lapse of time between the materials for comparison invites caution. The Papyrus Prisse is, at least, two thousand years older than the Eshmunazar inscription, and on the evidence supplied by these two hangs the validity of M. de Rougé's theory. But within recent years light upon another possible source of the alphabet has come from hitherto unknown materials.

Investigations in Crete since 1893, especially those of Sir Arthur Evans in the palace at Knossos, have disclosed a system of pictographic-writing (in the 'early Minoan period') which develops into an abridged hieroglyphic form ('middle Minoan'), as does that again into two forms of lineary script ('late Minoan'), making out a fair case for a Cretan origin for the Phœnician alphabet. For instance, a Cretan letter identical with *aleph* can be traced to a Cretan hieroglyph representing the head of an ox.

The results of the excavations in Crete are the fact of an indigenous culture and of an active intercourse between that island and Greece, Egypt, Syria, and

other countries many centuries before the Phœnicians launched their craft upon the Mediterranean and trafficked with Cyprus or Crete. And although the Cretan pictographs and linear symbols await decipherment by the aid of a bilingual inscription, such as that on the Rosetta stone, which gave the key to the Egyptian hieroglyphs, sufficient evidence is adduced by Sir Arthur Evans to warrant the inference that the Cretan signs were taken over by the 'Cherethites and Pelethites,' or Philistines, who settled on the coast of Syria, passing on these signs to their neighbours and possible kinsfolk, the Phœnicians. The data for that inference are given in Sir Arthur's paper on 'Primitive Pictographs and a Pre-Phœnician Script from Crete and the Peloponnese' in the *Journal of Hellenic Studies*, vol. xiv. pt. 2 (1897), and, more elaborately, in his *Scripta Minora*, vol. i. pp. 77 ff. (1909).

The Phœnician, the mother of alphabets, having arisen out of some form of picture-writing, Cretan, Egyptian, or other, it is not difficult to explain here the affiliation of a few of the more important daughter alphabets, such as the Hebrew, the Syriac, the Arabic, the Indian, the Greek, and last, but not least, the Roman alphabet which we ourselves employ. The 22 letters of the Phœnician alphabet were the fruitful germs from which the letters of all other alphabets have been developed. In the Semitic alphabets the number of letters has remained constant, though the outlines have been so degraded that in some alphabets, such as the Arabic, many letters are almost formless; while in Aryan alphabets new letters have been abundantly developed by differentiation, a process well exemplified in our own alphabet, in which J has been evolved out of I, and G from C, while F, Y, V, U, and W are all descended from the Phœnician *vau*.

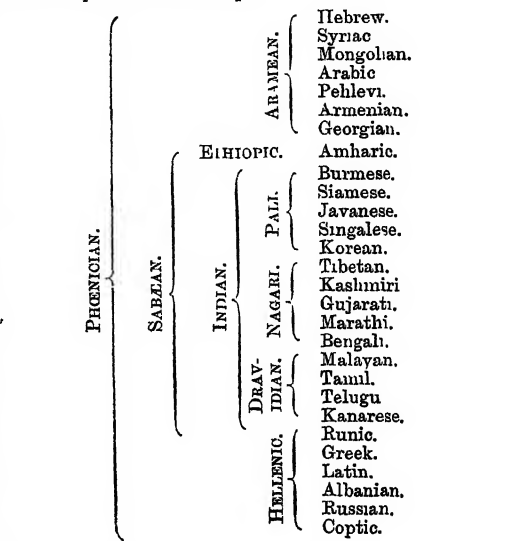

The chief difference between Semitic and Aryan alphabets is due to a fundamental distinction between the Semitic and Aryan languages. In the Semitic scripts there are no true vowels, these being denoted only by diacritical points; whereas in the Aryan alphabets vowel-signs have been developed out of the characters representing the Semitic breaths and semi-consonants. The Semitic alphabets have also retained the original direction of the writing, from right to left; whereas in the non-Semitic scripts the more convenient direction, from left to right, has been adopted.

Many attempts have been made to explain the order of the letters in the alphabet. It would take too much space to discuss fully this obscure question, but it is generally recognised that the order of the Hebrew letters exhibits traces of a primitive phonological classification. Omitting certain letters which do not readily fall into the scheme, and whose places may have been assigned at a later time, the original arrangement seems to have been in four classes, containing respectively letters representing the soft, the continuous, the liquid, and the hard sounds, the first letter in each class standing for a faucal breath, the second a labial, the third a palatal, the fourth a dental, and the fifth probably a sibilant. The survivals of this arrangement are exhibited in the following table. The places assigned to the sibilants are hypothetical.

	Faucal Breath.	Labials.	Palatals.	Dentals.	Sibilants.
Soft.....	ʾ	b	g (c)	d	s
Continuous.....	e	v (f)	ch (h)	th (t)	sh
Liquid.....	z	m	l	n	s
Hard.....	o	p	q	t	ts

We have now to describe the chief families of alphabets to which the mother-alphabet of Phœnicia gave birth. The reader will find it helpful to

refer to the following genealogical table. It will be seen that there are three great families—(1) The Aramean, which became the source of most of the alphabets of Western Asia; (2) The Sabæan, or South Semitic, from which sprang the alphabets of India; (3) The Hellenic, which became the parent of the alphabets of Europe.

The early history of the alphabet has to be reconstructed from inscriptions. The oldest forms of the Phœnician letters are seen in the inscriptions on certain bronze vessels dedicated to Baal Lebanon, which are attributed to the 11th century B.C. Next come the Moabite stone, one of the most important of Semitic epigraphs, written in a language closely resembling the Hebrew of the Old Testament, assigned to the 9th century; the bilingual lion weights from Nineveh, to the 8th; the Siloam inscription, to the 7th; and the Eshmunazar sarcophagus, to the 5th. The Phœnician alphabet gradually died out with the decline of the Phœnician empire and commerce, lingering on, in the Spanish colonies of Carthage, till the 3d century A.D., and leaving as its only direct descendant the alphabet used in the sacred books of the Samaritans.

Among the Semitic races it was superseded by the Aramean alphabet, which, arising in Northern Syria about the 7th century B.C., became the commercial alphabet of Western Asia. After an existence of seven or eight centuries, it broke up into a number of national alphabets, of which the most important are the square Hebrew, the Syriac, the Arabic, the Pehlevi, and the Mongolian, which owe their diffusion and their permanence to the fact of their having become the scripts of five of the great faiths of Asia—Judaism, Christianity, Mohammedanism, Zoroastrianism, and Buddhism.

The distinguishing peculiarity of the Aramean alphabet and its descendants lay in the opening out of the loops and the disappearance of the bars which characterise the Phœnician letters. Thus the Phœnician loops which have been faithfully preserved in our own letters B, D, O, Q, R, have disappeared in the corresponding Hebrew letters, as well as in their Arabic equivalents (see table).

The greater part of the Jewish Scriptures must have been written in the alphabet seen in the inscriptions on the Moabite stone and in the Siloam tunnel, which is practically identical with that used by the Phœnicians. On their return from the captivity at Babylon, the exiles brought

ORIGIN OF THE ALPHABET.

ACCORDING TO DE ROUGÉ.

- I. Egyptian Hieroglyphics, facing to the left.
- II. Egyptian Hieratic characters, facing to the right.
- III. The oldest Phœnician letters, mostly from the Baal Lebanon inscription.
- IV. The oldest Greek letters, from inscriptions at Thera and Athens, reading from right to left.
- V. The lapidary Greek alphabet at the time of the Persian war, reading from left to right.
- VI. Greek uncials, from the Codex Alexandrinus about 400 A.D.
- VII. Greek minuscules.
- VIII. The old alphabet of Italy.
- IX. Lapidary Latin alphabet at the time of Cicero.
- X. Latin uncials and minuscules.
- XI. Modern square Hebrew, derived from the Phœnician letters in Col. III.

with them the Aramean script used in the valley of the Euphrates. After the 1st century B.C. this alphabet developed into two branches—the northern, which became the parent of the Syriac alphabets; and the southern, which developed into the square Hebrew. This assumed its present style only about the 12th century, and is thus one of the most modern of existing alphabets, and not, as was formerly believed, the most ancient of all. The Hebrew vowel-points date from about the 7th century. The Syriac arose out of a form of the Northern Aramean alphabet, locally employed at Edessa, which was a great seat of Christian learning. The older form of Syriac, which enshrines an important Christian literature, is called the Estranghelo. This developed into a more curious style called the Peshito, which is still used by the Christians of Aleppo. A curious descendant of the Syriac alphabet is the Mongolian, which arose indirectly out of the heresy of the Nestorians, who, being condemned by the Council of Ephesus in 431 A.D., took refuge in Persia, whence their missionaries penetrated into the remotest parts of Asia, carrying with them their alphabet, which became the parent, on the one hand, of the Karshuni, used by the Christians of St Thomas on the Malabar coast of India, and, on the other, of the Mongolian, Kal-muck, and Manchu alphabets, which stretch intermittently across Northern Asia from the Volga to the Sea of Japan. Prior to the extension of Mohammedanism, the Mongolian was the official alphabet of the vast empire of Genghis Khan, and was used in Khiva and Bokhara, which now employ the Arabic. The Mongolian is written in vertical columns, from the top to the bottom of the page, instead of from right to left, like the Syriac, Arabic, and Hebrew.

In the valley of the Euphrates, the Aramean alphabet gradually exterminated the cumbrous Cuneiform scripts, and became the parent of the Iranian family of alphabets, which are known chiefly from the coins and inscriptions of the Parthian and Sassanian kings who ruled Persia from the 3d century B.C. to the Mohammedan conquest in the 7th century A.D., when Arabic became the script of Persia. The old Persian or Pehlevi writing was taken to India by fugitives from Islam, and is still used by the Parsees, or fire-worshippers of Bombay, for their sacred books.

In the 5th century A.D. the western or Arsacidan form of the Pehlevi alphabet, which is akin to the Palmyrene alphabet used in the inscriptions of Zenobia, was reformed and adapted to the use of the Armenians by St Mesrob, who also constructed the Georgian alphabet out of the eastern or Sassanian form of the Pehlevi writing. But the most interesting offshoot of the Iranian alphabet was the Bactrian, which, before the conquests of Alexander, extended over the eastern provinces of the Persian realm to Merv, Herat, and Bokhara, and even reached the Punjab, which formed the Indian satrapy of the empire of Darius. The chief monument of the Indo-Bactrian alphabet is the long inscription engraved on a rock near Peshawar by Asoka, the great Buddhist emperor, who reigned in the 3d century B.C.; but it can be traced by means of the coins of the Indo-Scythian kings nearly to the close of the 1st century A.D. It has left a curious survival in the numerals which we ordinarily use. These, which we call the Arabic ciphers, are really of Indian origin, having been brought from India by the Arabs, and introduced by them into Spain, whence, during the 12th and 13th centuries, they spread over Europe, gradually replacing the more clumsy Roman numerals. Thus our cipher 5 is the Indo-Bactrian letter *p*, the initial of the Sanskrit word *pañchan*, five (cf. Greek *pente*). Our 4 is the letter *ch*, the initial of the Sanskrit *chatur*,

four (cf. Latin *quatuor*), and 7 is an *s*, the initial of *saptan*, seven. Few things in the history of the alphabet are more curious than the fact, first discovered by Dr Isaac Taylor, that the numeral signs of Europe and America are the letters of an obscure alphabet introduced into India 2400 years ago as a consequence of the conquests of Darius.

The Iranian alphabets of Central Asia were suddenly exterminated by the Arabic, whose rapid diffusion was one of the most remarkable results of the spread of Islam. It extends from Morocco to Sumatra, from Bokhara to Zanzibar, and, with some trifling modifications, it has been adapted to express the sounds of languages as diverse as Arabic, Turkish, Persian, Pushtu, Beluchi, Hindustani, and Malay.

As the square Hebrew and the Syriac arose out of the local alphabets of Jerusalem and Edessa, so the Arabic, next after the Latin the most important alphabet in the world, was originally only the local alphabet of Mecca. It has two forms—the Kufic, a monumental script now almost disused; and the Neski, which is the cursive Arabic in ordinary use.

There were two early alphabets in Arabia. The Arabic is descended from the Nabathean, an Aramean alphabet of Northern and Central Arabia, known to us chiefly from inscriptions, dating from the 1st to the 5th century A.D., engraved on the rocks of Petra and Sinai. On the other hand, numerous inscriptions, some as old as the 2d century B.C., chiefly from the neighbourhood of Aden, show that a very different alphabet, called the Sabeen or Himyaritic, was employed in Arabia Felix. It seems to have been derived from the alphabet of Tyre, and may probably have been obtained as early as the time of Hiram. Carried to the opposite coast of Africa, it became the parent of the alphabets of the Abyssinian Christians, called the Ethiopic and the Amharic, in which new letters have been added, and their order and some of their names changed, while the alphabet has been converted into a syllabary.

But the chief interest of the Sabeen alphabet arises from its having become the parent of the modern scripts of India, which comprise more than half of the existing alphabets. We have already seen that an Aramean alphabet was introduced into the Punjab through Afghanistan about 500 B.C., but this was ultimately replaced by an offshoot of the alphabet of Yemen, which, about the same time, must have been brought to the ports of Western India by Arabian merchants. From the inscriptions of Asoka, the Constantine of India, whose edicts, engraved on rocks and pillars, extend across the whole breadth of India from Gujarat to Orissa, we obtain a knowledge of the ancient type of the Indian alphabet. In the hands of the early Indian grammarians it became the most perfect scientific alphabet of the world. Consisting of forty-two letters—thirty-three consonants and nine vowels—it is capable of expressing the most delicate gradations of the Sanskrit sounds.

The developments of the primitive Indian alphabet may be traced, by means of inscriptions, from the time of Asoka, in the 3d century B.C., to the 10th century A.D., when the prototypes of the present provincial alphabets of India had established themselves. The existing vernacular alphabets divide themselves into four well-marked groups: (1) The Pali, or Buddhist, comprising alphabets used in Ceylon, Burma, Siam, Pegu, Cambodia, Java, and Korea. (2) The Nagari, or Hindu, of which an old form is used for Sanskrit books, and to which belong the local alphabets of Northern India, including those of Bengal, Kashmir, Nepal, Tibet, Gujarat, and the Punjab. (3) The Dravidian, used in Southern India, of which the Tamil and Telugu are the chief varieties. (4) The Malay, used in Celebes, the Philippines, and Sumatra. See DEVANAGARI, WRITING.

The alphabet of Southern Arabia, the parent of the numerous Indian scripts, branched off from the Phœnician stem about the 10th century B.C., a date which must also be assigned to a still more important offshoot of the Phœnician. This was the Hellenic branch, the source of the alphabets of Europe and America. A Greek legend refers the introduction of the alphabet to Cadmus, the Tyrian. Cadmus is an eponymic name, meaning in Semitic speech 'the man of the East.' Herodotus tells us that Cadmus landed first in Thera, an island in which the oldest Greek inscriptions have been found. But this legend is a very small portion of the evidence for the Phœnician origin of the Greek alphabet. It is established by the forms of the letters, which in the oldest Greek inscriptions do not differ appreciably from those in early Phœnician records; by the order of the letters, which is the same in the Greek and Phœnician alphabets; and also by their names, which are significant Semitic words, though meaningless in Greek. Thus Alpha

is the Semitic *aleph*, an ox; Beta is *beth*, a house; Gamma is *gamel*, a camel; Delta is *daleth*, a door; Epsilon is *he*, a window; Eta is *cheth*, a fence; Theta is *teth*, a serpent; Iota is *yod*, a hand; Kappa is *kaph*, the palm of the hand; Lambda is *lamed*, an ox-goad; Mu is *mem*, the waters; Nu is *nun*, a fish; O-micron is *Ayn*, an eye; Pi is *pe*, the mouth; Rho is *resh*, the head; and Tau is *tau*, a mark or cross.

A knowledge of alphabetical writing must have been obtained by the Greeks from the Phœnician trading settlements in the Ægean, as early as the 10th century B.C. At the date of the oldest Greek inscriptions which are extant, three vowels, *alpha*, *epsilon*, and *omicron*, had already been evolved out of the Phœnician breaths, *aleph*, *he*, and *ayin*, and two, *iota* and *upsilon*, from the semi-consonants *yod* and *vau*. The forms of the letters had undergone hardly any change, and the direction of the writing is still retrograde, from right to left, as in the Semitic scripts. Somewhat later, the direction is *boustrophædon*, or 'ploughwise,' the lines proceeding alternately from right to left, and from left to right, just as the plough draws the alternate furrows in opposite directions. Before the close of the 7th century, the more convenient plan of writing all the lines from left to right was adopted.

By the middle of the 6th century, the Greek alphabet had in all essential respects attained its final development. The letters had assumed the forms of the Greek capitals with which we are familiar; two additional vowels had been evolved, *eta* from *cheth*, and *omega* from *omicron*; *phi* had been differentiated out of *theta*, *chi* out of *kappa*, and *psi* probably out of *phi*; while *F*, *Q*, and *san*, descended from *vau*, *goph*, and *tsadde*, were disused as letters, though they were still retained as numerals. About the 3d century B.C. the lapidary characters, which correspond to the capitals in Greek printed books, began to be replaced by more rounded forms which are called uncials, while cursive forms were used for correspondence. Finally, between the 7th and 9th centuries A.D., the minuscules, which are the small letters of our printed Greek books, were evolved from a combination of uncials and cursives.

The foregoing account refers to the Ionian alphabet, which grew up on the coasts of Asia Minor, and was adopted as the alphabet of Athens in 403 B.C. But the Greek alphabet, from a very early time, shows a tendency to separate into two types—the Eastern or Ionian, which became the classical alphabet of Greece; and the Western or Chalcidian, which was the source of the alphabet of Italy. The chief differences between the two are those which still distinguish our own from the Greek alphabet. In the Western alphabet, *F* and *Q* were retained; *H* continued to be a breath, instead of developing into a vowel; and the forms of *l*, *r*, *p*, *x*, *s*, became *L*, *R*, *P*, *X*, *S*, instead of *A*, *P*, *I*, *E*, *Z*.

The primitive alphabet of Italy, from which our own is derived, belonged to the Western Greek type. As early, probably, as the 9th century B.C., it was carried by the Chalcidians of Eubœa to Cumæ, near Naples, which was a colony of Chalcis. It became the parent of five local Italic alphabets—the Oscan, the Etruscan, the Umbrian, the Faliscan, and the Latin. Owing to the political supremacy of Rome, the Latin ultimately displaced the other national scripts of Italy, and became the alphabet of the Roman empire, and afterwards of Latin Christendom, thus spreading over Western Europe, America, and Australia, and becoming the dominant alphabet of the world; its only rival as a cosmopolitan script being the alphabet of the Koran.

Curiously enough, this, the most modern of alphabets, has adhered more closely than any

other to the primitive Phœnician type. Of the Phœnician letters, the Greek alphabet discarded three and added five, while the Latin has only discarded two and added three. Its archaic character is shown by the use of the older forms, L and S, instead of Δ and Σ, and by its retention of the older value of H, and of the letters F and Q, which the Greek alphabet has lost. But it lost φ, χ, and θ, as letters, whose Western forms, however, are retained as the Roman numerals, M, L, and C.

At the time of the early empire, the Romans employed two forms of their letters—capitals for inscriptions; and for business and correspondence, degraded cursive forms, which are known to us chiefly from *graffiti* scribbled by schoolboys on the walls of Pompeian houses. These two Roman scripts are respectively the sources of our own printed capitals, and of our printed minuscules or small types. Out of the Roman cursive, the Irish semi-uncial was developed as a book-hand about the 6th century A.D. Through Scotland it was introduced into Northumbria by Irish monks, and became the basis of the beautiful Caroline minuscule, so called because it arose in the reign of Charlemagne, in the calligraphic school at Tours, founded by Alcuin of York.

Owing to its intrinsic merits, consisting in its legibility, and the ease with which it could be written, the Caroline minuscule rapidly became the book-hand of Europe; but, after the 12th century, it began to degenerate into the black-letter, which was imitated in the types of the earliest printers, and is still retained in some German books. The Roman printers, however, reverted to the better Caroline forms, which now go by the name of 'Roman' type. These types were brought to Paris in 1470, and fifty years later to England, where they displaced the black-letter which had been previously used.

The wide difference existing between the forms of our capital and smaller letters is thus explained. We have, in fact, two alphabets, both dating from the 1st century A.D., in concurrent use. Thus the forms a, b, d, r, g, m, h, are derived from the old Roman cursive, while A, B, D, R, G, M, H, are the Roman capitals. In d, the loop of D has been transferred from the right to the left of the vertical stroke; in g, two new loops have been formed, the little crook at the top being all that remains of G; in b, the upper loop of B opened out, and ultimately disappeared; in r, the loop and tail of R have undergone nearly complete atrophy; while in f, the tick to the left is all that remains of the lower curve of S (see table).

In our own alphabet, the order of the letters does not differ very greatly from the Phœnician arrangement, but the few changes are historically instructive. The last Phœnician letter was t, which in our alphabet is followed by six letters, u, v, w, x, y, z. Of these, u dates from the 9th century B.C., having been differentiated by the Greeks out of F, and placed after t, the last of the old letters. Originally, u and v were only the medial and initial forms of the same letter. In the 10th century A.D. the first came to be used for the vowel, and the second for the consonant, because in Latin words the consonant usually occurs at the beginning, and the vowel in the middle of words, and the two forms were regarded as separate letters, and placed side by side in the alphabet. So also with w, which arose in the 11th century as a ligature, like æ, fi, or &, the ligature for et. It was originally written vv, and then ww, out of which W arose. These new forms were squeezed in, so to speak, between u, the last of the old Greek letters, and X, the last of the original Latin letters. The letter x was developed out of *samekh* (s), about the 7th century B.C., and

was placed at the end of the old Latin alphabet. In the time of Cicero, the Romans borrowed Y from the Greek alphabet, to denote the sound of *upsilon*, and placed it at the end of the alphabet after X. Soon afterwards, Z was also borrowed from the Greek alphabet and placed after Y. It was introduced into the English alphabet from the French in the 15th century, being only used in English, as in Latin, to spell words of foreign origin. The letters I and J, like U and V, were the medial and initial forms of the same letter; but since the consonantal sound usually occurs at the beginning of words, and the vowel-sound in the middle, J was conveniently appropriated in the 15th century for the consonant, and I for the vowel. The dot of j, which is needless, is a mere survival, showing that the two forms were differentiated after the practice of dotting the i had come into vogue. In the 11th century, the letter was accented, i, for convenience, when it came next to u, m, or n; in the 14th, the accent was changed to a dot; and it was only in the 15th that the dot became universal. In the Latin and English alphabets, the seventh letter is g; while in the Phœnician, as well as in the Greek, the seventh letter is z. We have already seen why z was removed to the end of the alphabet. The third letter originally had the value of g, but its symbol, C, came in Latin to have both sounds, c and g. This was inconvenient, and the form G was differentiated out of C, to denote the latter sound, and was transferred in the 3d century B.C. to the seventh place, hitherto occupied by z, which had fallen out of use, not being required for Latin words, and was only reborrowed two hundred years later for the transliteration of Greek words.

The Anglo-Saxons adopted into their alphabet two of the Runes, þ, called *wen*, for w, and þ, called *thorn*, for th. The first was disused after the invention of W, but the other is still occasionally employed by old-fashioned people, who write 'ye' for 'the,' the Y-shaped letter being merely a survival of the *thorn* Rune. See THORN.

In the Latin alphabet, the vowels are called by their sounds; the consonants, by the sound of the letter combined with the easiest vowel, which, for convenience of utterance, precedes the continuants and follows the explosives. Thus we have *ef*, *el*, *em*, *en*, *er*, *es*, but *de*, *de*, *ge*, *pe*, *te*, because *ef* is easier to pronounce than *fe*, while, on the other hand, *be* is easier than *eb*. The sounds of k, h, g, which are pronounced farther back, are each combined with the appropriate back vowel, for facility of pronunciation. The name of z is an exception to the rule. We call it *zed* and not *ez*, because the letter, with its Greek name *zeta*, was introduced into the Latin alphabet from the Greek after the Latin letters had acquired the names from which our names are derived.

The Greek alphabet was the source not only of the Latin, but of the other national alphabets of Europe. The Runes (q.v.), which formed the alphabet of the Scandinavian nations, were based on early forms of the Greek letters, which, as Taylor showed, were obtained about the 6th century B.C. from Greek colonies on the Black Sea, by Gothic tribes who then lived south of the Baltic. The Ogams (q.v.), used in the earliest inscriptions of Wales and Ireland, seem to have been based upon the Runes. The Mæso-Gothic alphabet was constructed by Ulphilas in the 4th century, by a combination of the Runes and the contemporary Greek uncials. The Coptic alphabet, used in Egypt, was also derived from the Greek uncials of the 4th century A.D., with six additional characters borrowed from the Egyptian Demotic, a cursive script derived from the hieroglyphic writing. The Slavonic alphabets, of which the Russian is the most

important, were obtained from the 9th-century Byzantine uncial, with some additional characters derived from ligatures employed in the Greek cursive writing. The obscure Albanian alphabet is merely a debased form of minuscule Greek.

Brit.*, 11th ed. For a summary of various theories of the origin of the alphabet, see Dr Peter in *Journal of American Oriental Studies*, vol. xxi.

Alpheus (*Rufes*) is the chief river of Peloponnesus (Morea), rising in the SE. of Arcadia, and flowing past the famous Olympia westwards into the Ionic Sea. In its passage through Arcadia, a country consisting of cavernous limestone, it repeatedly disappears under ground and rises again. With this fact was connected a remarkable myth. The river-god Alpheus was said to have become enamoured of the nymph Arethusa while bathing in his stream. To escape him, she prayed to Artemis, who changed her into a fountain, and opened up an underground passage for her to Ortygia, a small Sicilian island in the harbour of Syracuse. The river still pursued the nymph, passing from Greece to Sicily below the sea, without mingling his waters with it, and appearing in the spring that bubbles up by the shore, close by the fountain of Arethusa.

Alpine Climbing. De Saussure, in virtue of his ascent of Mont Blanc (August 1787), and the published account thereof, may be looked upon as the father of mountaineering. For many years, however, climbing was almost confined to this peak, and the amusement was little appreciated. Albert Smith (who ascended Mont Blanc in 1851) stimulated public curiosity, but the real development came with the formation of the Alpine Club in 1857-8, and the publication of *Peaks, Passes, and Glaciers* in 1859. Mountaineering then at once sprang into fashion. Nor was this to be wondered at. Practically, a new pleasure had been invented—health-giving and adventurous. The Alps were easily accessible, and the natives of the country were so far civilised, that the traveller who could put sufficient money in his purse had nothing to fear. The first pioneers of the Alps were explorers and geographers, rather than climbers; but, as was only natural, the high mountains soon began to attract, and many found pleasure in climbing for its own sake. The natives of the alpine valleys, speaking generally, were expert mountaineers, and a race of instructors was therefore ready to hand. Gradually mountaineering as an art began to develop, and gradually the real began to be dissociated from the imaginary dangers of the Alps; for beyond question, a certain amount of risk was run, but it was found that this could be minimised by experience and acquired skill. It is no exaggeration to say that the first accident on the Matterhorn, in 1865, did much to popularise the amusement, which only needed the advertisement of a little hostile criticism. Cavillers questioned what the pleasure might be; and hinted that vanity was at the bottom of it. The Alpine Club itself furnishes one answer, for it numbers over 700 members, including men of the most varied tastes and pursuits in life, whom probably no other bond on earth, save the fascination of mountaineering, could have united together. The charm is very

composite in its nature. The mere healthiness of the pursuit, no doubt, attracts many. Again, there is always pleasure in overcoming natural difficulties by acquired skill; and the feeling that by doing a thing in the right way, real risks can be to a great extent abolished, is in itself alluring. As an illustration, may be instanced the use of the rope, especially on snow mountains. If three persons were to walk up such mountains as Mont Blanc or the Jungfrau without using the rope, or without using it properly, they would be in continual peril; united together at intervals of ten or twelve feet, the party should be perfectly safe from all dangers of slips and crevasses. Mountaineering has opened up what would otherwise be the *terra incognita* of the regions above the snow-line, with all their wild beauty and grandeur, and has made them accessible to the many. Despite its ever-increasing toll, fatal accidents among members of the English Alpine Club are exceedingly rare, only three deaths from mountaineering being recorded in the ten years ending 1913.

But still there are real dangers, which cannot be wholly eliminated even by the most skilful climber. The mountaineer who refuses to recognise that such is the case, runs the greatest risk of all. No man takes proper precautions who undertakes an expedition which, under favourable conditions, is only just within his powers. Unexpected difficulties may occur, and the climber who has no reserve to draw upon, is at every instant in grave peril; and so too are all the members of his party. Some knowledge and judgment of the weather are indispensable. The easiest mountain may become most formidable in a storm or a gale of wind. But for those who have the courage of their opinions, and are not afraid to turn back and abandon a half-completed expedition, or who decline to start under unfavourable conditions, bad weather need have little terror. The risk of avalanches is greatest in the spring and winter, and least in the summer months, when the Alps are chiefly visited. Experience alone will teach a man where and at what time of day, on any particular mountain, avalanches are most prone to fall. On rock mountains—and these attract chiefly on account of their greater variety—there is, on the whole, perhaps, less risk to run, though bad weather is equally formidable. The rope is less valuable, but it is less needed, since the climber has hand as well as foothold. Falling stones constitute a real but still a much exaggerated danger. The difficulties of descending a peak are, broadly speaking, as great as, but not greater than, those of ascending; but men are apt to become careless when the main object of an expedition is achieved, and directly inattention creeps in, the risk begins. Mountain vertigo is much rarer than is commonly imagined. The climber is not perpetually walking along the edge of unfathomable precipices. Probably but few members of the Alpine Club could stand on the edge of a parapet, and look down a height of say 100 feet, without feeling uncomfortable, and yet they may have ascended most of the great peaks of the Alps, without ever having experienced any sensation of the sort. No doubt the moral support of the rope accounts in part for this, but the real fact is that there are few places in the Alps where the climber's nerves are tried as in the imaginary position pictured.

Of the special equipment required, the most essential items are reliable boots, properly nailed. A man unsuitably shod runs more risk in walking alone over a steep dry grass slope, than in climbing the Matterhorn, provided he has a sufficiency of practised guides, is properly equipped, and is in good condition. The use of the ice-axe or of the

alpenstock has to be learned like that of the oar or the cricket bat—by practice. The most efficient plan, after all, of guarding against the real dangers of the Alps, consists in employing only thoroughly competent and trustworthy guides; yet it must be borne in mind that guiding too is an art, and it by no means follows because a man is an expert climber, that he is fit to take charge of a party. Alpine Clubs have done much to raise the standard of guides, and to ensure the safety and comfort of climbers by the provision of mountain huts and the dissemination of information through their journals. In selecting guides for difficult expeditions, the advice of competent judges should always be taken.

The idea of founding the Alpine Club originated with Mr William Matthews. The *Alpine Journal*, by members of the club, published quarterly, began in 1863. Members are elected by ballot, if their qualifications, whether climbing, literary, artistic, or scientific, have been previously approved by the committee. In quest of new peaks to conquer, the club has extended its operations to other ranges than the Alps. Among the more famous first ascents may be mentioned those of the Matterhorn (Whymper, 1865); the Schreckhorn (Stephen, 1861); Elbruz in the Caucasus (Friesfield, Grove, 1868, 1874); Cotopaxi and Chimborazo in the Andes (Whymper, 1880); Mount Cook (Green, 1882). Sir Martin Conway climbed several Andean peaks, and in 1892 one of the Karakoram Himalayas. The Duke of the Abruzzi climbed Mt. St Elias in 1900, Ruwenzori in 1906, and almost managed K² in 1909. A Mount Everest campaign began in 1921. At its jubilee celebration the English Alpine Club claimed to be the mother of no fewer than 166 Alpine Clubs in every part of the globe, including a women's Alpine Club formed in London in 1907. An Austrian Alpine Club (1862) was followed by Swiss (1863), Italian (1863), German (1869), and other associations. Climbing is not their sole purpose; they devote themselves largely to the scientific investigation of the Alpine area. The amalgamated German and Austrian Club has over 100,000 members.

Young and others (1920); the 'Climbers' Guides' series, ed. by Conway and Coolidge (10 vols. 1900-4); Harold Raeburn, *Mountaineering Art* (1920); and books by Conway and by Coolidge.

Alpine Plants, a name given not only to plants found at elevations approaching the limit of perpetual snow in the Alps, but also to plants belonging to other mountainous regions in any part of the world, whose natural place of growth is near snows that are never melted even by the beams of the summer's sun. As the elevation of the snow-line, however, varies very much in different countries, according to the latitude, and also from peculiar local circumstances, the term Alpine Plants is not so much significant of the actual elevation of the habitat, as of the average temperature which prevails there. On the Andes, near the equator, at an elevation of 12,000 to 15,000 feet above the level of the sea, many kinds of plants are found, of humble growth, resembling in their general appearance those which occur in Germany and Switzerland at an elevation of 6000 feet; and these again either resemble, or are even identical with, the species which in Lapland grow upon hills of very little elevation, or which, in the northern parts of Siberia, are found at the level of the sea. Similar plants occur also in the Himalaya Mountains, at elevations varying remarkably within very narrow geographical limits from local causes, which also create great differences in the general dryness

or humidity of the atmosphere. The laws of this natural distribution of plants were investigated first by Humboldt, De Candolle, and others, and more recently elucidated by Warming, &c., and form the most essential part of a branch of science still in its infancy—phytogeography (see ECOLOGY, GEOGRAPHICAL DISTRIBUTION). When the alpine plants of Central Europe are spoken of, those are meant which grow at an average height of 6000 feet, marking what, in the language of distributional science, is called the alpine zone. This, on its northern limit, the Riesengebirge, falls as low as 4000 feet, and rises, in the southern Alps and Pyrenees, to an elevation of 9000 feet, and sometimes even above it. Although very rich in forms peculiarly its own, this zone contains many plants which are likewise found on much lower hills, and even in the plains. The number of these, however, diminishes as the elevation increases. Hence the small spaces clear of snow in the highest regions possess a very characteristic flora, the plants of which are distinguished by a very low diminutive habit, and an inclination to form a thick turf, frequently also by a covering of woolly hairs, whilst their stems are very often either partly or altogether woody, and their flowers are in proportion remarkably large, of brilliant colours, and in many instances very odoriferous, upon which accounts they remarkably attract and please the occasional visitors from the plains. In the Alps of Central Europe, the eye is at once caught by gentians, saxifrages, rhododendrons, and various species of primrose, as well as by the rarer edelweiss—*Gnaphalium* (*Leontopodium*) *alpinum*. With these and other phanerogamous plants are associated a number of delicate ferns and exceedingly beautiful mosses. The highest mountains in Scotland exhibit a somewhat similar flora, and beautiful plants, both phanerogamous and cryptogamous, are found on them, which never appear in lower situations, as the Alpine Speedwell (*Veronica alpina*), the small Alpine Gentian (*Gentiana nivalis*), the Rock Scorpion Grass, or Alpine Forget-me-not (*Myosotis alpestris*), *Azalea procumbens*, *Woodsia vivensis* and *hyperborea*, &c. Many alpine plants are limited to a very small district. Thus, the flora of Switzerland differs considerably from that of Germany, the latter being now known to contain 3400 phanerogamous plants, of which the former contains 2200, and along with them also 126 species which have hitherto been found only in the Swiss Alps.—There are, moreover, particular species of plants which are found only in single localities, as *Hypericum cors*, upon the Wiggis Mountains in the canton of Glarus; *Wulfenia carinthiaca*, upon the Kuweger Alp, in Upper Carinthia; and many others. There are, however, many species which, occurring on the mountains of Central Europe, appear also in those of Britain and Scandinavia at lower altitudes, but are not found in the intervening plains. The colonies of alpine plants on mountainous regions are the survivors of the widespread arctic-alpine flora of glacial periods, which saved themselves in low latitudes by retreating to the heights upon the disappearance of cold climatic conditions from the low grounds. Cryptogamic plants are generally found in alpine regions in much greater abundance than elsewhere. The great beauty of Alpines, even when dried, makes them favourites with those plant-collectors who have amusement more in view than the mere interests of science. Small herbaria of them are offered for sale everywhere in Switzerland; and in some places large collections have been prepared and thrown open to the public. The introduction of alpine plants into our gardens was formerly attended with difficulty, and success in establishing

them was limited; but thanks to improved facilities in travelling, the extension of rapid means of communication, and, above all, to the dissemination of correct views of the requirements of these beautiful wildings under cultivation, there is now nothing to prevent our having the alpine flora of the world well and fully illustrated in our gardens. In fact, the progress that has been made, since about 1870, in introducing and successfully establishing species that were prior to that time considered incapable of existing out of their own peculiar habitats, is perhaps the most remarkable achievement of modern gardening art. The specially important collections in our leading botanical gardens are becoming yearly more rich in new species, by importation from their native wilds; and many of those that have been some time under cultivation, are developing varieties with distinctive characteristics of feature and constitution—a sure sign that the plants are tractable and amenable to the circumstances of cultivation. The number of private collections of alpine plants in Britain has greatly increased also within the past few years, and nurserymen are devoting more attention to their culture, showing that taste in flower-gardening is strongly tending in a more intellectual and satisfying direction, to all who take an interest in the art. The rich variety in colour and form, and the strongly-marked individuality that may be introduced into every flower-garden by employing freely these lowly but brilliant inhabitants of alpine regions in its embellishment, will mark a new era in English flower-gardening. Many alpine flowers, especially edelweiss and the alpine rose, threaten to become extinct in their native haunts, and in 1887 the government of Valais made inclosures for the protection and cultivation

of these plants. For easy scientific introduction, see Schimper's *Plant Geography* and Warming's *Ecology*. Alpine Floras are numerous.

Alpini. See BERSAGLIERI.

Alpin'ia. See GALANGALE.

Alpnach, or ALPNACHT, a Swiss village, in the canton of Unterwalden, at the foot of Mount Pilatus, 1½ miles from that part of Lake Lucerne called Lake Alpnach. It is known principally on account of its celebrated 'slide,' now disused, which was 8 miles long, and by means of which timber was brought from the forests of Mount Pilatus to the village.

Alps (possibly a Celtic word meaning 'high,' cf. Gaelic *alp*, 'a high mountain'; or connected with Lat. *albus*, 'white'), the most extensive system of lofty mountains in Europe, raising their giant masses on a basis of 90,000 sq. m., between 6° 40' and 18° E. long., and extending in some places from the 44th to the 48th parallel of latitude. The Alpine system is bounded on the N. by the hilly ground of Switzerland and the upper plain of the Danube; on the E., by the low plains of Austria; on the S., by the Adriatic Sea, the plains of Lombardy, and the Gulf of Genoa; and on the W., by the plains of Provence and the valley of the Rhone. A string of lakes encircles both the northern and southern bases of these mountains, the former at an elevation of 1200 to 2000 feet; the latter, 600 to 700 feet. The varied natural scenery of France, Italy, Germany, and Austria has a common centre of union in this lofty region. Valleys open out in all directions, sending their melted snows on one side into the North Sea, on another into the Black Sea, and on another into the Mediterranean.

The *water-system* of the Alps may be thus briefly

The Chain of Mont Blanc from the Flegère across the Valley of Chamouni.

sketched: (1) In the basin of the Rhine there is the Rhine itself, which partly forms the Lake of Constance, at the north-eastern extremity of Switzerland, and receives on the left the important tributaries of the Thun and the Aar; the latter of which flows through Lakes Brienz and Thun, and is itself augmented by various affluents, the largest of which are the Reuss and the Limmat. (2) In the basin of the Danube there flow from the south the Iller, Lech, Isar, and the Inn. Still farther east, the Danube has for its tributaries the Traun, the Ens, the Raab, the Drave, and the Save, the last three of which have their sources in the extreme Eastern Alps. (3) In the basin of the Po, there

are numerous streams which rise in the Southern Alps; the principal of these are the Dora Baltea, the Ticino from Lake Maggiore, the Mincio from Lake Garda, and the Adige. (4) In the basin of the Rhone, there are the Rhone (flowing through the Lake of Geneva), and various Alpine tributaries, the most important of which are the Arve, the Isère, and the Durance. (5) The Var is the principal Ligurian coast-stream; the Piave, and the Tagliamento, the largest of those which fall into the Adriatic from the Southern Alps.

Divisions.—In order to give a clear view of the manifold ranges of this mountain-land, a distinction is generally made between the East, the West, and

the Middle Alps; the last of which is again divided into a northern, central, and southern chain; while a natural separation by river-valleys into groups is also made. I. WEST ALPS.—The principal ranges of these are: (1) The Maritime Alps, extending from the middle Durance southwards to the Mediterranean, and rising in the Aiguille de Chambeyron to a height of 11,155 feet. (2) The Cottian Alps, north of these, whose highest summit, Monte Viso, is 12,605 feet. (3) The Dauphiné Alps, separated by the valley of the Durance from the Cottian; their highest summit is the Pic des Ecrins, 13,462 feet. (4) The Graian Alps, forming the boundary between Savoy and Piedmont, and attaining in the Grand Paradis, an elevation of 13,300 feet. II. MIDDLE ALPS. *Central Chain*.—(1) The Pennine Alps, between the plains of Lombardy and the valley of the Rhone. Highest summits: Mont Blanc, 15,732 feet; Monte Rosa, 15,151 feet. (2) The Lepontian or Helvetic Alps, from the depression of the Simplon, along the plateau and masses of St Gotthard, to the pass of Splügen. (3) The Rhaetian Alps, between the Inn, the Adda, and the Upper Adige. *Northern Chain*.—(1) The Beinese Alps, between the Rhone and the Aar. Highest summits: Finsteraarhorn, 14,026 feet; Aletschhorn, 13,803; Jungfrau, 13,671 feet. (2) The Alps of the Four 'Forest Cantons,' the Schwyz Alps, &c. *The Southern Chain*.—(1) The Ortler Alps, between the Adda and the Adige. (2) The Trientine Alps, between the Adige and the Piave. III. EAST ALPS.—The principal chains of these are: (1) The Noric Alps, between the plains of the Drave and the Danube. (2) The Carnian Alps, between the Drave and the Save. (3) The Julian Alps, between the Save and the Adriatic Sea.

A comprehensive classification leads to a division of the elevations into three regions: (1) The lower range forming the buttresses of the main masses, and reaching a height of 2500 to 6000 feet; that is, to the extreme limit of the growth of wood. (2) The middle zone lying between the former limit and the snow-line, at the elevation of 8000 to 9000 feet. (3) The high Alps, rising to 15,732 feet. The middle zone forms the region of mountain-pasturages, where the characteristic Alpine dairy-farming is carried on. These pastures consist of a rich carpet of grass and flowers. This threefold division of heights, however, does not everywhere coincide with the same phenomena of vegetation: the line of perpetual snow descends lower on the north side, and the boundaries of the zones above described vary accordingly. (1) The line of demarcation between the region of mosses and alpine plants and that of perpetual snow, is from 8000 to 9000 feet on the northern declivities; but on the southern, it approaches 10,000 feet. (2) The highest limit to which wood attains on the north is about 6000 feet, while on the south it is nearly 7000 feet. (3) Grain, beech, and oak, on the north, disappear at the elevation of 4000 feet; on the south, they contrive to exist some hundreds of feet higher. (4) The region of the vine, as well as of maize and chestnuts, extends to an elevation of 1900 feet on the northern declivity; and on the southern declivity to 2500 feet. The ranges of outlying lower mountains which flank the high central Alps on the north, east, and west, are mostly wanting on the south, especially where the Middle Alps descend into the plains of Lombardy. Thus the Alps rise in steep rocky precipices from the level of the flat plains of the Po, whilst they sink more gradually into the plains on the north; hence their mighty masses, closely piled together, present an aspect from the south more grand and awful; from the north, more extended and various.

Valleys.—The depth of the valleys, and their variety as to form and arrangement, are not less

striking than their elevations. Most worthy of notice is the characteristic form of the wide longitudinal valleys that lie at the foot of the high central chains. On the east side, they open directly into the plain; on the north, they are connected with the plain through transverse valleys which often end in lakes. The transverse valleys on the south side are mostly in the shape of steep rocky ravines, forming in some parts long-stretching lakes. Besides the deep-sunk principal valleys, there are extensive series of basin-shaped secondary valleys, which are the scenes of Alpine life, properly so called. Many of the Alpine valleys have names distinct from the rivers flowing through them. Thus, the valley of the Rhone is styled the Upper and Lower Valais; that of the Adda, the Valtelline; of the Arve, Chamounix.

Communications—Passes.—The valleys of the high Alps form the natural means of communication. Some are more accessible than others. The entrance into a longitudinal valley is almost always smooth and easy; art has often had to force an entrance into a transverse valley. On many of the high-roads which link the principal with the secondary valleys, it has been found necessary to blow up long ridges of rock, to build terraces, to make stone bridges and long galleries of rock as a protection against avalanches, as well as to erect places of shelter (*hospices*) from storms. The construction of these roads may be reckoned among the boldest and most skilful works of man. In crossing the Alps, several defiles (usually seven) have to be traversed; for in addition to the pass of the main crest, there are other defiles on both sides, at the entrances of the different valleys. In the east, the number of these narrow passes or defiles is considerably increased. The names applied to the Alpine passes vary according to their natural features or the local dialect; as Pass, Sattel (Saddle), Joch (Yoke), Scheideck, Klaus, Col, Chiusa. The traveller, in the course of a day's journey, experiences a succession of climatic changes, which is accompanied with an equal variety in the manners of the people.

No lofty mountains in the world are more easily crossed than the Alps; of late years the Mont Cenis, the Brenner, and the St Gotthard railways into Italy from the north afford special facilities. Hence we can understand how the plains of Upper Italy, accessible from the French, German, and Austrian sides, have for ages been the theatre of bloody strife. The passage of the WEST ALPS is made by five principal roads: (1) The military road, La Corniche, a coast-road at the foot of the Alps from Nice to Genoa, parallel to which a railway now runs. (2) The causeway over the Col-di-Tenda, between Nice and Coni, made in 1778; highest point, 6158 feet. (3) The high-road over Mont Genève, connecting Provence and Dauphiné with Turin; highest point, 6102 feet. (4) The carriage-road made by Napoleon in 1805, over Mont Cenis, connecting Savoy with Piedmont; highest point, 6848 feet. Near this the chain is pierced by the railway tunnel opened in 1871 (see TUNNEL, and CENIS). (5) The pass of the Little St Bernard, connecting Geneva, Savoy, and Piedmont; highest point, 7190 feet. Besides these great roads, there are many smaller ones branching off from them, which form a pretty close network of communication. It has been debated whether Hannibal crossed the Cottian Alps by the Cenis, or the Graian by the Little St Bernard. The passage of the MIDDLE ALPS is made by eight principal roads. (1) That of the Great St Bernard, connecting the valley of the Rhone with Piedmont; highest point, 8120 feet. It was crossed by Napoleon in 1800. (2) The magnificent road over the Simplon, constructed by Napoleon, 1801-6,

and connecting the Valais with the confines of Piedmont and Lombardy; highest point, 6595 feet. The project, long in contemplation, of effecting another junction of the Swiss and Italian railways, was realised by the opening in 1906 of a tunnel through the Simplon. (3) Between the Great St Bernard and Monte Rosa is the Matterjoch, connecting Piedmont with the Valais. (4) The pass of St Gotthard, connecting Lucerne with Lago Maggiore; highest point, 6936 feet. The St Gotthard (q.v.) Railway tunnel was opened for traffic in 1882. (5) The Bernardino Pass, made 1819-23, by the Swiss Grisons and Sardinia; highest point, 6769 feet. (6) The Splügen Pass, repaired in 1822, connecting the sources of the Rhine with the Adda. This pass was the one used by the Romans in their intercourse with the countries bordering on the Danube and the Rhine, and also by the German armies in the middle ages. (7) The Wormser Joch, or the Ortler, opened by Austria in 1824. It connects the Tyrol with Lombardy. (8) The Brenner Pass, known to the Romans. It also connects the Tyrol with Lombardy; highest point, 4588 feet. It is now crossed by a railway. Two roads lead north from the Rhone valley, and cross the Bernese Alps, over the Grimsel Pass, 6600 feet high, and the Gemmi Pass, 7553 feet high. The roads over the EAST ALPS are much lower, and much more numerous, than those in the MIDDLE or WEST ALPS. The principal are: (1) The road from Venice to Salzburg, crossing the Noric Alps at an elevation of rather more than 5100 feet. (2) The road over the Carnian Alps, which divides into three branches—to Laibach, to the Isonzo, and to the Tagliamento. (3) The roads from the Danube at Linz to Laibach.

Geology.—The rocks which enter into the composition of the Alps belong to many different geological systems, and occur for the most part as more or less interrupted belts or zones, which extend in the same general direction as the great chain itself—viz. from SW. to NE. The higher and central ranges consist principally of crystalline schists, such as gneiss and mica-schist, with which granite is occasionally associated. These crystalline rocks are flanked on either side by an irregular zone of various sedimentary strata, such as clay-slate, greywacke, &c., along with beds of limestone, dolomite, &c., the fossils in which show that this zone contains representatives of the Silurian, Devonian, Carboniferous, and Permian systems. The Triassic strata, occurring in irregular belts on both sides of the great chain, are developed chiefly in the East Alps, where they comprise massive limestones and dolomites of marine origin, remarkable for their fossils, which show a curious commingling of Palæozoic and Mesozoic forms. Liassic strata are poorly developed in the Alps, but they are noted at Schambelen (Aargau, Switzerland) for their abundant and beautifully preserved insect-remains. The Jurassic system is represented on both sides of the Alps, but is developed chiefly in the low grounds of Switzerland, whence it extends into the Jura Mountains. The Cretaceous system appears in like manner on both sides of the Alps, the most prominent feature of the system being its massive 'hippuritic limestones.' The Eocene is represented most prominently by massive 'nummulitic limestones,' and by certain unfossiliferous sandstones and shales (Flysch), which extend along the northern part of the Alps from the SW. of Switzerland to the neighbourhood of Vienna. The Oligocene and Miocene are best developed in Switzerland, where they form some of the better-known mountains at the foot of the Alps, such as the Righi, the Rossberg, &c. They consist chiefly of conglomerates, sandstones, and similar strata. Patches of sands referable to the Pliocene occur here

and there at the base of the Alps in North Italy. The Pleistocene is well represented by a great variety of superficial accumulations, of which the most noteworthy are the ancient moraines, erratics, and perched blocks, fluvio-glacial detritus, and other memorials of the glacial period, together with notable interglacial deposits.

The geological structure of the Alps clearly shows that these mountains are 'mountains of upheaval.' Strange to say, the existing chain occupies the site of very much older mountains which had been elevated towards the close of Palæozoic times, and during a prolonged period had suffered excessive erosion. Subsequently that ancient Alpine land, then greatly reduced, slowly subsided—its more prominent heights enduring for a long period as gradually diminishing islands in the broad Mediterranean of Mesozoic times. The sinking of the land continued, with occasional pauses, throughout the Mesozoic era, so that an immense thickness of sediment eventually accumulated over the slowly subsiding sea-floor. Early in Cainozoic times the ancient Palæozoic Alpine land had been completely submerged, and become buried under many thousand feet of horizontal strata, mostly marine. Late in the Eocene period elevation of the sea-floor supervened, with the result that a broad flat land extended over the site of the present Alps. That crustal movement—one of compression from SE to NW.—continued into late Tertiary times, and the broad flat land of horizontal strata was buckled up into a great series of mountain-ranges. Instead of a low-lying flat land measuring probably 600 to 1200 kilometres across, we have now a lofty chain averaging no more than 150 kilometres in width. The Alps are a conspicuous example of 'folded mountains' (see MOUNTAINS). Not only have the strata been compressed and flexed and convoluted, but enormous rock-sheets, many square miles in extent, have been displaced and driven successively for miles one over another—great masses of Mesozoic strata, for example, derived from the central and southern Alpine area, have invaded the northern area, and come to rest on strata much younger than themselves. The geological succession has in such cases been inverted, and the mountains carved by erosion out of these travelled rock-sheets are said to be 'without roots.' The Matterhorn and other mountains of the Central Alps are examples of the kind, and the Mythen and many mountains in North Switzerland are similarly 'without roots.'

Since their upheaval, the Alps have suffered excessive denudation. Enormous mountain-masses have been gradually removed by the action of ice, running water, &c. It is therefore often extremely difficult to trace any connection between the present configuration and that which must have obtained when the strata were first squeezed into great undulations. In fact, these mountains are not more an evidence and memorial of the stupendous effects produced by earth-movements than they are of the potency of long-continued denudation. One of the most interesting questions connected with the physical geology of the Alps is that of the origin of the remarkable rock-basins which are occupied by the beautiful lakes of Switzerland and North Italy. By some geologists these rock-basins are believed to be due to unequal movements of elevation or depressions, while others have suggested that they may owe their origin to fractures and dislocations. According to the late Sir A. C. Ramsay, on the other hand, they have been excavated by glacial action. Many geologists now maintain that the great depths attained by not a few of the valleys of the Alps are due to glacial erosion. They point out that the relation of the tributary valleys to the main valleys is abnormal. In the long-established river-systems of

a non-glaciated region, lateral or tributary valleys gradually widen and flatten out as they approach the main valley, but in a highly glaciated area like the Alps the tributary valleys are often abruptly truncated by the main valley. Thus the Rhone valley, which, between Visp and Martigny, is broad and deep, with more or less precipitous sides—a gigantic trench, in fact—is joined by numerous tributaries that shoot down through a succession of abrupt, narrow, and profound gorges. Follow one of these upwards for 800 or 1000 feet, and we find ourselves somewhat suddenly in a relatively wide and open valley. Obviously the latter is truncated or cut across by the deep trench of the Rhone—the over-deepening being attributed to the enormous Pleistocene glacier, the erosive action of which must have been concentrated along the medial line of the great ice-flow.

Mineralogy.—Precious stones are abundant among the crystalline rocks of the central ranges, especially in the region of the St Gotthard. The rock-crystal of St Gotthard has a world-wide reputation. Mining and smelting become more and more productive as we advance eastward. Switzerland is poor in useful ores. Gold and silver are found in Tyrol, Salzburg, and Carinthia; there are also silver-mines in Styria and Illyria, and one near Grenoble. Copper is found in the French Alps, in Tyrol, and Styria. There are well-known lead-mines near Villach. The yield of iron in Switzerland, Savoy, and Salzburg is trifling; Carinthia and Styria produce large amounts; and a considerable quantity of quick-silver is extracted at Idria. The region is rich in salt, especially at Hall and Hallein. Coal is found in Switzerland, in Savoy, and in the French Alps, but in no great quantity; the eastern Alps are richer. The mineral springs, hot and cold, are innumerable. See AIX, ISCHL, LEUK, BADEN, &c.

Animals.—The Alpine mountains present many peculiarities worthy of notice in the animal as well as in the vegetable kingdom (see ALPINE PLANTS). On the sunny heights, the number of insects is very great; the butterflies are especially numerous. The great lakes of the Alps have a restricted, but broadly distributed fauna; they are often very rich in fishes, and salmon and trout are sometimes caught in ponds even 6000 feet above the level of the sea. The frog, newt, black salamander, and other amphibia occur at considerable elevations. Although the lofty mountains are inhabited by eagles, hawks, and various species of owls, yet the birds are few in comparison with the numbers in the plains, and those few are mostly confined to the larger valleys. Among the quadrupeds, the ibex or steinbok, a wild goat, is sometimes, though rarely, to be met with; the chamois is more frequently seen, chiefly in the eastern districts. The marmot (*Arctomys marmotta*) inhabits the upper Alpine regions. The Alpine hare (*Lepus variabilis*), which is white in winter, and the snow mouse or vole (*Arvicola nivalis*) may also be mentioned. Wolves are seen more frequently in the west than in the east; in the latter, on the other hand, bears, lynxes, and wild-cats are found, although constantly diminishing in number. The more characteristic Alpine forms are the survivors of a fauna much more widely distributed in the glacial periods. Of the domestic animals, goats and oxen are scattered everywhere in large herds. There are fewer sheep and horses, and these are not of good breeds. Mules and asses are used more frequently in the south than in the north, especially as beasts of burden. Swine and dogs are not common; the latter are used almost solely by the herdsmen, or are kept in the hospices, to assist in searching for the unfortunate wanderers who may be lost in the snow.

Inhabitants.—The population of the Alpine regions is estimated at 6,000,000 to 7,000,000, of whom perhaps one half are Teutonic, and the other half are of French, Italian, Roumansch (Romanic), or Slavonic origin. Seven states share the Alps. The western portion is divided between France and Italy. Switzerland claims the Middle Alps almost exclusively for her own. Bavaria has only a small share, Liechtenstein a smaller. Austria has the largest, but lost much to Yugoslavia and Italy in 1918-19. The wide valleys opening to the east allow the civilisation of the plains to enter easily among the mountains. The value of the minerals, and the fertility of the soil, have permitted mining, manufactures, and agriculture to take firm root, and a flourishing trade has caused large towns to usurp the place of mere Alpine villages. In the Tyrol, the pastoral life of the mountains has long been mixed up with the working of mines of salt or other minerals. The inhabitants of whole valleys are occupied in various branches of industry to a greater extent than in any other district of the Alps, and their sons travel far and near as artisans. The Alpine mountains are rich in singularly beautiful natural scenery, and attract such crowds of visitors that they have been called 'the playground of Europe' (see ALPINE CLIMBING).

See works by Agassiz, Schlegelintweit, Murchison, Tyndall (1860), Conway (1904), Coolidge (1908), and Bonney (1912); also GLACIERS, MOUNTAINS, SWITZERLAND.

Alpujar'ras (Arabic *Al-Busherat*), a name applied to all the valleys lying south of the chief chain of the Sierra Nevada, in the south of Spain.

Alsace-Lorraine (Ger. *Elsass-Lothringen*), till its cession to France in 1919, was a state or 'imperial territory' (*Reichsland*) of the German empire. A naturally rich and historically interesting region, with fertile soil and active industries, it occupies the extreme SW. corner of Germany, and is bounded west by France, east by Baden, and south by Switzerland. Its utmost length from north to south is 123 miles; its breadth varies between 22 and 105 miles; and its area is 5580 sq. m., of which 1353 belong to Upper Alsace (in the south), 1844 to Lower Alsace (NE.), and 2383 to Lorraine (NW.). Pop. (1871) 1,549,738; (1885) 1,564,354, of whom 1,368,711 were natives of Alsace-Lorraine, and 151,753 Germans from other parts of the empire; (1910) 1,874,014, of whom 76 per cent. were Catholics, and more than 87 per cent. spoke German—mainly Alsatian, a dialect of Allemannian. Upper Alsace (Haut-Rhin) had in 1921 468,943 inhabitants, Lower Alsace (Bas-Rhin) 651,686, and Lorraine (Moselle) 589,120—total, 1,709,749. The annexations of 1871 and 1919 were followed by considerable migrations. The French-speaking population is mainly in the larger towns and in Lorraine. The Rhine flows 115 miles north-by-eastward along all the eastern boundary, and receives, below Strasbourg, the Ill from Alsace, 127 miles long. Other rivers are the Moselle, flowing through Lorraine past Metz, and its affluent the Saar. Along the Rhine is a strip of level country, 9 to 17 miles broad, and declining from 800 to 450 feet above sea-level. Westward of this rise the Vosges Mountains, culminating at a height of 4677 feet; whilst Lorraine, rather hilly than mountainous, rarely attains 1300 feet. About 48·5 per cent. of the entire area is arable, 11·6 meadow and pasture, and 30·8 under wood. Alsace-Lorraine produces much wine, grain, and tobacco; it is rich in iron and coal; and manufactures potash, petrol, iron, cotton, wool, silks, chemicals, glass, and paper. It contains the important cities of Strasbourg, Mülhausen, Metz, and Colmar. As a French province (before 1871), Alsace was divided into the

departments of Haut-Rhin and Bas-Rhin. Lorraine fell into the departments of Meuse, Moselle, Meurthe, and Vosges (parts of which remained French). A representative constitution was granted in 1911, the governor (*statthalter*) being supported by a diet of two chambers, the first containing representatives of various interests (religions, chambers of commerce, &c., with nominees of the emperor), the second sixty elected members.

In Cæsar's time Alsace-Lorraine was part of Celtic Gaul, but during the decline of the Roman empire the Alemanni and other Germanic tribes occupied it. From the 10th century it formed part of the German empire, under various sovereign dukes and princes, till a part of it was ceded to France at the peace of Westphalia (1648), and the rest fell a prey to the aggressions of Louis XIV., who seized Strasburg (1681) by surprise in time of peace. By the peace of Ryswick (1697), the cession of the whole was ratified. Thus—as the Germans used to complain—was this fine land, with one of the noblest branches of the race, alienated from the German people, and the command of the German Rhine disgracefully surrendered to the enemy in the time of misfortune. German never ceased to be the chief language of the people, and all newspapers were, during the whole period of the French possession, printed in both languages. In 1814-15 Russia would not hear of the restitution of Alsace-Lorraine to Germany; and it was not till 1871, after the Franco-German war, that Alsace and German Lorraine were, by the treaty of Frankfurt, incorporated in the new German empire. The great mass of the population were strongly against the change, and 160,000 elected to be French, though only 50,000 went into actual exile, refusing to become German subjects. For, at least since the era of the Revolution, Alsace in sentiment was wholly French. To France she gave the bravest of her sons—Kellermann, Kléber, and many another hero. Strasburg first heard the *Marseillaise*; and MM. Erckmann-Chatrian, Lorrainers both, faithfully represented their countrymen's love of *La Patrie* in the days of the second as of the first Napoleon. France, too, was always thinking of her loss, eager some day to repair it; and the imperial territory, for ages the borderland and battlefield of two great powers, remained a perpetual cause of strained relations between France and Germany. Of late it is claimed by the Germans that, through the emigration of the irreconcilables and the immigration of German settlers, the tendency of the older natives to accept the inevitable, and the rising up of a new generation to whom the French connection was a tradition, the situation had changed in favour of Germany and the existing firm but fair administration. The irritating passport system, a special grievance not in force elsewhere in Germany, was withdrawn in 1893. By the treaty of Versailles (1919) the territory was ceded to France, within the boundaries of 1871. See works by Grad (1889) and Matthis (1890), on folklore by Gaidoz and Sebillot (1883), on songs by Weckerlin (1883). For the history of Lorraine, see **LORRRAINE**.

Alsatia, a cant name applied to the precinct of Whitefriars, which, until 1697, enjoyed the privilege of a debtors' sanctuary, and hence was crowded with swindlers and bullies. The name is first met with in 1623. Shadwell's comedy, *The Squire of Alsatia* (1688), is Scott's authority for some of the finest scenes in the *Fortunes of Nigel*.

Alsen, an island in the Baltic, off the coast of Sleswick. Formerly Danish, it became Prussian in 1864, Danish again by plebiscite in 1920. Its greatest length is 19 miles; its greatest breadth 12; and its area is 121 sq. m. Pop. 25,000, almost all

Danish-speaking. The island, one of the finest in the Baltic, has a picturesque appearance, is very fertile, with rich woods, and numerous lakes abounding in fish. The chief town is Sonderborg, with an excellent harbour, and a population of 10,000.

Alster, a river in Holstein, is formed by the confluence of three streams, and, in the neighbourhood of Hamburg, spreads itself out, and forms a lake, called the Great or Outer Alster, and within the town, the Inner Alster. It flows by several canals into the Elbe.

Alstroemeria, or *Alstromer's Lily*, a genus of Amaryllidaceæ (q.v.), cultivated for its flowers and curiously twisted leaves, which have the upper in the normal position of the lower surface. Some have climbing or twining stems; amongst these is the beautiful *salsilla* (*A. salsilla*), a native of Peru, which is cultivated in the West Indies, and its tubers eaten like those of the potato. In Britain, it requires the stove or a hot-bed. *A. ovata*, also a beautiful plant, with a slender twining stem and ovate leaves, is cultivated in Chili for its tubers, which weigh 3 to 6 ounces, and are used as food. A kind of arrowroot is also prepared in Chili from the succulent roots of *A. pallida* and other species.

Altai, the Ghin-shan or Golden Mountains of the Chinese, is the name given to a wild mountainous region which covers the southern parts of Tomsk, in Siberia, and partly extends into Mongolia. It comprises the mountainous border-region of the great plateau of Central Asia, between the Tian-shan and the Sajon Mountains, and consists of two separate parts—the Altai proper, belonging to Siberia; and the Great Altai, in Outer Mongolia. The former covers with its numerous intricate chains and their spurs a surface thrice as large as Switzerland. Although occupied by the Russians since the 17th century, its orography and structure are but imperfectly known. A huge mountain-ridge, the Sailughem, which separates Russia from China, is the border-ridge of the Central Asian plateau; it is continued to the SW. as the high but yet unexplored ridge of West Sajon, which fringes the plateau in the basin of the Yenisei. Its summits reach a height of from 7000 to 9000 feet. It is pierced in the SW. by the deep depression of Lake Zaisan, which gives an easy access to the high plateau of Central Asia. A series of no less than three different chains fringes the Sailughem ridge towards the NW. Some of these chains are snow-clad, and their highest summit, Byelukha, reaches the height of 17,800 feet; while many others seem to reach 14,000 feet. Granites, syenites, and partly also porphyries covered with crystalline slates, as also with Silurian, Devonian, and Carboniferous deposits, constitute the mountains. Deep and wild gorges, immense glaciers, beautiful alpine lakes (the Teletsk, 1600 feet above the sea), and fertile alpine valleys (like the Bukhtarma Valley, 190 miles long), render the Altai a most attractive alpine region. The valleys on its outskirts are being rapidly colonised by Russian agriculturists, who find an easy living in the fertile soil and the rich sub-alpine meadows. The gold-washings of the Altai, and its silver, lead, copper, iron, and coal mines, are another source of wealth. A few Kalmycks, Teleutes, and Kumandintses represent a formerly denser and more civilised population, all of Ural-Altaic stock. Barnaul (34,000 inhabitants) is the chief centre of administration. The Great Altai is a high chain of mountains running from NW. to SE., from Lake Zaisan to the central parts of the Gobi, and bordering the Urumtsi depression. See **ASIA**; and Turner's *Siberia* (1905).

Altamira, in NW. Spain near Santander, is noted for its great cave, adorned with truthful and

spitted Palæolithic paintings in three colours of bison, boar, and other animals. See ANTHROPOLOGY, ARCHAEOLOGY.

Altamur'a, a town of South Italy, 28 miles SW. of Bari, near the base of the Apennines. Its fine cathedral dates from 1220. Pop. 25,000.

Altar (Lat. *altare*, from *altus*, 'high'), the place whereon offerings were laid both by Jews and heathens. The first on record is that which Noah built on leaving the ark. The Israelites, after the giving of the Law, were commanded to make one. Both in the Jewish tabernacle and temple there were two altars, one for sacrifices, and another for incense. The Jewish and oriental altars were generally either square or oblong; those of Greece and Rome, on the other hand, were often round. Sacrifices were offered to the infernal gods, not on altars, but in cavities dug in the ground (see SACRIFICE).

The word has been transferred into the Christian system. For upwards of five centuries, altars in the Christian churches were for the most part made of wood, and an altar of this kind is still to be seen in St John Lateran's at Rome. But the custom of celebrating the liturgical service on the marble sepulchre of the martyrs in the catacombs, led to the introduction of stone altars; and in a council held at Epone in France, 509 A.D., it was decreed that none should be consecrated with chrism except those built of stone. In the Roman Catholic Church, the rubrics require that all altars should be of stone, but the stone itself may be only large enough to hold the host and chalice, and the slab, perhaps no more than a foot square, may rest on, or be inserted in, a board of wood. Such a stone may with license be used as a 'portable altar' by priests requiring to say mass on a journey or in private houses. The stone must in all cases be provided with relics inclosed within it, and be consecrated by a bishop. The altar must be covered with three cloths, one of which must reach to the ground. It should also, if possible, have attached to it in front a 'pallium,' or frontal, varying in

High Altar:
Church of the Sacred Heart, Edinburgh.

colour according to the feast or season. The essentials of the altar for mass in Roman Catholic churches are the altar itself, the altar cloths, the missal, the three cards (containing portions of the missal), the tabernacle for the reservation of the host, and the crucifix. In the throne above the tabernacle, the host is occasionally exposed in a vessel called the Monstrance (q.v.), as at the service of the 'Benediction;' the crucifix being

removed. The crucifix must stand upon or above the altar, between two candles. The missal is moved from side to side of the altar at various parts of the mass. The epistle is read from the right side, and the gospel from the left; hence it is customary to speak of the epistle and gospel sides of the altar. The Credence Table (q.v.) and the Piscina (q.v.) are adjuncts of an altar.

In the first ages of Christianity, there was only one altar in a church; but, from a very early time, the Latins have used more than one. The principal altar is called the high altar. In the 12th century, the adorning of churches with numerous altars was carried to a great extent, and they were embellished with gold, silver, and precious stones. The Greek Church use but one altar. Altars were frequently placed at the west end of the ancient churches (as in the old British Church), instead of the east. The only perfect altar of the old times in England is the high altar of Arundel church, Sussex. The slab is 12 feet 6 inches long, by 4 feet wide, and 2½ inches thick; the support is of solid stone, quite plain. For 300 years after the time of Christ, the word altar was constantly used to describe the table of the Lord; subsequently 'table' and 'altar' were used indifferently. In the first Prayer-book of King Edward (1549), the word altar was used in the rubric, and the Lord's Supper was still called the Mass; but in 1550, an order was issued for the setting up of tables instead of altars, and in the second Prayer-book of 1552, the word 'altar' was everywhere superseded by 'table;' though 'altar' is retained throughout the coronation service. The table was further ordered to be of wood, and movable. In Mary's reign the altars were re-erected; but in Queen Elizabeth's, some were riotously pulled down, and injunctions were then issued directing that this should not be done, except under the oversight of the curate and at least one churchwarden. It was charged against Archbishop Laud that he had converted communion-tables into altars. What he really did was to remove the tables out of the body of the church, and place them 'altarwise'—i.e. north and south, at the upper end of the chancels, where the altars formerly stood; and a dog having on one occasion run away with a piece of the consecrated bread, he directed that rails should be erected to prevent such desecration in future. By the judgment in the Arches Court, 1845, in the case of *Faulkner v. Litchfield*, it was decided that altars may not be erected in churches. This case arose out of the erection, by the Cambridge Camden Society, of a stone altar in the Church of the Holy Sepulchre in that town; but it may be questioned whether this judgment has not been virtually modified by the subsequent action of the English Church, and the indirect effect of the judgments of the same court, and of the privy council in the case of *Sheppard v. Bennet* in 1870-1.

Bowing towards the altar is an ancient practice of the church, a mark of homage offered to the seat of the presence of Christ in Holy Communion. Among Roman Catholics, it is the custom to genuflect before the altar when the host is reserved in the Tabernacle (q.v.).

The doctrine of Sacrifice is fully discussed under that head. See LIGHTS (USE OF), BALDACHIN, RITUALISM.

Altazimuth (a contraction for *altitude and azimuth instrument*), an astronomical instrument for determining the apparent places of the heavenly bodies on the celestial sphere. It consists of a telescope revolving about a horizontal axis, which in turn revolves about another vertical axis, the angle of revolution being measured in each case by a divided circle. These angles give the Altitude (q.v.) and Azimuth (q.v.) of the heavenly body

observed at the instant of observation, and so indicate its place. Small instruments of this kind are used in surveys. The principal one in existence is that at Greenwich, designed by Sir George Airy, the object of which was to supplement the lunar observations taken on the meridian by the Transit Instrument (q.v.) by others taken when the moon was in other parts of the sky. Its two chief principles of structure are, that as many parts as possible are cast in one piece, and that no power of adjustment is provided anywhere; the errors of construction and original adjustment being allowed for in the reduction of the observations. By means of this instrument much has been gained in knowledge of the moon's places, the observations made with it, owing to its freedom of pointing to any part of the heavens, exceeding in number those obtained by the fixed meridional instruments in the proportion of 16 to 9. The altazimuth is not, however, in general use, owing to its liability to many errors, unless, as at Greenwich, most carefully and solidly designed and constructed.

Altdorf. See ALTORF.

Altdorfer, ALBRECHT (1480?-1538), painter, engraver, and architect, was born at Ratisbon, and may have been a pupil of Dürer; at any rate, he belongs to that religious school of artists of which Dürer was the head. His pictures are animated by a romantic and poetic spirit; and the landscape is delineated with the same truth and tenderness as the figures. His masterpiece, now in Munich, is 'Alexander's Victory over Darius.' As engraver, Altdorfer is reckoned among the 'Little Masters.' See Sturge Moore, *Altdorfer* (1900).

Alte'a, a Spanish seaport, 25 miles NE of Alicante. The harbour is good. Pop. 6000.

Alten, KARL AUGUST, COUNT OF, Hanoverian general, born in 1764, entered the army in 1781, but in 1803 left Hanover for England, where he was made commander in the German Legion. In almost all the engagements of the Spanish war of liberation he took a prominent part; and he fought with distinction at Quatre-Bras and Waterloo. After his return to Hanover, he was made minister of war. He died April 20, 1840.

Altena, a town of Prussia, in the district of Arnsberg, 47 miles NW. of Siegen by rail, in a deep and picturesque valley. It manufactures needles, pins, and hardware. Pop. 15,000.

Altenburg, a town of Thuringia, capital of the former state of Saxe-Altenburg, on the Pleisse, 30 miles S. of Leipzig, has a famous old castle on a steep rock of porphyry. Hence in 1455 a neighbouring knight, Kunz von Kaufungen, carried off two young Saxon princes (the 'Prinzenraub'); but before he could reach the Bohemian frontier, he was apprehended by a charcoal-burner, and handed over to the executioner. Pop. 40,000.

Altendorf, a group of manufacturing villages incorporated with Essen (q.v.). Krupp has iron-works here, and there are manufactures of coke, brick, and cement.

Altenessen, a town 2 miles N. of Essen (q.v.), of which it is now part, with coal-mines and machine-works.

Altengaard, a hamlet in Finmarken, the northernmost province of Norway, situated on the south side of the Alten Fiord, in 69° 55' N. lat. Beyond this point, no cultivation is attempted; and even here, potatoes and barley alone are produced. There is here a meteorological and magnetic station.

Altenstein, KARL, BARON VON STEIN ZUM, a Prussian statesman, born at Ansbach, October 7, 1770. In 1808 he became the head of the depart-

ment of finance, and in 1817 was made minister of public worship and education. He had much to do with founding the universities of Berlin and Bonn. He died at Berlin, May 14, 1840.

Alteratives, in Medicine, a term applied to remedies that 'improve the nutrition of the body without exerting any very perceptible action on individual organs' (Lauder Brunton). This group includes a number of substances of the most diverse characters and properties, having this only in common, that their mode of action is obscure, though its results are often of the greatest value. In fact 'we use the word alteratives very much as a cloak for our ignorance.' It has been suggested, that alteratives act either by modifying the action of the ferments in the body, or by replacing the normal constituents of the tissues by others with different properties. Among the most important alteratives are various preparations of arsenic, mercury, iodine, phosphorus, gold; cod-liver oil, colchicum, guaiacum, sarsaparilla. Many of them are violent poisons when taken in improper doses. As examples of their action, may be cited the beneficial effect of mercury and iodides in the various morbid processes of syphilis; of cod-liver oil and iodides in tuberculous diseases; of arsenic in inflammations of the skin.

Alternation. See GENERATIONS (ALTERNATION OF).

Althæa. See MARSH MALLOW, HOLLYHOCK, MALVACEÆ.

Althorn. See SAXHORN.

Althorp. See SPENCER.

Altitude, in Astronomy, is the height of a heavenly body above the horizon. It is measured, not by linear distance, but by the angle which a line drawn from the eye to the heavenly body makes with the plane of the horizon, or by the arc of a vertical circle intercepted between the body and the horizon. Altitudes are taken in observatories by means of a telescope attached to a graduated circle (see CIRCLE), which is fixed vertically. The telescope being directed towards the body to be observed, the angle which it makes with the horizon is read on the graduated circle. The altitude thus observed must receive various corrections—the chief being for Parallax (q.v.) and Refraction (q.v.)—in order to get the true altitude. At sea, the altitude is taken by means of a Sextant (q.v.), and then it has further to be corrected for the dip of the visible horizon below the true horizon (see HORIZON). The correct determination of altitudes is of great importance in most of the problems of astronomy and navigation (see LATITUDE and LONGITUDE).—An ALTITUDE AND AZIMUTH INSTRUMENT, called by contraction ALTAZIMUTH (q.v.), consists essentially of a vertical circle with its telescope so arranged as to be capable of being turned round horizontally to any point of the compass. See AZIMUTH.

Alto, in Music, is properly the same as Counter Tenor (q.v.), the male voice of the highest pitch (now principally falsetto), and *not* the lowest female voice, which is properly contralto, though in printed music the second part in a quartet is always entitled *alto*. See CONTRALTO.

Alton, a town of Hampshire, 8½ miles SW. of Farnham. Its Perpendicular parish church was thoroughly restored in 1867. Hops are grown in the neighbourhood, and there are large breweries in the town. Pop. 5600.

Alton, a city and port of entry of Illinois, U.S., on the left bank of the Mississippi River, 24 miles N. of St Louis, and 8 miles above the mouth of the Missouri. Laid out in 1817, and since 1868 the seat of a Catholic bishopric, it is a centre of

commerce, and has a Baptist college (1836), several mills and manufactories, and an abundant supply of limestone. Pop. 25,000.

Altona, the largest and richest city in the Prussian province of Sleswick-Holstein, is situated on the steep right bank of the Elbe, just below Hamburg, so that the two cities are divided only by the state boundaries. Altona lies higher than Hamburg, and is much healthier; but, in a commercial point of view, the two may be almost regarded as forming a single city. The trade is largely with America. There are many important industrial establishments in Altona, such as cotton and woollen mills, tobacco and soap factories. The celebrated observatory, founded by Schumacher in 1823, was transferred to Kiel in 1874. Of public buildings, the most notable are the churches of the Trinity (1743) and St John (1873); and of monuments, one to the governor, Von Blucher (1832). Invested by the Danish king with special privileges in 1664, as rival to Hamburg, and burnt by the Swedes in 1713, Altona was annexed to Prussia in 1866. Its population and area have increased rapidly—(1840) 28,095; (1860) 45,524; (1885) 104,719; (1890) 143,249; (1910) 172,628; (1919) 168,729.

Altoona, a city of Pennsylvania, U.S., at the eastern base of the Alleghenies, 117 miles E. of Pittsburgh. It contains large locomotive-works and machine-shops in connection with the Pennsylvania Railroad. Near Altoona is a remarkable triumph of railway engineering, known as the 'Horseshoe Bend.' Pop. (1870) 10,610; (1900) 38,973; (1910) 52,127; (1920) 60,331.

Altorf, or **ALTDORF**, the chief town in the Swiss canton Uri, is situated in a sheltered spot at the base of the Grunberg, at the head of the Lake of Lucerne. The little tower on which the legendary exploits of William Tell are painted in rude frescoes is of dubious antiquity. Situated on the St Gothard road and railway, Altorf has some transit trade. Pop. about 3000.—The old town of **ALTOERF**, or **ALTDORF**, in Middle Franconia (pop. 4000), was the seat of a university from 1623 to 1809.

Alto-rilievo (Ital., 'high relief'), in Sculpture, used of figures projecting from the background on which they are carved, by at least half their thickness; so called as distinguished from *basso-rilievo* ('low relief'), and *mezzo-rilievo* (see RELIEF, SCULPTURE). The Elgin Marbles (q.v.) comprise the most notable high reliefs.

Altötting, a very ancient place of pilgrimage in Upper Bavaria, not far from the river Inn. The chapel, said to have been built on the site of a heathen temple, contains the famous black image of the Virgin Mary, dating from the 8th century, and an extraordinarily rich treasure of gold, silver, and precious stones. Another chapel contains the tomb of Tilly. Pop. 5300.

Al'trincham, an urban district of Cheshire, England, on Bowdon Downs, 8 miles SW. of Manchester by rail, is situated on the Bridgewater Canal. Its mayor is appointed annually, under an old charter, by the lord of the manor; but he has no jurisdiction, his chief duties being to open fairs and administer some funds left to the town three centuries ago. It is a very neat and clean town, and on account of the salubrity of the air, is much resorted to by invalids from Manchester. It has manufactures of artificial manures, and an iron-foundry; but a chief employment of its inhabitants is the raising of fruits and vegetables for the market of Manchester. Pop. (1851) 4488; (1871) 8478; (1911) 17,813; (1921) 20,461.

Altruism is the English form of the Fr. *altruisme*, a word formed by Comte from the Ital. *altru*, 'of or to others;' and, introduced

into English by the translators and followers of Comte, has gradually come into more general use. It is opposed to egoism or selfishness, and means unselfishness or devotion to the welfare of others as a principle of action or an element of character. See ETHICS, UTILITARIANISM, &c.

Alum, a white, saline substance, with a sweetish, astringent taste, is, properly speaking, a double salt, being composed of sulphate of potash and sulphate of alumina, which, uniting together along with a certain proportion of water, crystallise in octahedrons or in cubes. Its formula is $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$. Alum is soluble in eighteen times its weight of cold water, and in its own weight of hot water. The solution thus obtained is strongly acid to coloured test-papers. When heated, the crystals melt in their water of crystallisation; and when the water is completely driven off by heat, there is left a spongy white mass, called *burnt alum* or anhydrous alum. Alum is much used as a mordant in dyeing. This property it owes to the alumina in it, which has a strong attraction for textile tissues, and also for colouring matters; the alumina thus becomes the means of fixing the colour in the cloth. The manufacture of the colours or paints called lakes depends on this property of alumina to attach to itself certain colouring matters. Thus, if a solution of alum is coloured with cochineal or madder, and ammonia or carbonate of soda is added, the alumina of the alum is precipitated with the colour attached to it, and the liquid is left colourless. Alumina, the basis of pure clay—which is a silicate of alumina—derives its name from being first extracted from alum. Alum is also used in the preparation of leather from skins, and, in medicine, as a powerful astringent for arresting bleeding and mucous discharges. Its use to impart whiteness to bread made from poor flour is highly objectionable.

Alum rarely occurs in nature, except in a few springs and in some extinct volcanoes, where it appears to be formed from the action of sulphurous acid vapours upon felspathic rocks. In this country it is prepared artificially from alum-shale, obtained from coal-mines at Hurler and Campsie, near Glasgow; and from alum-slate, which occurs at Whitby, in Yorkshire. The alum-slate, shale, or schist consists mainly of clay (silicate of alumina), iron pyrites (bisulphuret of iron), and coaly or bituminous matter. When the shale is exposed to the air—as it is in the old *coal-wastes* or mines from which the coal has been extracted—the oxygen of the air, assisted by moisture, effects a decided change upon it. The original hard stony substance begins to split up into thin leaves, and becomes studded over and interspersed with crystals. The latter are the result of the oxidation of the sulphur of the pyrites into sulphuric acid, and the iron into oxide of iron, both of which in part combine to form sulphate of iron, whilst the excess of the sulphuric acid unites with the alumina of the clay, and produces sulphate of alumina. When the alum-shale thus weathered is digested in water, there dissolve out the sulphate of alumina, $Al_2(SO_4)_3$, and sulphate of iron, $FeSO_4$; this solution is treated with chloride of potassium, KCl, which decomposes the sulphate of iron, forming sulphate of potash, K_2SO_4 , and dichloride of iron, $FeCl_2$. When this liquid is evaporated to concentration, and allowed to cool, crystals of alum, leaving the composition above described, separate out, and the protochloride of iron is left in the solution or *mother-liquor*. The crystals of alum obtained from the first crystallisation are not free from iron, and hence require to be redissolved in water, re-concentrated, and recrystallised. This operation is generally repeated a third time before the alum is obtained pure.—As the preliminary weathering of the shale takes some years

to complete, a more expeditious method is now largely resorted to. The shale is broken in fragments, and piled up over brushwood in long ridges shaped like huge potato-pits, and the brushwood being set fire to, the coaly matter of the shale begins to burn, and the whole ridge undergoes the process of roasting; the results of which are the same as that of the weathering operation—namely, the oxidation of the sulphur and iron, and the formation of sulphate of alumina and sulphate of iron. This material is afterwards worked up as previously described. The roasting operation is so much more expeditious than the weathering process, that months suffice instead of years. Alum is also largely manufactured from its constituents by direct combination. Clays are calcined as pure as possible from iron and calcium carbonate, and dissolved in dilute sulphuric acid. The aluminium sulphate formed is crystallised into alum by the addition of potassium sulphate. It is made near Edinburgh in this way, from the ashes of coal. The alum made at Tolfa, near Civita Vecchia, is extracted from alum-stone, a mineral containing sulphate of potash and sulphate of alumina, but united in such a form as to render them insoluble. When the mineral is calcined, the sulphates become soluble, and are extracted by lixiviation. The alum thus manufactured (*Roman alum*) crystallises in opaque cubes, having a reddish tint, due to the presence of iron. The potash in alum can be replaced partly or altogether by soda or ammonia; and other replacements can also be made. Thus there are soda, ammonia, chrome, iron, &c. alums. The more important members of the class are:

$K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$, potash alum.

$Na_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$, soda alum.

$(NH_4)_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$, ammonia alum.

Alum-Bagh (*Alambagh*), a fort rendered famous during the Indian mutiny in 1857. It was a domain about 4 miles from the city of Lucknow, and comprised a palace, a mosque, and a park; and was converted by the rebels into a fort. It was taken by the British forces in September; and on evacuating Lucknow, Sir Colin Campbell left Sir James Outram with 3500 men to hold the Alum-Bagh. He was surrounded by the insurgent forces of 30,000 sepoys and 50,000 volunteers, and was repeatedly attacked by them, but in vain. In March, Sir Colin Campbell reconquered Lucknow, and relieved the Alum-Bagh from its perilous isolation. Havelock had been buried within the walls in November 1857.

Alumina, the most abundant of the Earths (q.v.), is the oxide of the metal Aluminium (q.v.), the formula being Al_2O_3 . It occurs in nature abundantly in combination with silica, associated with other bases. The most familiar of its native compounds is felspar, a silicate of alumina and potash, $K_2O \cdot Al_2O_3 \cdot (SiO_2)_2$. This is one of the constituents of granite, and of several other igneous rocks. Certain varieties of these, by exposure to the atmosphere, become completely disintegrated, passing from the state of hard, solid rock, such as we are accustomed to see in building-granite, into soft, crumbling, earthy masses. It is the felspar which undergoes the change; and it appears to be owing to the action of rain-water charged with carbonic acid, which dissolves the potash and some of the silica of the felspar, leaving the excess of silica and the alumina still united. It is not known, however, why certain specimens of granite are rapidly corroded and crumbled down, whilst others have resisted for ages the same causes of decay. By such a process of disintegration as we have described, the clays of our arable soils are produced. Clay consists of silica and alumina in a state of

chemical combination. It never is pure alumina, but the quantity of silica united to the latter is variable. When it is pure, clay is quite white, as we see in the porcelain clay of Devonshire and Cornwall, which is derived from colourless felspar. More frequently, clay is red, owing to the presence of oxide of iron; or black, from the diffusion through it of vegetable matter.

From alum, alumina is prepared by adding to a solution of the former, water of ammonia, as long as it occasions a precipitate. The alumina appears as a voluminous, white, gelatinous substance, consisting of the oxide of the metal combined with water. When alumina is precipitated from a solution containing colouring matter, such as logwood, &c., it carries down the colour chemically united to the flocculent precipitate; in this way are formed the coloured earths called *Lakes* (q.v.). Alumina in the state of precipitate, after being gently dried, is readily soluble in acids and in alkalies; but if strongly heated, at a certain temperature it presents an appearance of sudden incandescence, it loses the associated water, contracts greatly in bulk, and now forms a white, soft powder, not at all gritty, and with difficulty soluble in alkalies and acids. Alumina, as generally prepared, whether hydrated or anhydrous, is insoluble in water, possesses no taste, and does not alter colouring matters; but it has also been obtained in an allotropic hydrated form, which, in the presence of a very small proportion of acetic acid, is largely soluble in water, from which a minute trace of sulphuric acid precipitates it. It is quite different, therefore, in properties from the alkaline earths, and is a much weaker base. In the anhydrous state it absorbs water with great readiness without combining with it, so that it adheres to the tongue, and is felt to parch it. Clay retains this property; and the ends of tobacco-pipes are often glazed, to prevent adhesion to the lips or tongue. Alumina is not fusible by a forge or furnace heat, but it melts before the oxyhydrogen blow-pipe into a clear globule, possessing great hardness. It occurs in nature in a similar state as Corundum (q.v.). The more coarsely crystallised specimens form the emery used for polishing; the transparent crystals, coloured by a trace of metallic oxide, constitute the precious gems sapphire, ruby, oriental amethyst, and oriental topaz. Alumina, like other sesquioxides, is a feeble base.

Aluminium—sym. Al, eq. 27—is one of the metals present in clay, felspar, slate, and many more rocks and minerals. It was named about 1812 by Davy, who dissolved alumina, but failed to isolate the metal. It was isolated by Wöhler in 1828, and was re-examined by him in 1846, when he obtained the metal in minute globules or beads, by heating a mixture of chloride of aluminium and sodium. In 1855, the French chemist Deville showed, as the result of a series of experiments, that aluminium could be prepared on a large scale and in a compact form without much difficulty. The mineral cryolite found in Greenland, which is a double fluoride of aluminium and sodium, was the ore first used for its manufacture; but bauxite, a clay first found at Les Baux, near Arles, consisting chiefly of alumina or oxide of aluminium, and oxide of iron, has since been employed as a more convenient source of the metal. An aluminate of soda is first obtained by heating the bauxite with soda ash in a furnace, and separating it (the aluminate) from the insoluble portions by lixiviation. When carbonic acid is passed through the solution, pure alumina is thrown down. The alumina is then formed into balls with common salt and charcoal, which are heated in an earthenware retort through which chlorine gas is passed. In this part of the process,

the charcoal combines with the oxygen, and the chlorine with the aluminium; the latter sublimes over with the common salt (chloride of sodium), and is collected as a double chloride of aluminium and sodium. When this double chloride is heated in a reverberatory furnace with fluxes and metallic sodium, the latter seizes the chlorine combined with the aluminium, which is then set free, and falls to the bottom ready to be cast into ingots for use. Aluminium has also been made from alum. In the Cowles apparatus a mixture of clay (such as bauxite) and charcoal is subjected to the heat of the electric arc and the alumina reduced. As far back as 1854 Bunsen accomplished the manufacture by a somewhat troublesome and expensive electrolysis. But since 1890 electrolytic methods have largely superseded the chemical processes. Hall and Heroult introduced the method of fusing cryolite by an electric current, and adding powdered alumina, which is electrolysed. Advantage is largely taken of the electricity generated by means of waterfalls—as at Neuhausen, near the Schaffhausen falls of the Rhine, and in Norway. The Niagara Falls are employed in the same way; and bauxite from the north of Ireland is the material worked on at the aluminium-works below the Falls of Foyes. Other methods treat kaolin or labrador stone with an acid, and precipitate the metal from the salt thus formed by ammonia or by a suitable temperature.

The properties of aluminium are, that it is a white metal, somewhat resembling silver, but possessing a bluish hue, which reminds one of zinc. This bluish colour can be whitened by hydrofluoric and phosphoric acids, and also by a heated solution of potash. It is very malleable and ductile, in tenacity it approaches iron, and it takes a high polish. It fuses at about 1292° F. (700 C.), and can then be cast in moulds into ingots. Exposed to dry or moist air, it is unalterable, and does not oxidise or tarnish like most common metals. Neither cold nor hot water has any action upon it. Sulphuretted hydrogen, the gas which so readily tarnishes the silver in households, does not act on aluminium, which is found to preserve its appearance under all ordinary circumstances as perfectly as gold does. When cast into moulds, it is a soft metal like pure silver, and has a density of 2.56; but when hammered or rolled, it becomes as hard as iron, and its density increases to 2.87. It is therefore a very light metal, being lighter than glass, and only one-fourth as heavy as silver. Aluminium is very sonorous, a bar of it when struck giving out a very sweet clear ringing sound. It is a good conductor of heat and electricity.

Notwithstanding its many valuable properties, it was for long little in demand. From about 1850 many articles were made, but failed to take the market. It is used for optical, surgical, electrical, and chemical instruments and apparatus. Aluminium leaf and wire may be employed with great advantage in place of silver leaf for decoration, or silver wire for embroidery. Of late it has come to be used in shipbuilding, especially for torpedo-boats, and boats meant to be sent in pieces to African lakes, &c.; for making airships and aeroplanes; for bicycles; and in general for machinery and structures in which the hardness and lightness and non-corrosiveness of aluminium and its alloys are in its favour. And as it is specially suitable for cooking-vessels, efforts to cast it for pots and pans were often made, but unsuccessfully till 1895, when aluminium was, weight for weight, three times the price of copper, but, bulk for bulk, the cheaper metal. It is used in lithography and in welding; and the high explosive ammonal makes use of the great heat of its combustion.

Aluminium Alloys.—Aluminium forms, with

copper, several light, very hard, white alloys; also a yellow alloy, which, though much lighter than gold, is very similar to it in colour. This gold-like alloy, which is ordinary aluminium bronze, contains from 5 to 10 per cent. of aluminium, and is very strong, was discovered by Dr Percy of London. For many years it has been manufactured into watch chains, pencil-cases, and other small ornamental articles. More lately it has been made on a limited scale into such articles as table-plate and carriage mountings, which have an attractive appearance. This bronze, which can be made with a tensile strength equal to steel, has certain advantages for field-guns. Its anti-friction and wearing qualities make it well adapted for bearings of shafts; but its price, considerably in excess of ordinary bronze, somewhat hinders its use on a large scale for objects of utility.

An alloy of aluminium and tin is used for optical instruments, and from another of aluminium and silver called 'Tiers Argent,' excellent spoons and forks are made. Magnesium alloys of aluminium such as magnalium are valuable for hardness and strength.

Alum Root. This name is given in the United States to two plants, natives of that country, very different from one another, but agreeing in the remarkable astringency of their roots, which are medicinally used. One of these plants is *Geranium maculatum* (see GERANIUM). The root contains more tannin than Kino (q.v.) does. The property of astringency belongs, in an inferior degree, to some other species of Geranium, and of the kindred genera, Erodium and Pelargonium.—The other American plant to which the name alum root is given is *Heuchera americana*, a plant of the natural order Saxifragaceæ (q.v.), an order in which also astringency is a prevalent property. The root is a powerful styptic, and is used to form a wash for wounds and obstinate ulcers.

Alunno, NICCOLO, or Niccolo of Foligno, one of the earliest of the old Umbrian painters, was born at Foligno about 1430. His early works were all frescoes, and his subjects were mainly religious. Alunno is not so remarkable for the fertility of his invention as for his warmth of feeling, purity, and devout faith; and may be accounted a worthy predecessor of Perugino.

Alured, or ALFRED, of Beverley, in Yorkshire, an old English historian of the time of Henry I. Little is known regarding him, save that he was treasurer and sacrist of the church of Beverley, where he wrote his *Annales*, in nine books. This work commences with the fabulous period of British history, and extends down to the year 1129. It is a mere rechauffé of Geoffrey of Monmouth, Bede, and Henry of Huntingdon. Written apparently about 1143, it was published at Oxford in 1716 by Thomas Hearne.

Alva, a police burgh in Clackmannanshire (in a district accounted till 1891 a detached part of Stirlingshire), at the base of the Ochils, 7½ miles ENE. of Stirling by rail, is a place of great industrial activity, having extensive woollen-factories, in which the manufacture of shawls and tweeds has superseded that of blankets. To the east of the village is the Silver Glen, where two pits still mark the site of old silver-mines, opened about 1712. Immediately behind the village is Alva Glen, noted for its picturesque beauty and magnificent waterfall. Pop. 4000.

Alva, or ALBA, FERDINAND ALVAREZ DE TOLEDO, DUKE OF, prime minister and general of the Spanish armies under Charles V. and Philip II., was born in 1508, of one of the most illustrious families of Spain. He entered the army a mere youth, and gave such proofs of his courage and

capacity for command in the battle of Pavia (1525), in Hungary in battles against the Turks, in Charles V.'s expedition to Tunis and Algiers, and in Provence, that he rose quickly from rank to rank, becoming general at twenty-six, and commander-in-chief at thirty years of age. His skilful defence of Navarre and Catalonia gained him his rank as Duke of Alva. In 1547 he contributed greatly to the victory which Charles V. gained at Muhlberg over John Frederick, Elector of Saxony. Under his influence, as president of the council of war, the captive elector was condemned to death; and it was entirely against his wish that the emperor commuted the sentence. He took part under the emperor in the unsuccessful expedition against Henry II., king of France, who had taken possession of Metz; but was more fortunate in his next campaign (in 1555) in Italy, against the combined armies of the pope and the French king. After the abdication of Charles V. in 1556, Alva continued to hold the command of the army, and overran the States of the Church, but was obliged by the command of Philip II. to conclude a peace with Pope Paul IV., and restore all his conquests. Being recalled from Italy, he appeared in 1559 at the court of France, and as proxy for his sovereign espoused Elizabeth, Henry II.'s daughter.

When the inhabitants of the Netherlands, who had been accustomed to freedom, revolted against the tyranny of Spain, and especially against the hated Inquisition, the Duke of Alva's counsel was to suppress the insurrection with rigour. The king accordingly sent him to the Netherlands in 1567, with unlimited power and a large military force. His first step on arriving was to establish what was called the 'Bloody Council,' in which he himself at first presided, and over which he afterwards appointed the sanguinary Don Juan de Vargas. This tribunal condemned all without distinction whose opinions appeared dubious, or whose wealth excited jealousy. The present and the absent, the living and the dead, were subjected alike to trial, and their property confiscated by the council. As many as 100,000 abandoned their native country, many of them industrious artisans, mechanics, and merchants, who emigrated to England, while many others enlisted under the banners of the proscribed princes, Louis and William of Orange. Alva, rendered still more savage by a defeat which befell his lieutenant, the Duke of Aremberg, sent Counts Egmont and Horn to the block. He afterwards defeated Prince Louis, and compelled William of Orange to retire to Germany; upon which he entered Brussels in the greatest triumph on the 22d December 1568. The pope presented him with a consecrated hat and sword, as Defender of the Catholic faith; an honour which, having been hitherto conferred only on crowned heads, increased his insolence to the highest degree. His executioners shed more blood than his soldiers; and none now withstood his arms except Holland and Zealand. But these provinces continually renewed their efforts against him, and succeeded in destroying the fleet which had been equipped by his orders. Recalled by his own desire in 1573, he resigned the command of the troops to the mild Don Louis de Requesens, and left the country, in which, as he himself boasted, he had executed 18,000 men. The war which he had kindled burned for nearly seventy years, and cost Spain untold treasure, her finest troops, and the loss of seven of the richest provinces of the Netherlands.

Alva soon lost the royal favour for sheltering his son from the consequences of a misdemeanour, and retired to his castle, till, in 1580, he was recalled to a command in the war against Portugal, the crown of which Philip claimed as his hereditary

right. He quickly drove out Don Antonio, who, as grandson of John III., had taken possession of the throne, and overran the whole country with his accustomed cruelty and rapacity; he seized the treasures of the capital himself, while he allowed the soldiers to plunder without mercy the suburbs and the surrounding country. Philip, dissatisfied with these proceedings, desired to have an investigation of the conduct of the duke; but the haughty bearing of the latter, and the fear of a revolt, induced him to abandon it. Shortly after, Alva died at Thomar, 12th January 1582, at the age of 74. He had a haughty carriage, a hard voice, and a dark and gloomy countenance. He was cruel, avaricious, and a fanatical bigot. It has been said of him, that during sixty years of military service he never lost a battle, and never allowed himself to be surprised. See Motley's *Dutch Republic* (1856).

Alvara'do, a town of Mexico, on the Gulf of Mexico, at the mouth of the river Alvarado, 40 miles SE. of Vera Cruz. Pop. 6000.

Alvarado, PEDRO DE, a famous comrade of Cortes, was born at Badajoz, towards the close of the 15th century. In 1518 he sailed for the New World, and accompanied Grijalva in his exploring voyage along the shores of the American continent. It was now that the Spaniards heard for the first time of the riches of Montezuma, and of his vast empire. Alvarado was soon sent back to Cuba to inform the governor Velasquez of the result of the expedition. In February 1519 he sailed with Cortes and his little band of heroes from Havana, and took an active part in all the incidents of the conquest of Mexico. He held the city of Mexico during the absence of his chief, and massacred in the midst of a fête a great number of disaffected Aztec nobles. In the famous night-retreat of 1st July 1520 (*la noche triste*), Alvarado commanded the rear-guard, and covered himself with glory by his reckless courage. After the conquest of Mexico he subdued, with a small force, the tribes on the coast of the Pacific in the direction of Guatemala. On his return to Spain, the Emperor Charles V. gave him a splendid reception, and appointed him governor of Guatemala. Numerous adventurers followed him to the New World, and Alvarado soon embarked on the Pacific a force of five hundred soldiers for the capture of Quito. He landed near Cape San Francisco, whence he penetrated into the heart of the country, crossing the Andes by a daring march. In the interior he was met by some of the troops of Pizarro, headed by Almagro; but, chivalrously disclaiming any intention to interfere with his countryman's rights, he agreed to retire, on receiving an indemnity for his arduous undertaking. On his next visit to Spain, he cleared himself from the misrepresentations of Pizarro with such success that he received the government of Honduras in addition to Guatemala. Again he embarked for the New World, and pursued his course of discovery and conquest; but, having landed on the Mexican coast to aid the Spaniards in punishing a revolt of the Chichimecas of New Galicia, met his death through accident in 1541.

Alvarez, DON JOSÉ, the greatest of modern Spanish sculptors, was born in 1768, in the province of Cordova. During youth he laboured with his father, a stone-mason; and when twenty years old, began to study drawing and sculpture in the academy at Granada. He secured the patronage of the Bishop of Cordova, and in 1794 was received into the academy of San Fernando, where in 1799 he gained the first prize and a grant to enable him to study at Paris and Rome. In Rome, where he lived on terms of friendship with Canova and Thorvaldsen, he executed a famous group, now in the Royal Museum of Madrid,

representing a scene in the defence of Saragossa. At Rome till 1826, he died at Madrid in 1827.

Alwar, or **ULWAR**, a Rajput state of India, with an area of 3200 sq. m., and a pop. of 800,000. The capital, Alwar, is a town of 40,000 inhabitants, 94 miles WNW. of Agra.

Alyscamps, or **ALISCANS** (equivalent to *Champs Élysées*), a suburb of Arles (q.v.).

Amadavat. See **WEAVER-BIRD**.

Amadeus (i.e. 'Love-God'), a common name in the House of Savoy. The first who bore it was Count Amadeus, who lived in the 11th century; but the first to make an important figure in history was AMADEUS V. (1249-1323).—**AMADEUS VIII.**, born in 1383, secured the elevation of Savoy into a duchy (1416), and in 1418 Piedmont chose him for its ruler; but in 1434 he retired to a hermitage on the shores of the Lake of Geneva. He was elected pope in 1439, when he assumed the name of Felix V.; but he resigned the papal chair in 1449, and died two years afterwards at Geneva.—**AMADEUS I.** of Spain, born in 1845, the second son of King Victor-Emmanuel of Italy, was elected king of Spain in 1870, but, owing to the want of popular sympathy with his government, he abdicated the throne in February 1873, and, as Duke of Aosta, returned to Italy. Died 18th Jan. 1890.

Amadis, a much-used name in the chivalric poetry of the middle ages. Of the many romances (see **ROMANCE**) that may be grouped under it, that which narrates the adventures of Amadis of Gaul is at once the most ancient and the best. It is believed that the earliest forms of the story were a lost Castilian version, perhaps about 1250, and a Portuguese version, also lost, composed about 1370 by Vasco de Lobeira of Porto. Most likely these earlier versions were in verse. Instead of these, we have a Spanish version of almost a hundred years later, written by Garci-Ordóñez de Montalvo about 1465, but first printed in 1508. This prose romance is one of the three spared by the licentiate and the barber at the burning of Don Quixote's books, and the barber's reason is that 'it is the best of all the books of this kind.' Its hero is Amadis, the model of every knightly virtue, son of King Perion of Gaul and Elisena, Princess of Brittany; he is sent away to Scotland, where he falls in love with Oriana, the incomparable daughter of King Lisuarte of England, and the narration of the course of this love story, with its varied adventures, wide journeys into foreign lands, numberless struggles with knights, giants, and robbers, forms the chief subject of the romance. The work is wearisome from its length, but it contains many pathetic and striking passages, and has great value as a mirror of the manners of the age of chivalry.

The Spanish Amadis romances consist of twelve books, of which the first four contain the history of Amadis of Gaul. The earliest existing version of this is, as has been said, that of Montalvo, and the earliest edition now in existence bears the date of 1508. He himself added a fifth book containing the adventures of Esplandian (1510), the eldest son of Amadis and Gloriana; later writers have multiplied the posterity of the old hero. Already in 1510 appeared a sixth book, with the history of Florisando, his nephew; in 1514, 1526, and 1535 respectively, a seventh, eighth, and ninth book, with the wonderful histories of Lisuarte of Greece, a son of Esplandian, and Perion of Gaul, and the still more wonderful history of Amadis of Greece, a great-grandson of the Gallic hero. Then follow Don Florisel of Niquea and Anaxartes, son of Lisuarte, whose history, with that of the children of the latter, fills the tenth and eleventh books. Lastly, the twelfth book, printed in 1546, narrates the exploits of Don Silves de la Selva,

son of Amadis of Greece and Finistea. A French translation appeared in 1540, an Italian in 1540, an English in 1583, while a version in German was published in 1583. The French translators increased this series of romances from twelve to twenty-four books; the German, to thirty. Lastly, a Frenchman, Gilbert Sauvier Duverdiér, at the beginning of the 17th century, arranged all these romances into a harmonious and consecutive series, and with his compilation in seven volumes, the *Roman des Romans*, brought the history of Amadis and the series of about fifty volumes to a close. A version of the old romance in French was published by Creuzé de Lesser in 1813; in English, by William Stewart Rose, in 1803; while the literary skill of Southey produced in 1803 an abridgment that is still readable. On the other hand, Wieland's *Neuer Amadis* has nothing in common with the more ancient Amadis, except the title. See Baret, *De l'Amadis de Gaule* (Par. 1873); and Braunfels, *Amadis von Gallien* (Leip. 1876).

Am'adou (Fr.) is obtained from two species of Hymenomycete Fungi, *Polyporus igniarius* (hard amadou, or touchwood) and *P. fomentarius* (soft amadou, or German tinder). They grow upon old trees in Britain, and on the continent of Europe. They are used as styptics for stanching slight wounds; and when steel and flint were in general use for striking fire, were much employed as tinder, being prepared for this purpose by boiling in a solution of nitre. Attempts have also been made at their cultivation. The soft amadou is used for making small surgical pads, for which its elasticity peculiarly fits it. It is also employed by the Laplanders and others for Moxa (q.v.). It is sometimes made into razor-strops, and this use is likewise made of *P. betulinus*.—*P. officinalis*, the *Agaricon* of Dioscorides, which grows upon larch-trees in the south of Europe, is a drastic purgative, now rarely employed. *P. suaveolens*, which grows upon the stems of willows, and is easily recognised by its anise-like smell, was formerly employed in medicine, in cases of consumption, under the name of *Fungus salicis*. All these species are very similar in appearance. Another species of the same genus, *P. destructor*, is one of the fungi known by the name of Dry Rot (q.v.).—The remarkably light wood of *Hernandia guanensis*, a shrub of the natural order Thymelæaceæ, is readily kindled by flint and steel, and is used in Guiana as amadou.

Amal'ekites, a warlike, nomadic tribe in the SW. of Palestine and the peninsula of Sinai. From the very first, they manifested an uncompromising hostility to the Israelites, whose rear-guard they attacked after the passage through the Red Sea. In consequence of this, they received no mercy at the hands of the Israelites, when the latter had established themselves in Palestine. Saul nearly annihilated them. Twenty years later, David, while dwelling amongst the Philistines, penetrated into their land, and defeated them with dreadful slaughter. Another rising was mercilessly crushed by David, and the descendants of the survivors were finally extirpated in the days of Hezekiah, king of Judah, by the Simeonites.

Amalfi, a seaport on the Gulf of Salerno, on the W. coast of Southern Italy, is nearly encircled by mountains, and lies at the mouth of a deep ravine, 24 miles SE. of Naples. It is the seat of an ancient archbishopric, and, besides the ancient Romanesque cathedral, possesses several fine churches and a former Capuchin convent. The population is about 7000, who are chiefly engaged in the coasting trade, fisheries, and the manufacture of paper, soap, and macaroni. The history of Amalfi in the middle ages is both

important and interesting. It is said to have been founded under Constantine the Great, and was long a powerful and independent republic, having at one time a population of 50,000, besides a dependent territory ten times as large; it was governed by its own 'doges,' and was the centre of eastern trade; but about the close of the 11th century, fell under the power of the Normans. It was plundered by the Pisans in 1135, and its commercial decay was completed by a terrible storm in 1343, which destroyed its quays. The maritime laws of Amalfi (*Tabula Amalphitana*) once prevailed throughout Italy, and formed an important contribution to the *Consolato del Mare*. The unique manuscript of the Pandects (q.v.) was discovered at Amalfi; and Flavio Gioja, inventor of the compass, and Masaniello, were born there. Masaniello's house was destroyed by the great landslide of March 1924.

Amalgam, an alloy in which one of the metals is mercury. On the nature of the union, it has been observed that 'on adding successive small quantities of silver to mercury, a great variety of fluid amalgams are apparently produced; but in reality, the chief, if not the sole compound, is a solid amalgam, which is merely diffused throughout the fluid mass.' The fluidity of an amalgam would thus seem to depend on there being an excess of mercury above what is necessary to form a definite compound. Mercury unites readily with gold and silver at the usual temperature. It has no disposition to unite with iron even when hot. A solid amalgam of tin is used to silver looking-glasses.

Amalgamation is employed on a small scale in some processes of gilding, the silver or other metal being overlaid with a film of gold amalgam, and the mercury being then driven off by heat. But its most extensive use is in separating gold, and especially silver, from certain of their ores. The mercury dissolves the particles of the metal, and leaves the earthy particles; it is then easily separated from the gold or silver. This process, discovered in Mexico in 1557 by Bartolomé de Medina, is still used in Mexico, and was introduced with great success into the Californian and Australian gold-fields. The mode of application is to crush the quartz rock which serves as the matrix in which the small particles of gold are imbedded; place the fragments in a barrel or revolving drum with mercury, and agitate for some time. The mercury attaches all the gold particles to itself; and in the apparatus, when fully agitated, there is found a semi-fluid mass, which is the mercury, appearing half-congealed, and containing all the gold. It is only necessary to place this amalgam in a retort and apply heat, when the mercury sublimes over—and can be re-employed for further amalgamation—and leaves the gold in the body of the retort.

Several amalgams may be regarded as definite chemical compounds. Thus, when gold-leaf is placed in mercury, and the amalgam so produced filtered by being squeezed in a chamois-leather bag, the uncombined mercury oozes through the skin, but a definite amalgam of 2 of gold and 1 of mercury remains behind in the leather filter. Tin amalgam is employed in silvering looking-glasses, and is formed by laying a sheet of tinfoil on a table, covering it with mercury, and then placing, by a sliding movement, the sheet of glass over it. This amalgam contains 3 of mercury and 1 of tin; glass balls are silvered with an amalgam of 10 mercury, 1 tin, 1 lead, and 2 bismuth, best prepared by melting together the last three metals, and then adding the mercury.

A silver amalgam, containing about 26 per cent. of metallic silver—and, from the clusters of crystals

somewhat resembling a tree, called *Arbor Diana*, or Tree of Diana—is prepared by placing about half a teaspoonful of mercury in a small phial, and filling the bottle with a solution of nitrate of silver of the strength of 25 grains to the ounce. In the course of a few days the arborescent appearance presents itself. The amalgam used for frictional electric machines is made from 1 tin, 1 zinc, and 3 mercury, to which sand is afterwards added.

Amalia, ANNA, Duchess of Saxe-Weimar, was born in 1739, and, left a widow in the second year of her marriage (1758), by her judicious rule as guardian of her infant son, she enabled the country to recover from the effects of the Seven Years' War. She appointed Wieland tutor to her son, afterwards Grand-duke, and attracted to Weimar such men as Herder, Goethe, Musæus, Schiller; forming a galaxy of genius such as few courts were ever graced with. The battle of Jena is said to have broken her heart; she died (1807) six months after that event.

Amande de Terre. See CYPHERUS.

Amani'ta, a genus of Hymenomycete Fungi, nearly allied to the mushrooms (*Agaricus*). Several of the species are edible, notably the delicious Orange (*A. caesarea*), but the majority are poisonous. *A. muscaria*, which is pretty common in woods, especially of fir and beech, in Britain, is one of the most dangerous fungi. It is sometimes called Fly Agaric, being used in Sweden and other countries to kill flies and bugs, for which

Amanita muscaria, young

Amanita muscaria, full-grown, more reduced.

purpose it is steeped in milk. The pileus or cap is of an orange-red colour, with white warts, the gills white, and the stem bulbous. It grows to a considerable size. It contains a bitter and narcotic principle, resembling in its physiological action that of Indian hemp (*hashish*), and is used by the Kamchadales to produce intoxication. The intoxicating principle passes off in the urine of those who swallow it, a circumstance of which they or others often avail themselves, when abundance of the fungus is not at hand.

Amaranth (*Amaranthus*), the leading genus of Amaranthaceæ, an order differing from Chenopodiaceæ (q.v.), in the possession of a crowded bracteate inflorescence and membranous perianth. *A. caudatus* (Love-lies-bleeding), *A. speciosus*, *A. hypochondriacus* (Prince's Feather), and other species, are common annuals in our flower-gardens. *A. tricolor*, from China, is cultivated in the Southern United States, and is popularly known as Joseph's Coat. The spikes of *A. caudatus* are sometimes several feet in length. The dry red bracts which surround the flower retain their freshness for a long time after being gathered; for which reason the plant has been employed from early times as

an emblem of immortality.—The Globe Amaranth (*Gomphrena globosa*) and the Cockscomb (q.v.), well-known tender annuals, belong to the same natural order. The Globe Amaranth is much cultivated in Portugal and other Roman Catholic countries for adorning churches in winter. Its flowers, which are of a shining purple, retain their beauty and freshness for several years. No species

Love-lies-bleeding
(*Amaranthus caudatus*).

of the order can be regarded as a true native of Britain, although *A. blitum* is now found in waste places near London and elsewhere. *A. blitum*, *A. oleraceus*, and other species, are used as pot-herbs, but rarely in Britain. Wholesome mucilaginous qualities are very generally found in the leaves throughout the order. The seeds of *A. frumentaceus* (called Kiery) and of *A. anardhana* are gathered as corn-crops in India. —Medicinal properties are ascribed to some species of the order, particularly to *Gomphrena officinalis* and *macrocephala*, which have a high and probably exaggerated reputation in Brazil, as the popular names, '*para todo*,' &c., indicate, as cures for many diseases.

Amarapura ('city of the immortals') was founded in 1783 by Bodawpaya in place of Sagaing, on the other side of the river Irawadi. There Bodawpaya received the first British Embassy under Captain Symes. It was temporarily deserted in favour of Ava in 1822, and finally abandoned in 1857, when Mandalay became the capital of Burma. Little remains of the old city but some rows of beautiful trees and a few ruined pagodas.

Amara-Sinha, a celebrated Hindu grammarian, of whose life little is known; his date is by various authorities put at 56 B.C., the 5th century A.D., and the 11th century. He was a Buddhist; and it is believed that most of his writings perished during the persecution by the orthodox Brahmins in the 4th and 5th centuries. His *Amara-Kosha* ('Thesaurus of Amara'), a Sanskrit vocabulary, containing about 10,000 words, has been largely used by almost all the grammarians of India.

Amaravati. See AMRAVATI.

Amari, MICHELE, an Italian historian and orientalist, was born at Palermo, July 7, 1806. Hardly had he commenced his studies when his father's sentence to thirty years' imprisonment for a political offence plunged him into straitened circumstances. His love for an English lady saved him from despair, and secured him a knowledge of the English tongue. He devoted himself to Sicilian history, and in 1841 published his famous investigation into the history of the Sicilian Vespers, a masterpiece of historical criticism, which reversed the common notion that the massacre was the result of a deep conspiracy on the part of the nobles; showing that it was rather a national outbreak, occasioned by the tyranny of the foreign rulers, that really brought about the deliverance of Sicily. The book was quickly prohibited, and, as a consequence, widely read. Its publisher was imprisoned, but its author fled to France. The

revolution of 1848 recalled him to Sicily, where he was elected vice-president of the committee of war, and next sent by the provisional government on a diplomatic mission to France and England. The restoration in 1849 sent him once more into exile, from which he was recalled in 1859 to fill the chair of Arabic, first at Pisa, afterwards at Florence. In 1860 he took an active part in Garibaldi's expedition to Sicily. After the accession of Sicily to the kingdom of Italy, he was made a senator, and in 1862-4 held the portfolio of Public Instruction, afterwards returning to his chair. He presided over an orientalist's congress in 1878, and died at Florence, 16th July 1889. Important works are his *Storia dei Musulmani di Sicilia* (1853-73); *Bibliotheca Arabo-sicula* (1857); *Nuovi Ricordi Arabici sulla Storia di Genova* (1873); and *Le Epigrafi Arabe di Sicilia* (1875).

Amarylloidæ, or AMARYLLIDACEÆ, a natural order of petaloid Monocotyledons, essentially distinguished from Liliaceæ by their inferior ovary, and including many species distinguished by the beauty of their flowers. They are herbaceous plants, or when, as in the genera Agave and Fourcroya, they form woody stems, they have still the character of gigantic herbs rather than of shrubs. The greater part are bulbous-rooted. There are about 400 known species, natives of tropical or sub-tropical, and more sparingly of temperate regions, but particularly abundant at the Cape of Good Hope. A few species only are European. Many of them are much-prized ornaments of our gardens and hothouses. Amongst these are different species of Narcissus, Amaryllis, Alstroemeria, Pancratium, &c. (q.v.). To this order belong the Snowdrop and Snowflake, and it includes also the American Aloe (*Agave*). *Sternbergia lutea* is said to be the lily of the field referred to in the Sermon on the Mount. The properties of the Amarylloidæ are rarely very distinct; the Agave (q.v.), however, yields its juice, the bulbs of snowdrop and daffodil are emetic, and the juice of *Hemeranthus toxicarius* is used by the Hottentots as an arrow-poison.

Amaryllis, a genus of bulbous-rooted herbs of the natural order Amarylloidæ (q.v.), contains a large number of species, natives of the warmer regions of the globe. Many of them have flowers of very great beauty, and are extensively cultivated by florists, who have also produced many varieties and hybrids.

Amasia, a town in the province of Sivas, in Asia Minor, in the deep valley of the Yeshil-Irmak. The ancient town, long capital of the kings of Pontus, was the birthplace of Strabo. There are numerous interesting remains of antiquity, particularly the tombs of the kings of Pontus. Much silk is produced in and around Amasia; also wine, cotton, corn, and madder. Silver, copper, and salt mines are wrought in the neighbourhood. Silk and salt are the chief articles of export. Pop. 35,000, of whom about one-third are Christians.

Amasis, a king of Egypt, of humble origin, who rose to be general, and when sent to put down an insurrection, joined the rebels, and was proclaimed king (570 B.C.). He cultivated the friendship of the Greeks, opened up to them the commerce of Egypt (previously confined to Naucratis), married a Greek wife, and took a body-guard of Greeks into pay. Pythagoras and Solon are said to have visited him. For his alliance with Polycrates, see POLYCRATES. During his reign of 44 years, he greatly promoted the prosperity and adornment of Egypt.

Amateur (Fr.), one who does anything for love, as distinguished from one who makes it a profession. There is no general definition of an

amateur applying to all sports, and different associations are by no means in accord. Thus, by the Amateur Athletic Association an amateur is defined as 'one who has never competed for a money-prize or staked bet, or with or against a professional for any prize, or who has never taught, pursued, or assisted in the practice of athletic exercises as a means of obtaining a livelihood.' By the rules, again, of the Amateur Rowing Association, 'no person shall be considered an amateur oarsman, sculler, or coxswain, (1) who has ever taken part in any open competition for a stake, money, or entrance-fee; (2) who has ever knowingly competed with or against a professional for any prize; (3) who has ever taught, pursued, or assisted in the practice of athletic exercises of any kind for profit; (4) who has ever been employed in or about boats, or in manual labour for money or wages; (5) who is or has been by trade or employment for wages a mechanic, artisan, or labourer, or engaged in any menial duty.' The bicycling rules differ, and certain competitions are allowed between amateurs and professionals; while many so-called amateurs are men in the pay of manufacturers of bicycles, and ride in races for the purpose of advertising their employers' machines. In cricket it has been said that the difference between amateur and professional is, that the amateur receives two or three times as much money as the professional. In lawn-tennis and archery contests, money-prizes are openly played for, and nobody thinks of calling the players professionals. In golf, the line between amateur and professional has always been difficult to draw, on account of the number of boys employed to carry clubs, who afterwards develop into tradesmen. The latest delivrance on the subject defines an amateur as one who does not play for, or accept, money prizes in a competition open to professionals.

Amati, a family of Cremona, famous violin-makers in the 16th and 17th centuries. Its most illustrious members were Andrea (died about 1577); his younger brother Nicola (flourished 1568-86); Andrea's two sons, Antonio (flourished 1589-1627) and Geronimo; and the latter's son, Niccolò (1596-1684), the master of Guarneri and Stradivari. See VIOLIN.

Amatitlan, a deep lake in the Central American state of Guatemala, surrounded with high and precipitous rocks of volcanic origin. It empties into the Pacific Ocean through the river Michatoyat. Near the banks of the lake are many hot springs, and on the river is the town of Amatitlan, as late as 1840 but a miserable Indian village, but now, through the introduction of the cochineal, an active town of 10,000 inhabitants.

Amaurosis (Gr. *amauros*, 'obscure') is the name applied to total blindness when no change can be seen in the eye sufficient to account for it. *Amblyopia* is used to denote partial loss of sight under similar circumstances. The meaning of these terms has become very much more limited since the invention of the Ophthalmoscope (q.v.), which has rendered visible, in the interior of the eye, the cause of loss of sight in many cases where it was previously unknown. They are still, however, unfortunately sometimes used to denote loss of sight from atrophy of the optic nerve (see the article EYE). Amaurosis—for which an old term was *Gutta serena*—and amblyopia may occur in the course of various diseases, especially disease of the brain, Bright's disease, diabetes, hysteria; may result from a blow on the eye; or may be present, usually only in one eye, from early life (congenital amblyopia). Amblyopia, much more rarely amaurosis, may be produced by large doses of quinine, or by the prolonged and excessive use of alcohol

and other drugs, or by inhalation of certain fumes, but far most commonly by tobacco (toxic amblyopia). The treatment of these conditions is the removal of their cause, when ascertainable. In toxic amblyopia, abstinence from the drug which produced the disease usually results in cure, unless the case be of long standing and great severity.

Amazon, or **AMAZONS** (Portuguese *Amazônias*; from an Indian word meaning 'boat destroyer,' referring to the tidal wave at its mouth), is the largest river of South America and of the globe, and is also known locally as Marañon, Orellana, Solimoes, Parana-tinga, and Parana-uassu. According to geographical usage, the name Marañon belongs properly to the more northern of its two main head-streams, rising in Lake Lauricocha (Peru) about 10° 30' S. lat., 76° 10' W. long. Most geographers consider this stream (frequently called the Tunguragua) as the true Amazon; but some late writers insist that the river Apurimac, or Ucayale (the more southern of the two great head-streams), is the true Amazon. The Ucayale is some 320 miles longer than the Tunguragua. It is commonly said that the river Amazon, to its remotest source, is nearly 4000 miles long; but by the best estimates it would appear that at the outside its length does not much exceed 3400 miles. The Upper Marañon is the only stream that breaks through the central Cordillera of Peru; but five other streams, all tributaries of the Ucayale, cut through the magnificent eastern chain of the Andes, as also does the Marañon itself. Most of the upper branches flow in deep mountain gorges, which, though much elevated, have a hot climate. East of the Cordillera the vast forest-plain is entered, which stretches from the sub-Andean foothills to the sea. It is a region rich in botanical treasures, having a fertile soil and a prodigiously large rainfall. Owing to this rainfall, the country is traversed by a very great number of large navigable rivers, either direct or indirect affluents of the Amazon, and many of them scarcely known even by name to the geographer. Steam navigation has been introduced on many of the larger branches; but the natural resources of the country are very little developed.

The principal tributaries from the north are the Napo, the Putumayo, the Japurá, and the Rio Negro; from the south the Javary, the Jutahy, the Juruá, the Purus (with its great affluent the Aguiry), the Madeira (itself the recipient of mighty rivers, such as the Beni and the Mamore), the Tapajos, the Xingu, and the Tocantins, which receives the waters of the Araguay. For a considerable distance the main river forms the boundary between Peru and Ecuador; but its course lies chiefly through the northern half of Brazil, its general direction being to the NNE. Its mouth is crossed by the equator. The drainage area of the river is placed at 2,500,000 sq. m., or two-thirds the area of Europe; and the main stream and its tributaries are said to afford over 25,000 miles of water-way suitable for steam navigation. Many of the narrow side-channels, so characteristic of the Amazonian forest-plains, are navigable also, either by steamboat or by smaller craft, such as the canoes in which the india-rubber and other products of the forest are collected; and it is stated that the total length of navigable waters in the system is probably not less than 50,000 miles. There is some dispute as to whether the islands at the mouth of the river are really deltaic; but it is certain that further inland a great part of the country is insular and river-built, and consequently of a true delta formation. In the rainy season, much of this region is subject to overflow. The main channel, at the mouth, is 50 miles wide, exclusive of the Pará mouth and the island of Joannes. The

average flow of the river is placed at 2½ miles per hour. The tides are noticed for about 400 miles up the river. The tidal phenomenon called the *bore* (here known as *Pororoca*) is very destructive in the main channel of the lower river, near its mouth; and from this phenomenon the Indian name of the river (*Amassona*, 'boat-destroyer') is said to be derived. There is, however, some reason to think that the name was really derived, as stated by the older writers, from the female warriors seen by early explorers in the valley of this river. The name *Marañon* is derived from a voyager who visited the river in 1503; *Orellana* was the name of one who sailed on it in 1540.

The outflowing current of the Amazon in times of flood is sometimes perceived at a distance of 200 miles from the land. The climate of the river-valley, though hot and very damp, is greatly mitigated by its trade-winds, which blow from the east with little interruption throughout the dry season. These winds at some periods of the year become very stormy and even dangerous to unskilled boatmen. The river abounds in fish in very great variety of species, some of them of great value as food-fishes; and turtles and alligators are plentiful, as well as porpoises and manatees. The main river is fullest from March to June inclusive, and lowest in August and September. The surrounding country is very thinly peopled, and many of the native tribes are savages of wild and degraded character. The river is open to the commerce of all nations, but trade has been impeded by import and export duties. Mention should be made of the river *Cassiquiare*, a stream ordinarily navigable, which flows from the *Orinoco* 180 miles to the *Rio Negro*, the largest northern tributary of the Amazon. *Pará* is the principal outlet by sea of the commerce of the Amazon Valley. This valley has been the field of many unsuccessful attempts at colonisation. The immense extent of its forests (almost everywhere nearly impenetrable by land on account of the enormous growth of lianas, or woody vines of countless species) has greatly hindered the progress of agriculture. Many useful and some highly valuable timber-trees grow on the river. The botany of the country is not very well known, many of the trees having flowers only on the upper branches, the lower portions being cut off from the influence of the light by the dense foliage; hence the study of the flowers is not easy. It is one of the paradoxes of the region that this forest, the largest and densest in the world, imports from North America much of its building timber, and some of the steamers on the river have found it cheaper to consume English coal than to burn the wood which grows so abundantly on every side.

One of the leading pursuits of the lower valley is the shipment to *Pará* of india-rubber and Brazil-nuts, which are largely collected by the Indians and the scattered colonists. But even this employment is seldom remunerative. The rubber here found is of excellent quality and high price; but the times, places, and other conditions of gathering cargoes are extremely uncertain. The river and the forests afford to the natives all things which are required to satisfy their simple and artificial needs; consequently no systematic industry can flourish except on a relatively small scale. The western part of the Amazon Valley is, of course, more elevated than the rest of the great forest; and between its tributary streams there are occasionally found lofty mountain-spurs, which are connected with the grand range of the Eastern Andes. This region affords quinine-yielding barks, coca, cacao, sugar, coffee, palm-wax, *ipecaçuana*, *copaiba*, *sarsaparilla*, vanilla, and other valuable vegetable products, and a considerable amount of

gold is procured in it. The scenery is finer and the productions are more varied than in the lower valley; but the climate is not any healthier.

See A. R. Wallace, *Travels on the Amazon and Rio Negro* (1853; new ed. 1889); H. W. Bates, *The Naturalist on the Amazon* (1864; new ed. 1892); Agassiz, *A Journey in Brazil* (1868); Brown and Lidstone, *Fifteen Thousand Miles on the Amazon* (1878); books by H. H. Smith (1880), Mrs. Mulhall (1882), Mozaans (1910), Algot Lange (1912 and 1914), Woodroffe (1914).

Amazo'nas, (1) the northernmost state of Brazil, has an area of 730,000 sq. m., and a population of 500,000. Its surface is covered with virgin forests. The capital is *Manaos*.—(2) A department of Peru, bounded on the N. by Ecuador with an area of 14,000 sq. m. Pop. 70,650.

Am'azons, in Greek Mythology, a nation of women who suffered no men to remain among them, but marched to battle under the command of their queen. They held occasional intercourse with the men of the neighbouring states. If boys were born to them, they either sent them to their fathers or killed them. But they brought up the girls for war, and burned off their right breasts, that they might not be impeded in bending the bow. From this custom they received the name of Amazons—that is, 'breastless.' Such is the ordinary tale; and it is idle to look for any historical evidence to prove the actual existence of such a nation. Ebers insisted that Greek imagination made the institution of armed priestesses, as found amongst various races, into nations of women warriors; and some recent archaeologists derive the tradition from the armed priestesses or women warriors depicted on Hittite sculptures. From the Circassian word 'Maza,' signifying the moon, some referred the myth of the Amazons to the worship of the moon. Three nations of Amazons have been mentioned by the ancients: (1) The Asiatic Amazons, from whom the others branched off. These dwelt on the shores of the Black Sea, and among the mountains of the Caucasus, especially in the neighbourhood of the modern Trebizond. They are said to have at one time subdued the whole of Asia, and to have built Smyrna, Ephesus, Cumæ, and other cities. Their queen, Hippolyte, or, according to others, Antiope, was killed by Hercules, in fulfilling the ninth of the labours imposed on him by Eurystheus, which consisted in taking from her the shoulder-belt bestowed on her by Ares. On one of their expeditions, the Amazons came to Attica, in the time of Theseus. They also marched under the command of their queen, Penthesilea, to assist Priam against the Greeks. They even appear upon the scene in the time of Alexander the Great, when their queen, Thalestris, paid him a visit, in order to become a mother by the conqueror of Asia.—(2) The Scythian Amazons, who in after-times married among the neighbouring Scythians, and withdrew farther into Sarmatia.—(3) The African Amazons, who, under the command of their queen, Myrina, subdued the Gorgons, marched through Egypt and Arabia, and founded their capital on the Lake Tritonis, but were then annihilated by Hercules. The myth of the Amazons was a fertile subject in ancient Greek art, and their historical existence and locality are gravely discussed by rationalising historians and geographers like Arrian and Strabo. Even later than the middle ages they were believed to exist in Africa and America, and the name of the river Amazon was associated with this belief.—In early Christian Ireland, down till the end of the 7th century, the women fought regularly in the tribal armies along with the men. Modern Amazons constituted part of the army of Dahomey till the French conquest in 1892; they were subjected to severe and systematic

discipline, and were formidable and by no means merely ornamental soldiers.

Ambala. See UMBALLA.

Ambassador. Diplomatic envoys are of four kinds: (1) Ambassadors accredited directly to a foreign sovereign, and personally representing the sovereign who appoints them. (2) Ministers accredited to a foreign sovereign or state, who do not represent the sovereign, but only the state which sends them, and its affairs. These are usually called envoys extraordinary and ministers plenipotentiary. (3) Ministers resident, called simply envoys. These differ not in representative power, but in dignity. (4) *Chargés d'Affaires* accredited to foreign ministers. The term ambassador is commonly used to denote any kind of diplomatic minister. Besides representing his sovereign, the ambassador keeps him well informed as to what goes on in the country where he resides; defends the interests of his fellow-countrymen abroad; and promotes goodwill between his own country and that in which he dwells. He carries with him credentials, and instructions for his own guidance. The ambassador of the first rank is entitled to public and private audiences with the sovereign to whom he is sent; a minister of the second class, to private audiences only. In the performance of all his diplomatic duties, an ambassador is understood to represent, not only the affairs, but the dignity and the power of his master; and by the law of nations he has many important rights and privileges, the chief of which is exemption from the control of the municipal laws of the nation wherein he is to exercise his functions, an exemption that is not confined to the ambassador himself, but is extended to all his suite, including not only the persons employed by him in diplomatic services, but his wife, chaplain, and household generally. But there is a dispute among legal writers whether this exemption extends to *all crimes*, or whether it is limited to such offences as are *mala prohibita*, as coining, and not to those that are *mala in se*, as murder. But as the security of an ambassador in conducting the intercourse of nations is of more importance than the punishment of a particular crime, there are few modern examples of an ambassador being punished for any offence. The full exemption of an ambassador from legal process in civil cases was first recognised by 7 Anne, chap. 12, a statute passed to appease the wrath of Peter the Great of Russia on learning that his ambassador had been actually arrested, and taken out of his coach in London, for a debt of £50. It was, however, merely a declaratory act, confirming the common law and law of nations.

But although an ambassador is not amenable to any tribunal of the country he resides in, he cannot misconduct himself with impunity. He must respect the laws and customs of the country in which he is officially resident; and if he violates or offends these laws and customs, he may be complained of to the court or government which he represents; or if the offence is of a very serious nature, his recall may be demanded, or the sovereign to whom he has given such offence may dismiss him peremptorily, and further require that he be brought to trial in his own country. It hardly need be added, that if an ambassador is guilty of an offence which threatens the safety of the state, he ceases to enjoy the privileges of the exemption in question.

There are some other and inferior privileges which are very generally allowed to ambassadors: they are, for instance, permitted the free exercise of their religion; they are, in general, exempted from direct taxation, they have special letter-bags, and they are usually allowed to import their goods

without paying any custom-house duties—a privilege, however, which, being liable to abuse, has been limited. It is usual to ascertain whether an appointment will be acceptable, since a sovereign can refuse to receive an ambassador.

Ambassadors of the first class ordinarily reside regularly at the court to which they are accredited. But sometimes ambassadors are sent on special occasions, as for the negotiation of treaties, when they receive additional powers, and have the higher rank of Ambassadors Extraordinary. The employment of permanent ambassadors originated in the 15th century. The British diplomatic corps included till lately nine ambassadors, in the restricted sense, accredited to Vienna, Paris, St Petersburg, Constantinople, Berlin, Rome, Washington, Madrid, and Tokyo. The envoys to Portugal, Brazil, and Belgium have now the higher rank. Till 1893 the United States sent to Europe only envoys extraordinary and ministers plenipotentiary, who ranked in the second class of diplomatic agents. Ambassadors were thereafter accredited to London, Paris, and Berlin.

The 'rupture of diplomatic relations' by the withdrawal, or still more sharply, by the dismissal of an ambassador, is tantamount to a declaration of war, and now often takes the place of any more formal manifesto or proclamation—which indeed is designed rather for the information of neutrals (see NEUTRALITY). Some authorities on international law deny that any declaration is imperative. After the diplomatic rupture, the interests of the enemy's subjects in the country of either belligerent are entrusted by arrangement to one or other of the ambassadors of neutral powers. The usual title for ambassadors proper is 'excellency,' which is often conferred also on the lower ranks of ministers. See ENVOY, CHARGÉ D'AFFAIRES, CONSUL, and INTERNATIONAL LAW.

Amber, a decayed city of Jeypore (q.v.).

Amber (through Spanish from Arabic *ambar*, 'ambergris,' from its supposed resemblance), a substance analogous to the vegetable resins, and in all probability derived from various extinct coniferous trees of the Tertiary period, although now appearing, like coal, as a product of the mineral kingdom. It is usually of a pale-yellow transparent colour, sometimes reddish or brownish, and almost opaque, and it is occasionally greenish, bluish, or violet coloured. It occurs in irregular lumps, grains, or drops; has a perfectly conchoidal fracture, is slightly brittle, emits an agreeable odour when rubbed, melts at about 536° F. (280° C.), and burns with a bright flame and pleasant smell. It becomes negatively electric by friction, and possesses this property in a high degree—which, indeed, was first observed in it, and the term electricity is derived from *elektron*, the Greek name of amber. The specific gravity of amber is 1.065 to 1.070. Deprived, by means of ether, of all its soluble constituents, its composition is similar to that of camphor, $C_{10}H_{16}O$. An acid called succinic acid (named from the Lat. *succinum*, 'amber') is obtained from it. It was highly prized by the ancients for personal and household ornaments. There is mention of it in Homer; and in lake dwellings and ancient graves in various parts of Europe amber ornaments have been found. It was regarded as a charm against disease and witchcraft. Necklaces of amber beads, under the name of *lammer beads* (Fr. *l'ambre*), were formerly much worn by the peasantry, especially the fisher-folk, in Scotland, partly on account of their supposed virtues. Large quantities are still consumed in Mohammedan worship at Mecca, and it is in great demand throughout the East. It was obtained by the ancients from the coasts of the

Baltic Sea, where it is still found, especially between Königsberg and Memel, in greater abundance than anywhere else in the world. It is there partly cast up by the sea, especially after storms, partly obtained by means of nets, and partly by systematic dredging; and is also got by digging in the 'blue earth' and other superficial strata near the coast, in which it is most plentifully found. Amber is found occasionally in diluvial deposits, as in the gravel near London, and sparingly along the east coast of England; but it is very rare in Britain. It is obtained in small quantities from the coasts of Sicily and the Adriatic, and is found in different parts of Europe, in Siberia, Greenland, Kamchatka, Australia, United States, Burma, &c. It sometimes encloses crustacea, centipedes, and insects of species which no longer exist. Leaves have also been found inclosed in it. Specimens which contain insects or leaves being much valued, fictitious ones are often manufactured and imposed upon collectors. According to an ancient fable, amber is the tears of the sisters of Phaëthon, who, after his death, were changed into poplars. In the royal cabinet at Berlin is a piece weighing fifteen pounds, said to be the largest ever found, and valued at £1500; but it is extremely rare that pieces of ten pounds' weight are met with.

Amber had formerly a high reputation as a medicine, but the virtues ascribed to it were almost entirely imaginary. A volatile oil is obtained from it by distillation, which has the reputation of being an antispasmodic of special value in infantile convulsions. Amber is employed in the arts; for the manufacture of smokers' mouthpieces, for jewelry, and many ornamental objects. It is wrought by carving, rasping, filing, and polishing, or is turned on a lathe. Artificial amber is frequently used instead of the genuine article, which it closely resembles. It is composed of copal, camphor, and turpentine, and may be distinguished from amber by its lower melting-point, and by its readily softening in cold ether, which leaves real amber unaffected. It has been supposed that the famous Cremona violins owe their fine tone and preservation, in part at least, to the use of an amber varnish; and in the present day the production of such a varnish has occupied much attention. Amber contains two resins which in their natural condition are not soluble in spirit or turpentine. When fused, however, it is possible to incorporate boiled linseed oil and subsequently turpentine, but in this process great difficulty is experienced in avoiding overheating, resulting as it does in a dark-coloured and less limpid product. A very clear pale varnish is best obtained by heating six parts of amber, two of boiled linseed oil, and eighteen of turpentine to 752° F. (400° C.), in a strong copper vessel. See Biffum, *The Tears of the Heliades* (1896), and German works by Klebs, Waldmann, and Tesdorpf. —'The Amber Witch,' described by Meinhold, is also the subject of an opera by W. V. Wallace.

Amberg, a town of Bavaria, once the capital of the Upper Palatinate, 35 miles E. of Nuremberg. Chief buildings are the town-hall (1490) and the church of St Martin (1421), with a steeple 321 feet high. There is a large arsenal; and the principal products are firearms, earthenware, woollen cloths, ironmongery, and beer. Many of the inhabitants are employed as miners in the neighbouring mountains. In the neighbourhood is the Maria-Hilfsberg, a place of pilgrimage. Pop. 26,000.

Ambergris (i.e. 'gray amber'), a fatty substance, of an ash-gray colour, with yellow or reddish stræ, like those of marble, which is found

in lumps of from half an ounce in weight to 100 lb. and upwards, floating on the sea, or cast upon the seashore in different parts of the world, and is also taken by whale-fishers from the bowels of the spermaceti whale (*Physeter macrocephalus*). Much ambergris is obtained from the coasts of the Bahama Islands; it is also brought from different parts of the East Indies, and the coasts of Africa, Brazil, China, and Japan. It is probable that all of it is produced by the spermaceti whale, and that it is a morbid secretion in the intestinal canal of that animal, derived from the bile. It is highly valued on account of its agreeable smell, and is much used in perfumery. The finer kinds are exceedingly high in price. It has been strongly recommended for medicinal uses, but is scarcely employed in Europe; although in some parts of Asia and Africa it is much used as a medicine, and also as a condiment. Its specific gravity ranges from .780 to .926. It almost always contains black spots, which appear to be caused by the presence of beaks of the *Sepia octopodia*, the principal food of the spermaceti whale. It consists in great part (85 per cent.) of a peculiar brilliant white crystalline substance called *Ambrein*, believed to be identical with cholesterol.

Amberite (so called from its appearance), a smokeless powder made from Gun-cotton (q.v.), barium nitrate, solid paraffin, and other substances.

Ambidexterity. See RIGHT-HANDEDNESS.

Ambleside, an urban district of Westmorland, about a mile from the head of Lake Windermere, is a tourist centre for the Lake District. Rydal Mount, for many years the residence of Wordsworth; Nab Cottage, where Hartley Coleridge lodged; Fox How, a summer retreat of Dr Arnold; and The Knoll, where Miss Martineau lived and died, are near. Pop. 3000.

Amblyopia (Gr. *amblys*, 'dim,' *ōps*, 'eye'). See AMAUROSIS.

Amblyopsis, a North American bony fish, found in the Mammoth Cave of Kentucky, and interesting as illustrating in the rudimentary condition of its eyes the effects of darkness and consequent disuse. It only measures a few inches in length, is colourless, and has its small eyes covered by the skin. It seems able, however, to hear acutely, and the wrinkles of skin on its head are regarded as special feeling organs. *Typhlichthys* is a closely allied genus found in the same surroundings, while another relative, *Chologaster*, occurring in the ditches of the South Carolina rice-fields, is, as one would expect, open-eyed. The caves are tenanted by similar half-blind animals of various classes (see PROTEUS, and CAVE-ANIMALS). Truly blind fishes are only found in the unsunned ocean depths.

Amblystoma, a genus of tailed amphibians in the gill-less or Salamandroid sub-order. It is the adult form of Axolotl (q.v.), from which it differs in its mode of respiration, and in a few external characters.

Ambo (Gr. *ambōn*), a kind of reading-desk or pulpit, which in early churches was placed in the choir. The epistle and gospel were read from the ambo, and sermons were sometimes preached from it. The ambo had two ascents—one from the east, and the other from the west. In the Roman churches there were two ambos, one on each side of the choir, from one of which the gospel was read, and from the other the epistle. The name ambo was also given to an eagle-shaped reading-desk.

Amboise, a French town in the department of Indre-et-Loire, on the Loire, 15 miles by rail E. of Tours. It lies in a region so rich in vineyards that

it has been called 'the Garden of France.' The town is memorable for the Huguenot conspiracy (1560), which cost the lives of 1200 Protestants, and as the place whence was issued the Edict of Amboise (1563), conceding certain privileges to the Huguenots. The castle of Amboise from 1431 was a frequent residence of the Valois kings; the birth and death place of Charles VIII.; and since the days of Louis XI., 15,000 prisoners are said to have been confined in its subterranean 'oubliettes.' Pop. 4500.

Amboise, GEORGE OF, cardinal and prime minister under Louis XII. of France, was born in 1460 near Amboise. In his 14th year he was made Bishop of Montauban, and in 1493 Archbishop of Rouen. Initiated in early years into the intrigues of court, by his zealous services he soon secured the confidence of Louis of Orleans, who, on his accession to the throne as Louis XII. in 1498, made him his chief-minister. Thenceforward Amboise, who in the same year received a cardinal's hat, became the prime mover in all the affairs of the realm; and it was by his advice that Louis undertook that spirited Italian policy which had such great influence on the fortunes of France. After the death of Pope Alexander VI. (1503), Amboise endeavoured to raise himself to the papal see, and having failed, became the dangerous enemy of the succeeding popes, Pius III.—who occupied the papal chair only four weeks—and Julius II. To secure his own election, Amboise encouraged a schism between the French Church and the see of Rome, and convened a separate council, first at Pisa, afterwards at Milan and Lyons; but his plans were frustrated by the failures of the French arms in Italy. He died at Lyons, May 25, 1510. It was said that his vast fortune of 11,000,000 livres had been accumulated by not over-scrupulous means.

Amboyna, the most important of the Moluccas or Spice Islands belonging to the Dutch, lies SW. of Ceram, and NW. of Banda. Area, 365 sq. m. Pop. about 58,000, nearly a third Mohammedans. A bay runs into the island lengthways, forming two peninsulas, the northern called Hitu, and the southern, Leitimor. Amboyna is mountainous, well-watered, fertile, and healthy. Clove, sago, mango, and coconut trees are abundant, also fine timber for cabinet-work. The Dutch have diligently fostered the growth of the clove, and forced its culture by tyrannical methods. The Dutch took Amboyna from the Portuguese in 1605. The British settlement was destroyed by the Dutch in the infamous Amboyna massacre of 1623, for which, in 1654, Cromwell exacted compensation. The British held the island, 1796–1802. It became finally Dutch in 1814.

AMBOYNA, capital of the Dutch Moluccas, is situated on the NW. shore of Leitimor, on the bay of Amboyna, and has a good roadstead. The government buildings are in Fort Victoria. Pop. about 9000.

Ambracia, a town in ancient Epirus, on the river Arachthus, north of the Ambracian Gulf. Colonised by the Corinthians about 630 B.C., it soon attained to great wealth and importance. Pyrrhus, king of Epirus, made it his residence. On its site stands the modern town of Arta (q.v.).

Ambriz, a seaport in the north of the Portuguese territory of Angola, West Africa, exporting copper, rubber, coffee, and gums. The town of Ambriz was annexed in 1855, and was formerly the port of a small negro kingdom. See ANGOLA.

Ambrose, ST, one of the most celebrated of the ancient fathers of the church, was born about the year 340, probably at Treves, where his father.

as Prefect of Gaul, was wont to reside. Ambrose received a fortunate omen even in his cradle: a swarm of bees covered the slumbering boy; and the astonished nurse saw that the bees clustered round his mouth, without doing him any harm. His father, perhaps remembering a similar wonder related of Plato, foreboded from this a high destiny for Ambrose. He received an excellent education, and went with his brother Satyrus to Milan, in order to follow the legal profession. He soon distinguished himself so much, that in 369 he was appointed, by Valentinian, Prefect of Upper Italy and Milan. In this office, his gentleness and wisdom won for him the esteem and love of the people, whose prosperity had been much injured by the troubles caused by Arianism. Accordingly, by Arians and Catholics alike, he was unanimously called to be Bishop of Milan in 374. He long refused to accept this dignity, and even left the city; yet he soon returned, was baptised, as hitherto he had been only a catechumen, and was consecrated eight days afterwards. The anniversary of this event (December 7) is still celebrated as a festival by the Catholic Church. Having sold his goods, and distributed the proceeds among the poor, Ambrose proceeded to fit himself for his new office by a course of theological study, under Simplician, a presbyter of Rome. As a bishop, he won the universal reverence of all, by his mild and gentle character; but he was severe and stern against wickedness of every kind, even in high places. Thus, he repulsed the Emperor Theodosius himself even from the door of the church, on account of his having caused the rebellious Thessalonians to be cruelly massacred by Rufinus, excommunicated him, and only restored him to the church after eight months of severe penance. Only his unflinching defiance of the court party enabled him to save the churches in his diocese from the Arian heretics; and his almost threatening earnestness probably contributed largely to the defeat of Symmachus, a wealthy prefect of Rome, who had petitioned for the restoration of the pagan worship, after the famine of 383. Ambrose's most valuable legacy to the church is his hymns, and the improvements he introduced into the service. The Ambrosian ritual, a use or liturgy still retained in the Milanese Church, is claimed for him, and he is the author of many hymns which he introduced into the Western Church. The hymn, *Te Deum Laudamus*, has been erroneously ascribed to him. For the *Ambrosian Chant*, see CHANT. Ambrose died in 397. The best edition of his works, generally ascetic in tone, and in which he followed in many things the Greek theological writers, is that published by the Benedictines (2 vols. Paris, 1686–90). Ambrose is the patron saint of Milan.—The AMBROSIAN LIBRARY there, named in his honour, was established in 1609 by Cardinal Borromeo. It now contains 180,000 volumes of printed books, and 8500 MSS.

Ambrosia (formed from Gr. *ambrōtos*, 'immortal'), in Greek Mythology, the food of the gods, as nectar was their drink. It gave to those who ate of it immortal youth and beauty. It was brought by doves to Jupiter, and was occasionally bestowed upon such human beings as were the peculiar favourites of the gods. Ambrosia was also used as a fragrant salve, which the goddesses employed to heighten their beauty; with which Jupiter himself anointed his locks; and which had the property of preserving bodies from corruption. The term was applied by Pliny, and by our early herbalists, to various plants. Hindu mythology has also its *amrita*, the beverage of the gods; and the gods of the Scandinavian pantheon were preserved in perpetual vigour by eating the apples guarded by Idun.

Ambry, a niche or recess in the wall of a church,

shut in by a door, for the purpose of holding the vestments and utensils, such as the chalices, basins, cruets, &c. used for the service of the Mass. In monastic buildings, ambries were used for various purposes, such as keeping plate, hanging towels for the monks to dry their hands with before dinner, and the like. In this sense, the term ambry seems to have been applied to any kind of cupboard which was closed in and locked, and it is so used in Scotland at the present day.

Ambulacral System (Lat. *ambulare*, 'to walk'), a term applied to a partly locomotor, partly respiratory, system in the Starfish group of animals. The term water-vascular is on the whole preferable. The system usually consists (1) of five radial canals, giving off tube-feet, which are

A, cross section of complex supply-canal of a starfish—the so-called stone-canal (after Gegenbaur). B, diagrammatic plan of system in a starfish (after Gegenbaur): r, radial canals, giving off branches, b, to suckorial tube-feet, s, with lateral and internal reservoirs or ampullae, a; c, circular canal, with side reservoirs or Polian vesicles, p, with supply or stone canal, s.c., and special entrance or madreporic plate, m

generally suckorial; (2) of a circular canal surrounding the mouth, and uniting the oral ends of the five radials; and (3) of a special supply-canal, by which water enters the system. For further description and figures, see the articles ECHINODERMATA, HOLOTHURIANS, SEA-URCHINS, and STARFISHES.

Ambulance (Fr.), originally a *walking* or movable hospital, but since the Crimean war a wagon for the conveyance of sick and wounded. The term *Field-ambulance* designates a complete unit of succour for sick and wounded soldiers. Three of these units, each commanded by a lieutenant-colonel of the Royal Army Medical Corps, form part of the British infantry division (see DIVISION). Each field-ambulance, accommodating 150 patients, is divided into three sections, each commanded by an officer of the Medical Corps. Each section has a Bearer Sub-division, consisting of 6 stretcher squads of 6 bearers each, with a few orderlies, and a Tent Sub-division of about 70 rank and file, which includes Army Service Corps drivers, &c., and the total personnel amounts to 241 officers and men, with 51 horses. There are 10 ambulance wagons, 7 being motors and 3 horsed,

3 water-carts, 11 carts and wagons for medical stores and baggage. The ambulance wagon can carry 4 cases lying down, 2 lying and 4 sitting, or 12 sitting up.

A British cavalry division has 4 cavalry field-ambulances, on the same pattern as the above, but of only half the size. During an action the Battalion (q.v.) stretcher-bearers (4 per company, or 16 in all) pick up the wounded as they fall and carry them to the regimental dressing-station, if one has been formed, where they are attended to by the medical officer of the unit, or to the tent sub-division of the field-ambulance. The stretcher-bearers of the field-ambulance assist in this work. After the action, the ambulance wagons drive on to the field.

It is very important that the field-ambulances should be emptied of patients as expeditiously as possible, if there is probability of further fighting. This is done to a clearing hospital, an establishment adapted for 200 sick, using the field-ambulance's own vehicles, and country carts, and empty supply and ammunition wagons that are returning to the advanced base for fresh supplies. If a railway then becomes available, there is an equipment of hospital trains, each capable of carrying 100 patients lying down. If a suitable water-way is available, there will be ambulance boats and barges. If the country is roadless, a corps of coolies carry on stretchers, or mules are equipped with cacolets, which are seats swung on each side of the animals. Female nurses are not employed in connection with ambulances or clearing hospitals, but only in stationary and general hospitals, and to a small extent on ambulance trains.

Ambulance wagons did not exist in the British army during the Crimea. The sick and wounded were carried by the sailors in hammocks, in ordinary transport wagons, and in ambulances borrowed from the French; nor were there any trained stretcher-bearers, field-hospitals, or hospital ships; the bandsmen alone were available to carry away their wounded comrades, and the regimental surgeons dressed their wounds on the field. To meet this deficiency, Lord Herbert's commission was appointed in 1857 and 1858, and effected considerable improvements, amongst others introducing into the service an ambulance wagon of similar type to that used by the French in the Crimea. Though restricted in military language to the wagon above described, the expressions *ambulance* (as of St John's or Red Cross societies) and *ambulance corps* are popularly used to cover the whole modern organisation for the immediate relief of wounded soldiers on the field of battle, called officially a *Bearer Sub-division* (q.v.) in the British army, and a Sanitary Detachment in the German.

A civil ambulance association was originated in 1877 by the Knights of St John, with the object of giving practical instruction respecting first aid to sufferers from accidents. Its success has led to the establishment of a St Andrew's Ambulance Association in Scotland, and of local centres throughout the kingdom. Classes are trained by its lecturers, and in most large towns ambulance wagons and attendants can be summoned by telephone from the society's office. Most members of the British police force now hold either the certificate or the higher medal of the association.

Ambuscade, a manœuvre in warfare, whose general nature is indicated by the original Italian *imboscata* ('concealed in a wood'), but which now applies to any attempt to attack an enemy by lying in wait and coming upon him unexpectedly. The tactics of modern times render ambuscades unusual in civilised warfare. It is something more sudden and unexpected than a 'surprise.'

See Colonel Malleeson's *Ambushes and Surprises* (1883).

Ameer, or AMIR, another spelling of Emir (q.v.).

Amelanchier (so called from the Savoy name of the medlar) is a small but widely dispersed genus of small trees belonging to the order Rosaceæ, sub-order Pomeæ, and planted in this country on account of their pretty foliage and racemes of white flowers, which appear early in spring. They are very hardy. *Amelanchier botryapium*, an American variety, is sometimes called June-berry, from its early ripening; and *A. ovalis* produces a pleasant fruit, which makes excellent puddings.

Amen, a Hebrew word of asseveration, equivalent to 'Yea,' 'Truly,' which has been commonly adopted in the forms of Christian worship. In Jewish synagogues, the Amen is pronounced by the congregation at the conclusion of the benediction given at parting. Among the early Christians, the prayer offered by the presbyter was concluded by the word Amen, uttered by the congregation (cf. 1 Cor. xiv. 16). Justin Martyr is the earliest of the fathers who alludes to the use of the response. In speaking of the sacrament of the Supper, he says that, at the close of the benediction and prayer, all the assembly respond 'Amen.' According to Tertullian, none but the faithful were permitted to join in the response. Up to the 6th century, it was the custom for those present at the Lord's Supper to utter a loud 'Amen' at the reception of the bread and wine, and to join in shouting 'Amen' at the close of the consecration. The same custom was observed at baptism, where the sponsors and witnesses responded vehemently. In the Greek Church, this word was pronounced after the name of each person of the Trinity; and at the close of the baptismal formula, the people responded. At the conclusion of prayer, it signifies (according to the English Church Catechism) *So be it*; after the repetition of the Creed, *So is it*. The Roman Catholic version of the New Testament (Rheims, 1832) substitutes Amen for the 'verily' of our Authorised Version, it being the word used in the original Greek. The Mohammedans also use this word in their service.

Amende-honorable (Fr., 'honourable compensation') was in France in the 9th century a public and humiliating confession made by traitors and other offenders in court, after being stripped of their shirts by the executioner, and having had other indignities inflicted on them. In England, the phrase is used figuratively of a full and frank apology sufficient to atone for the wounded honour of another.

Amendment, in judicial proceedings, means the correction of any errors or the supplying of any omissions in the record of a civil action or in a criminal indictment. In criminal proceedings greater strictness is observed, but in civil actions almost any amendment will now be allowed by the courts which does not embarrass or surprise the opponent. In civil proceedings leave of court is usually necessary; but under modern statutes there are large powers of amendment of claim or counter-claim without leave. In Scotland, in proceedings in the Court of Session, it is competent, under an Act of Sederunt passed in 1907, to make amendments extending the declaratory or pecuniary conclusions of the summons, or altering the instance of the action, subject to conditions as to expenses.

In the United States, amendments were authorised to be made by courts of general jurisdiction at common law. The equitable power of amendment of pleadings and proceedings in the courts, and in all the various steps in a cause, has been conferred on the United States courts by acts of

Congress. The changes and additions made to the constitution of the United States during the last hundred years are called the amendments. The senate may amend money bills passed by the House of Representatives, but cannot originate such bills.

In British parliamentary procedure, the object of an amendment is generally to effect such an alteration in a question or motion as will make certain members vote in favour of it who, without such alteration, must either have voted against it, or have abstained from voting. This is quite distinct from the false amendment, which, like the 'previous question,' is intended to evade an expression of opinion on the main question, and which is effected by moving the omission of all the words in the question after the word 'that' at the beginning, and the substitution of other words of a different import. Proper amendments are obviously of great convenience to a deliberative assembly, because otherwise they would be compelled to express a positive or negative opinion upon the whole question as put. The amendment may even contain an alternative proposition wholly opposed to the original question. An amendment is generally put to the House in the form, 'That the words proposed to be left out stand part of the question;' the insertion or addition of new words being subsequently voted on. No amendment can be made in the earlier part of a question, after the later part has been considered. Words which have been voted to stand part of the question cannot afterwards be amended. An amendment of an amendment may be proposed, where the original amendment is simply to leave out words; and the original amendment becomes for the time the question. The 'previous question,' which, in effect, is designed to prevent the main question being put, can only be moved when the main question is before the meeting, and therefore not during the discussion of an amendment; but when the question or amendment has been determined, the previous question may then be moved. An amendment does not require notice, although notice is usually given. It must, however, be reasonably relevant to the original question, and should not render the original question, as altered, unintelligible. The amendments moved to public and private bills at their various stages are all technical in form, and all that need be said is that, according to practice, amendments are not moved to the motion for the first reading of a bill. The rules adopted in parliament as to amendments to questions should, as far as possible, be followed by the chairmen of public meetings. In particular, it is desirable to dispose of one amendment before another is proposed.

Amenôphis, AMUNOPH, or AMEN-HOTEP is the name borne by four Egyptian kings of the 18th dynasty, which began with Amasis or Aahmes I., about 1700 B.C. See EGYPT, AKHNATON.

Amentaceæ, a vast order of very varying limits, consisting of trees and shrubs, whose flowers are unisexual, the male flowers, and very often also the female flowers, disposed in *amenta* or Catkins (q.v.), and the perianth either wanting or incomplete. The Amentaceæ include as sub-orders the Cupuliferæ (see Alder, Birch, Hazel, Hornbeam, Beech, Oak, Chestnut) and the Juglandaceæ (see Walnut, Hickory). In the most comprehensive sense, the Amentaceæ are also frequently reckoned to include the Myricaceæ (see BOG MYRTLE), the Casuarinaceæ (see CASUARINA), the Salicaceæ (see WILLOW), and even the Piperaceæ (see PEPPER).

Amenthes, the unseen world of the ancient Egyptians, the Hades of the Greeks, who borrowed their ideas about the lower world from Egypt. The

passage across the river, the islands of the blessed, Cerberus, and the judgment of the dead, all have their original in Amenthes, the localities of which, and the account of its divinities, are described in the famous Book of the Dead (q.v.), as well as in pictorial representations. The principal scene is the judgment seat of Osiris, the judge of the dead, before whom the dead are carried by the goddess Ma ('righteousness'), while Horus and Anubis weigh out their deeds. See EGYPT.

America has since the beginning of the 16th century (see *History*, below) been the general name for the western continent and its adjacent islands, forming the main body of land found in the western hemisphere. America has an area of about 16,500,000 sq. m., and is larger than Europe and Africa together. It is about four times as large as Europe, five times as large as Australia, and half as large again as Africa; but is considerably smaller in area than Asia. It is customary to regard Greenland as a part of America; while the adjacent island of Iceland, partly in the western hemisphere, is usually associated with Europe. The other principal American islands in the Atlantic are Newfoundland, Cape Breton, Anticosti, Prince Edward Island, Long Island, the Bermudas, the Antilles or West Indies, Joannes, the Falkland Islands, Staten Land, and South Georgia. At the southern extremity of America lies the archipelago of Fuegia (Tierra del Fuego). In the Pacific are the Aleutian Islands, Kadiak, the Alexander and Queen Charlotte groups, Vancouver and other British-Columbian Islands; the Santa Barbara group, Revilla-Gigedo, the Pearl Islands, and others in the Gulf of Panamá, the Galápagos, Juan Fernandez and the associated islets, Chiloe and the Chonos Archipelago. In the Arctic Ocean there are many large but unimportant islands.

The American continent consists of two principal parts, NORTH AMERICA and SOUTH AMERICA, which are connected by the narrow Isthmus of Panamá. These two bodies of land, though differing very much in climate and productions, are much alike in several respects. Each is of triangular outline, with the shortest side to the north, and with a narrow southern prolongation. In outline, North and South America have each a certain resemblance to Africa. The two Americas have each a high range of volcanic mountains, extending from north to south along the west coast, a broad central plain, and a relatively low eastern mountain-range. Their great rivers have also some features in common, especially in regard to their direction. Thus the La Plata recalls the Mississippi, the Amazon the St Lawrence; and the position and course of the Magdalena suggest comparison with the river Mackenzie. But there are some manifest points of contrast. North America has several large peninsulas, such as Labrador, Nova Scotia, Florida, Yucatan, Old California, Alaska, and others; while South America has no true peninsulas worth naming. North America sends to the Pacific four great rivers, the Yukon, the Fraser, the Columbia, and the Colorado; while South America pours but little water into the Pacific. Besides the three great South American rivers already named, there are the Orinoco, the São Francisco, the Rio Negro, and a few other considerable streams that flow directly to the ocean; while in North America we find the Saskatchewan, Nelson, Pembiscot, Hudson, Delaware, Susquehanna, Potomac, James, Cape Fear, Savannah, Mobile, Brazos, and several other important non-tributary rivers. There are also two great North American inland seas—Hudson Bay and the Gulf of Mexico; but nothing of the kind is seen in South America.

America is called the New World; and from the historical point of view, this name is obviously appropriate; but geologically it may be called the Old World, since the oldest known strata have their widest development on its surface; and there have been here found relics of prehistoric man, which must be regarded as among the oldest yet discovered.

NORTH AMERICA has (with water surface) an area of over 8,700,000 sq. m. It is larger than South America, which is in turn larger than Europe and Australia combined. Of the two great meridional lines of uplift, the western (that of the Rocky Mountains and their subsidiary chains) is vastly the greater, not only in height, but in breadth and length. From Alaska, in the NW., it extends throughout the Pacific coast-region. Near the two extremities volcanic activity is still great; but it is at present much more noteworthy in Central America than in Alaska. North of Mexico there is very little evidence of much very recent volcanic activity till we reach the Alaskan peninsula and the Aleutian Islands. Through those islands the volcanic chain makes a direct connection with the volcano-systems of Kamchatka, the Kuriles, Japan, Formosa, the Philippines, and the Malay Archipelago. Except those of the West Indies, all the active American volcanoes are found near the Pacific. There have, however, been severe earthquakes in the eastern section of the continent.

The western mountain-system of North America comprises a very great number of minor ranges, mostly having a north and south direction. The main chain (Sierra Madre) cannot be said to preserve an unmistakable identity throughout. The Coast Range, the Sierra Nevada, and the Cascade Mountains are the most noted of the western parallel ranges; they all lie on the Pacific slope, and they contain some of the highest of North American peaks. The elevated plateau called the Great Basin (chiefly in Utah and Nevada, U.S.), contains the Great Salt Lake and several smaller bodies of strongly saline water, evidently the remains of a much larger lake which once sent its waters to the sea; although at present the waters of the basin are all evaporated, its streams and lakes having no connection with the ocean.

The eastern or great Appalachian mountain-system has a general NNE. direction, nearly parallel with the Atlantic coast-line. Like the Brazilian mountains of South America, it is geologically much older than the corresponding western range; it is also far less elevated. The Appalachian Mountains begin at the south in the broken tablelands of Alabama. Through the Alleghanies, the Cumberlands, the Blue Ridge, and other parallel and variously named local ranges, they connect directly with the Catskills, the Shawangunk Mountains, the Helderberg Hills, and the Highlands of New York. Thence they continue NE. through the Green Mountains of Vermont to the Notre Dame Mountains and the Shickshock range of Eastern Canada. The mountains of Newfoundland, and the Watchish ridge of Labrador belong to the Appalachian system.

North of the St Lawrence River, the vast and complicated mountain-system of the Laurentides extends from the Atlantic to near Lake Superior, with a continuation into the Labrador peninsula. The Adirondacks are an outlying portion of the Laurentide system.

Since 1900 it has been found that the highest mountain in North America is neither any Mexican peak (as Orizaba), nor Mount St Elias (18,040 feet), nor Mount Logan (19,500 feet), but Mount McKinley (20,464 feet), in the heart of southern Alaska. In the Cascades are Mount St Helena, 15,750

feet; Mount Hood, 11,934 feet; Mount Takoma, 14,444 feet. In California, and chiefly in the Sierra Nevada, are Mount Whitney, 14,886 feet high; Mount Shasta, 14,440 feet; Mount King, 14,000 feet; Mount Tyndall, 14,386 feet.

From near Mount Brown and Mount Hooker, both reduced in 1898 from 15,500 to 9000 feet, flow the Saskatchewan, Mackenzie, Fraser, and Columbia Rivers. A group of lofty mountains in Central Colorado sends out the rivers Arkansas, Platte, Rio Grande, and Colorado. Among the highest mountains of Colorado are Mount Elbert, 14,436 feet high; Wilson, 14,280 feet; Lincoln, 14,297 feet; and Evans, 14,330 feet. A very large number are over 13,000 feet high. The highest point of the Alleghany system (Mount Mitchell) is only 6688 feet high. Mount Washington, in New Hampshire, reaches 6293 feet. Among the Adirondacks, Mount Marcy (5344 feet) is the highest. In Mexico, Popocatepetl reaches a height of 17,881 feet, while Orizaba is 18,206 feet high.

A remarkable feature of North America is the great central plain which reaches from the Arctic Ocean to the Gulf of Mexico. Its northern section is drained by the Mackenzie River; the central districts belong in part to the Saskatchewan-Nelson basin (whose outflow is to Hudson Bay), and in part to the St Lawrence system; while the southern half is mainly drained by the Mississippi. The only important break in the continuity of this great plain occurs in the Ozark Mountain region of Missouri and Arkansas. These mountains are low and irregularly disposed; they are connected by a low ridge with the Rocky Mountain system. A prominent feature of the central plain is the *Hauteur des Terres*, a high ridge, whence flow the Mississippi, the Red River, the St Lawrence, and the Winnipeg. This ridge is nowhere over 2000 feet high, and its ascent is extremely gradual. To the NE., however, there is a marked, though not very apparent slope towards the tidal waters of Hudson Bay. The general elevation of the central plain of North America is not very great. It is remarkable that to the eastward for a great part of its extent it is not bounded by any mountain wall, the western ridges of the Appalachian system sloping very gently to the westward, although their eastern faces are often steep and abrupt. The western half of the great valley is much higher than the eastern; and most of the foot-hill region east of the Rocky Mountains, like the valleys which intervene between the many mountain-ridges, has an elevation of from 5000 to 6000 feet. The Anahuac plateau ranges from 6000 up to 8000 feet.

The most general name for the great plains of North America is *prairie*; but in its present American use, the term has lost something of its original meaning in the French language, and acquired some new modifications. For the most part, the word designates a treeless plain; but there are local distinctions between *timbered* and *bald* or treeless prairies; and many plains at one time bare of trees have become well timbered through the operations of natural or other causes. There is little doubt that the former prevalence of great annual prairie fires was a principal cause of the absence of trees on the great plains. The settlement and cultivation of the country has greatly checked the spread of prairie fires; and, as a consequence, the timbered belts, which were formerly limited to the banks of streams, have in many places so spread as to cover a large proportion of the surface. The planting of forest trees, stimulated by bounties and by other favouring legislation, has been extensively undertaken, and in many places has succeeded beyond expectation. There is still a difference of opinion as to

whether tree-planting will ever increase the now insufficient rainfall of the high plains which border the Rocky Mountain region on the east. The prairies of North America vary much in respect of geological age, though very little of their area rests upon azoic strata. Few prairies are of a dead-level surface, and many are 'rolling'—that is, their surface is a succession of low wave-like swells and depressions. Often there are shallow ravines or *coulées*, which, like the wady-valleys of Arabia, may represent the courses of ancient streams. The plains often rise over the level of their rivers by a succession of 'benches,' or terraces, which in North-western Canada are mis-called *steppes*. Geographers have extended the North Asiatic term *tundra* to the marshy and sphagnum plains of sub-arctic America. In the extreme south, many of the grassy plains are locally termed *savannahs*; and along the Lower Mississippi and its delta are found the singular *prairies tremblantes*, or quaking plains, which shake beneath the tread. Many of these *prairies tremblantes* afford pasturage for herds, and some are crossed by lines of railway. It is believed that in such cases the lower strata are highly charged with water, while the surface is rendered firm by a network of roots, which in some cases is buoyed up by collections of marsh gas. In general, the true prairies have a very strong and tough sod; but after thorough ploughing, the surface becomes friable, and the soil generally proves highly productive. There are, however, prairies with a light and sandy soil, and with small agricultural capabilities. In other places, sand-hills and hard flinty ridges occur. Towards the Rocky Mountains, irrigation is generally necessary, and the grazing of cattle and sheep replaces, to a great extent, the operations of agriculture.

The coast-line of North America on the west is almost everywhere high and rocky. To the south of Puget Sound, good harbours are rare; but British Columbia and Alaska have great numbers of good seaports, the coast-line being, in many places, deeply cut with high-walled fjords, or 'canals,' and elsewhere sheltered by ranges of high and well-wooded islands. The Atlantic coast, to the north of New York Bay, is generally rocky and well sheltered with islands, and has abundance of good natural harbours; but south of the parallel of New York, the coast of the mainland is almost everywhere low and sandy. Many of the best ports are formed by river-mouths, and have sand-bars across their entrances. Nowhere else in the world is there any such extent of low and sandy coast as on the Atlantic and Gulf seaboard of the United States.

Hydrography.—The fluvial hydrography of North America is very remarkable. In general, Canada and the Atlantic slope are well-watered and have abundant rains. Along a narrow strip on the Pacific slope, from San Francisco southward to Acapulco, the water-supply is deficient, and the interior regions near the coast have locally a desert character; while from Acapulco southward the rainfall is ample for all needs. As will be seen further on, there is a marked analogy in this regard between the Pacific coast-region of North America and that of South America. The central valley is generally well supplied with water; but to the west of the Mississippi there are but scanty summer rains. As the Rocky Mountains are approached, the water-supply becomes more deficient; and, except where irrigation is practicable, agriculture proper generally gives place to the grazing of cattle. But in the Canadian part of the central valley there is ordinarily no deficiency of rainfall. In the Rocky Mountain region, the summers are generally very dry; and in some sections, irriga-

tion is required in order to produce crops. Still the great volume and length of the North American rivers, and the immense number of lakes, are sufficient proof of the amplitude of the general rainfall. In Canada, the lakes and rivers are especially numerous. It is stated that the St Lawrence, with its tributary lakes and rivers, contains one-half the fresh water of the globe. In the Rocky Mountain region of Canada, the great rivers, Yukon, Fraser, Columbia, Saskatchewan, and Mackenzie take their rise. Between these mountains and Hudson Bay, a girdle of vast lakes, or inland seas (Great Bear, Great Slave, Athabasca, Deer Lake, Winnipeg, and others), are seen to form a regular succession running from the Arctic Circle in a SSE. course to Lake Superior (350 by 100 miles), which is itself the largest fresh-water lake in the world, and the first of a wonderful chain of great sea-like expansions of the Upper St Lawrence. The line of these great lakes (from Great Bear Lake to the Lake of the Woods inclusive) marks the eastern limit of a fertile prairie region resting on fossiliferous rocks. East of this line we find a vast wilderness of 'Barren Grounds' and swamps, mostly unfertile, and geologically composed of azoic rocks. North of the St Lawrence system, almost the whole country is thickly studded with lakes, which, with their connecting streams, form a network of important water-ways traversable by canoes and boats. They nearly all swarm with valuable food-fishes, and many of the streams are capable of affording immense water-power. The river Saguenay is noted for the awful grandeur of its scenery. The Ottawa is the largest tributary of the St Lawrence, which is itself the largest in volume of North American rivers. Among the other large tributaries are the St Maurice, the Richelieu, the St Francis, and the Chaudière.

The Atlantic slope of the United States is well supplied with water, and many of its streams afford extensive navigation. The river Hudson, noted for its fine scenery, is remarkable as a deep tidal channel, affording the only naturally navigable water-way through the Appalachians. The Potomac is a river of notable character; and other important streams flowing to the Atlantic are the St John, the Penobscot, the Kennebec, the Merrimac (noted as affording more utilised water-power than any other river in the world), the Connecticut, the Delaware, the Susquehanna, the James, the Chowan, the Tar, the Neuse, the Cape Fear, the Great Pedee, the Santee, the Savannah, the Altamaha, and the St John's, nearly all navigable in their lower courses. The chief rivers flowing to the Gulf of Mexico are the Appalachicola, the Mobile, the Pearl, the great Mississippi, the Sabine, the Trinity, the Brazos, the Colorado of Texas, and the Rio Grande. The last-named river forms a part of the boundary between Mexico and the United States, and is the only very considerable stream of which any part is in Mexico, excepting the Colorado of the West (of which the mouth and lowest section are in Mexico), and the Santiago on the western slope. The United States portion of the great central plain is principally drained by the Gulf Coast rivers, and chiefly by the Mississippi (q.v.) and its great affluents. But a considerable part of this region has its outflow into the St Lawrence, through the great lakes; and in the north another area sends its waters to Hudson Bay, through the Nelson River. Along the crest or divide between these river-systems in Dakota and Minnesota, many lakes are found, some of them with no outlet. Of these last lakes, some are saline or brackish. Devil's Lake is the largest of these salt lakes.

Of the many large Alaskan rivers, the principal is the Yukon, which pours a vast flood into Behring (properly Bering) Sea. This is a channel of some steam-communication in summer. The Kuskokwim is another large stream of Alaska. The Fraser is a swift and strong river, flowing in a region of high mountains. The great river Columbia is noted alike for its navigation, its salmon-fisheries, and its enormous cataracts. The Rio Colorado, whose waters flow to the Gulf of California, traverses a desert plateau. Here, nearly every water-course runs in a deep-walled cañon—a narrow valley with precipitous sides, often of prodigious height. Many of the cañons are dry the greater part of the year. When rains occur, they wash the detritus of the rocky surface into the streams; and the swift waters, heavily laden with sharp sedimentary matter, act like a chisel in cutting away the bottoms of their own beds. In this way the cañons have been formed. The very aridity of the country has thus helped the process of cañon-formation, and of the consequent over-drainage of surface-strata. In a part of the Grand Cañon, the Colorado flows at a depth of 7000 feet below the general level of the country.

Climate.—The winter cold and the summer heat of North America seem, as a rule, to be extreme, when we consider the latitudes. Variations of temperature are more sudden and more extreme than in South America or Western Europe.

The arctic portion of North America has a climate of extreme severity; and much of the northern sub-arctic region has a decidedly arctic climate. Thus the Labrador peninsula is in the main a most forbidding and desolate expanse, covered with rocks and precipices, and having a winter far more rigorous and inhospitable than that of Lapland, or even Siberia. In the west, however, the corresponding region is nearly as mild as that of sub-arctic Europe; and Southern Alaska, at the coast-line, has very warm though rainy winters. Crossing the Rocky Mountains of Canada, we find the western half of the great central plain has not only a fertile soil, but a climate such that wheat can be grown even in the region of the Peace River; and it is asserted that the Mackenzie River valley is in part well adapted to cultivation, almost as far north as the Arctic Ocean. Yet the Barren Grounds west of Hudson Bay are altogether unfit for agriculture, and the same thing is true of much of the swampy and wooded region north of the Athabasca. But with every allowance, it remains certain that a large part of Western Canada is well adapted to the growth of barley, oats, and spring wheat of the first quality. The winters of this region are severe, but quite endurable; and it is their length rather than their severity that makes them dreaded by settlers. In that part of Western Canada which is crossed by the Canadian Pacific Railway, and extends northward in the valleys of the Red, Saskatchewan, Athabasca, and Peace Rivers, agriculture has of late years greatly developed, wheat being the great staple, and a large number of farmers have been attracted to this region. As a result, Canada promises to become one of the leading wheat countries of the world.

The spring-wheat belt extends for several degrees south of the Canada-United States boundary; and it is succeeded by the winter-wheat belt. Here maize becomes the leading cereal, and continues so southward through Mexico and Central America. The other cereals grown in the United States are much the same as those ordinarily produced in Europe. The sugar-beet is increasing in cultivation, the sugar-cane being raised only in the most southern parts of the United States, and in lati-

tudes still farther south. Tobacco is an important crop not only in tropical America, but nearly as far north as Canada. Cotton reaches its northern limit in California, Missouri, and Virginia. True rice is grown in the more southern United States; and an interesting though uncultivated native cereal called 'wild rice' (*Zizania aquatica*) grows in various parts of North America, and in some places its seed is extensively collected by the Indians. Throughout the Atlantic and Gulf slopes of North America, the winter climate is much more severe than in corresponding European latitudes. It will be observed that nearly all the cultivated crop-products of North America (except maize, potatoes, and tobacco) are of Old-World origin. The same thing is true in a less degree of the cultivated fruits. The European apple thrives even better in North America than in Europe; so likewise do the peach, the pear, and other fruits. But the grapes generally cultivated in America are of native or hybrid origin; although the European grape does well in California and Mexico. The cranberries, strawberries, and some of the other cultivated small fruits of North America, are of native origin, as are some of the more hardy varieties of the plum. Sub-tropical fruits, such as the orange, fig, and lemon, do well in that limited part of non-tropical North America which lies south of the frost-line.

Geology.—The geology of North America is a subject of much interest. The Laurentides and Adirondacks are composed chiefly of azoic rocks of remote geologic epoch. In the New England States, granitic and gneissoid rocks are very common, and injected dykes of very ancient date are abundant. Where palæozoic rocks are found in this region, they are often highly metamorphic. In no part of the world are evidences of glacial action more extensive or more interesting than in the northern two-thirds of North America. Throughout the Appalachian region, Silurian, Devonian, and Carboniferous strata are found, ranging from Newfoundland SSW. to Alabama; and coal-bearing strata are largely developed from Pennsylvania southward. Limited areas of coal occur in Newfoundland, Nova Scotia, and Massachusetts. West of the Alleghanies, true coals occur in most of the United States east of the Mississippi. But the coals of North Carolina, and some in Virginia, are Triassic. Nearly all the coals of Mexico, of the Pacific States, of the Rocky Mountains, and of the North-western Canada region, so far as is now known, are of either Tertiary or Cretaceous age. Though classed as lignites, many of them are excellent steam-coals, and some of them coke well, and are very serviceable in smelting operations. Strata belonging to nearly every recognised geologic period are discoverable in North America.

It is believed that a considerable share of Eastern Canada, together with a great part of the New England states, occupies the site of two or more large islands which together formed the most extensive surface development now existing of the oldest sedimentary rocks. Similar islands probably existed at various points along the great western Cordillera, both in North and South America, as well as in the West Indies, Guiana, and Brazil; and the building of the continent was essentially a process of extension, through which the spaces intervening between the various island-groups were converted into land. Enormous growth of the land areas was made during the Silurian period, and still greater before the close of the Devonian and Lower Carboniferous times. There is no doubt that the coal measures of North America, richly as they are now stored, were once much richer than at present. Glaciers have ploughed into the great coal-beds, torrents and floods have stripped large

areas of the underlying rocks of their coaly covering, and the heat and pressure of injected dykes have graphitised some beds and burned up others. The greater part of the present Appalachian system of ridges and folds did not exist except in embryo, until about the close of the Palæozoic era. The great central plain of North America must have been mainly occupied by shallow seas even as late as the Cretaceous period, the strata of which, extensively developed to the east of the Rocky Mountains, have yielded the remains of many gigantic saurians, as well as of those wonderful toothed birds (*Odontornithes*) which have of late attracted the notice of naturalists everywhere. The Cretaceous seas seem to have been in great part converted into a land-surface before the beginning of the Tertiary period. But after the Cretaceous epoch had closed there remained great lakes and marshes, in the beds of which are now found remains of many wonderful mammalian forms. From the Miocene downwards, edentate remains, often of large-sized animals, are abundantly found in North America, although at present there are only a few living species known. Professor O. C. Marsh believes that North America is the original abode of the edentates. Far less abundant, though still plentiful, are remains of rodents. Various species of elephants also existed. The entirely extinct amblypod mammals were apparently peculiar to North America. Tapiroid, camel-like, and other mammals in great variety have left their bones in the Tertiary strata of the continent. The American species of rhinoceros probably became extinct before the end of the Pliocene time. The equine remains include some which may be regarded as relics of true horses; and it is supposed that the introduction of horses from Europe to America was simply a restoration of the species to its original habitat.

The Rocky Mountain region, in its present shape, is of much later geologic age than the Appalachian country. Vast lava-fields occur, and there are numerous craters of volcanoes not long extinct. The most powerful of known geysers, or intermittent thermal springs, occur in North America, chiefly in the Upper Valley of the Yellowstone River. Iron is abundantly developed in the Laurentides and in the Appalachians, and ores of a great variety of grades occur in almost every part of North America. The Lake Superior region and the state of Missouri are especially rich in iron ores. Some of the Cuban ores are of especial excellence. The states of Pennsylvania, New York, Ohio, Tennessee, and Alabama are prominent as seats of the iron industry.

Gold has been largely obtained from Mexico and Central America, from the Pacific slope and the Rocky Mountain region, from the Black Hills of Dakota, and from many places about the Appalachian range, and from Alaska and the neighbouring Yukon region. Silver ores are richest in Colorado, Nevada, and Utah; but argentiferous galena is widespread, occurring from Newfoundland, Eastern Canada, and Maine, to Mexico and to Lake Superior. Lead is largely produced in the silver regions, as also in Missouri, Iowa, Illinois, and Wisconsin. Petroleum has a rich development in Western Pennsylvania, and the adjacent districts of other states; also in Texas, Oklahoma, and California. The celebrated wells of *natural gas*, chiefly in Pennsylvania and adjacent states, have afforded valuable fuel to iron-works and other industrial establishments. The asphalts of Cuba are reported to be rich, but they are surpassed in value and availability by those of the island of Trinidad and the adjoining region of Venezuela. Salt is found extensively in Ontario, Michigan, New York, Louisiana, and the Great

Basin. The copper of Lake Superior and of Arizona is of very high importance.

Natural History.—The zoology of North America is rich and varied. Here occur the bison (nearly extinct of late), the musk-ox, the Rocky Mountain sheep, two antelopes (the pronghorn and the Rocky Mountain goat, the former remarkable as the only antelope with branched horns, and the only one known to have deciduous horns), the reindeer, the elk or moose, the wapiti and several other deer, five species of bear, the walrus, sea and river otters, fur and hair seals, wolves and foxes of various species, the beaver, several hares, the raccoon, the marten, mink, and skunk, two or more marmots, a true polecat, a badger, the wolverine, and a large number of minor fur-bearing and other mammals. There is only one marsupial found—the opossum. Of feline animals, the puma and lynx are the most widely diffused; the jaguar and ocelot are found in the warmer latitudes, where occur the peccary, and even the tapir and other South American forms. Tropical North America has not nearly so many species of the monkey tribe as occur in South America. In Mexico and Central America, there are found many animals of distinctly South American type. The avi-fauna is singularly rich. All the humming-birds are strictly American; but the North American species are far less numerous than the South American. The vultures of America are entirely distinct in structure, though not in habits or appearance, from the old-world species. Many American birds are very rich in plumage; the song-birds, as a rule, are more remarkable for sweetness and delicacy of note than for volume of sound. A very large proportion of the known species of tailed batrachians are North American. Of the animal kingdom, it is believed that North America has afforded only one native species now truly domesticated—viz. the common turkey. The native tropical American fauna is one of the richest and most strongly marked anywhere known. Among reptiles, we find the rattlesnakes (some of which are South American). The 'Gila Monster' (*Heloderma horridum*) is the only venomous lizard known in any part of the world. There are many valuable food-fishes occurring in the rivers and seas.

The flora of North America has strong marked features of distribution. The plants of the far North belong in many instances to species which are natives of Europe also. The flora of the Atlantic States has many species and genera in common with that of Eastern Asia. Many of the Atlantic species are remarkable for an extensive range north and south, which persists in spite of great local differences of climate. The West Indian flora (essentially South American) would appear to have only of late invaded peninsular Florida, along the southern shores of which it has established itself to a remarkable degree. Westward, the highlands of Mexico seem to have acted as a barrier against the northward spread of tropical forms. North America abounds in great forests of valuable timber-trees in great variety. Most of the trees are congeneric with European timber-trees; but only a few arboreal species are found alike on both continents; neither are there many species found on both sides of the Rocky Mountains. The dense forests of the Pacific slope are largely made up of coniferous trees, mostly of species not known on the Atlantic slope. Mahogany, logwood, and lignum-vitæ are extensively produced in the tropical section. Since colonisation began, a very great number of European plants, chiefly grasses and weeds, have naturalised themselves in the country. Of cultivated North American native plants, we may specify tobacco,

maize, the common potato (perhaps originally South American, as the tomato is), cacao, vanilla, and some species of melons; also gourds, beans, capsicum, and indigo.

Ethnology.—The native peoples of North and South America alike would appear to have been all of one race, although the Eskimo of the far North resemble the 'Indian,' or copper-coloured native races, not so much in appearance and in physical features, as in the polysynthetic or incorporative character of their system of word-building. This polysynthesis differs in kind as well as in degree from the agglutination observable in so many North Asiatic languages. It has indeed no exact counterpart in any Old-World tongue, but something resembling it is seen in the language of the Basques. The polysynthetic languages have, as a rule, very long words, or combinations, which in fact represent sentences rather than words. The number of native languages and dialects is very great indeed; and in such languages as have received no alphabetic standard, the vocabularies and pronunciation of words are subject to continual changes. Further notice of the red men and of their ancient centres of semi-civilisation is contained in the article AMERICAN INDIANS.

The present population of North America contains a copious element of the Indian stock, chiefly found in the remoter parts of Canada and in Mexico and Central America. In Spanish America and in Manitoba (Canada), there are many persons of mixed white and Indian origin. The Spanish language is spoken in Central America, Mexico, Cuba, and Puerto Rico; French prevails in parts of Canada and Louisiana, and in some of the West Indies; and a German dialect prevails locally in Pennsylvania. But by far the largest share of the North American people are English in language, if not in descent.

Antiquities.—In addition to the facts cited in the article AMERICAN INDIANS, it may not be amiss to notice here certain geographical areas noteworthy for some peculiarities in respect of their archaeological remains. It may be said in advance that most of the more modern authorities reject the theory that the interesting earthworks and other remains of remote antiquity in America are to be ascribed to a race of 'mound-builders' distinct from the present stock of Indians. The fact that the semi-civilised peoples of Arizona and New Mexico have plainly and unmistakably the same general characters as the other aboriginal races seems decisive on this point. The works of the 'mound-builders' are chiefly found in the Ohio and Mississippi valleys; but examples are to be met with at least as far north as Winnipeg. Those of Wisconsin are frequently built upon a ground-plan evidently designed to imitate the form of some animal, as the tortoise, serpent, bear, or even man.

Farther south they are generally pyramidal or conical, and most of them truncated. They are usually of earth, or of earth and stone. Many are clearly sepulchral, others apparently designed for sacrificial or other religious purposes, and a few seem like fortifications. Not infrequently the mounds proper are inclosed by square, circular, or polygonal earthworks, often very regular in outline. The sepulchral mounds often contain human remains, as well as weapons and utensils of stone, bone, or native copper. The style of art here observed is, for the most part, decidedly that of the existing North American tribes. Yet the mounds indicate a degree of persistent labour not to be expected of savage tribes, and suggesting a condition of organisation superior to that found among the northern Indians. In many instances the mounds are overgrown with large trees, and there is no doubt that many are of great age; but, again,

there are mounds which, according to the traditions of settlers, were built within the historic period; and to some of these a fixed date is assigned in local annals. This, however, is open to doubt.

The now unpeopled cliff-dwellings of the Arizona cañons recall the similarly-situated prehistoric houses of the Balearic Islands, and the cliff-towns of the island of Thera (Santorini) in the Aegean, which last are still inhabited. When the Spaniards conquered Central America they found cañon towns with many inhabitants. Certain loftily-built mesa-towns (like Acoma, in New Mexico) are entirely paralleled by such places as Albinen, in Switzerland, which is only accessible by means of a succession of wooden ladders. There is, however, reason to assign to many ruined North American towns a very high antiquity, since the irrigation-works which sometimes are found near them could not have been available or useful except in times when the climatic conditions were very different from what we observe at present in those arid regions.

The far more remarkable architectural remains of the old Mexican, Peruvian, and Nicaraguan civilisations are noticed under the names of their respective countries. Perhaps independent of all these was the very noteworthy advancement of the Chibcha race in Colombia.

Political Divisions.—The political divisions of North America are (1) Danish America—that is, Greenland. Three small islands of the Virgin group were sold to the United States in 1916-17. (2) British North America—the Dominion of Canada, Newfoundland, Labrador, the Bermudas, the numerous British West Indian islands, and British Honduras. (3) The United States, including the detached territory of Alaska. (4) Mexico. (5) The Central American republics of Honduras, Guatemala, Salvador, Nicaragua, and Costa Rica, together with part of the republic of Panamá, the rest of which is on the South American side of the Isthmus of Panamá. (6) The West Indian republics of Cuba, Hayti, and San Domingo. (7) The Dutch West Indies. (8) Colombian islands (see below: SOUTH AMERICA). Some of the West Indian islands are more South American than North American in character. See table near the end of this article.

The population of North America is over 130,000,000, of which probably 6,000,000 are of pure or mixed Indian descent. The very great majority of North American Indians are found in Mexico and Central America. The people of African stock number at least 10,000,000, most of whom are natives of the United States. The original slave element was derived from almost every coast-region of the African continent.

Colonisation.—The original colonisation of North America, so far as Great Britain was concerned, was for the most part a true *emigration*, by families, and was chiefly voluntary; although Great Britain, as well as several other European countries, both before and after the American Revolution of 1776, shipped many convicts and paupers to America. The immigration from England and Scotland has mainly fixed the type of civilisation alike in the United States and in Canada. The French colonisation was a very different affair, carried on largely at the public expense, and receiving the fostering care of church and state alike. Spanish colonisation was to a great extent the work of adventurous persons, bent on the acquirement of fame and fortune in the gold-fields. The Dutch settlements were almost purely commercial in their spirit. The large and early German immigration was, in a great degree, the movement of members of Protestant dissident sects to a land of religious liberty; even more largely was it a result of the Franco-German wars of the 18th century, leading to the wholesale

expatriation of the people. Irish immigration began as early as Cromwell's time, and was at first in part compulsory. After the year 1845 it immensely increased in volume. The newer German movement to America grew to be a very large one. Many thousands of Scandinavians have in recent years found homes, chiefly in the northern part of the Mississippi Valley. There has also been a large and quite recent Slavic influx, chiefly Polish, Czech, and Yugoslav, to North America. (See also DUKHO-BORTZI.) Italy, too, is sending out many settlers, chiefly of the humbler labouring classes. The so-called Hungarian element has been largely introduced on labour-contracts, which often provide for the return of the labourer, after a fixed time, to his own country. This system is liable to many abuses, and in the United States its exercise is forbidden by law. The introduction of Chinese labour, on a similar contract-system, was not long since very prevalent; but that practice is also illegal in the United States.

North America has for more than two centuries been the principal objective point for European emigration. This has been chiefly directed to the United States, where public lands have been sold on the most liberal terms, or given to actual settlers. As a consequence, the amount of public land suitable for agriculture has become greatly reduced; but there are still large tracts of land owned by the railway companies and capitalists, and offered for sale to immigrants at very reasonable rates. Since the overthrow of the slave system in the Southern States, that section has attracted many settlers. In Canada there are still vast and unoccupied areas of fertile soil available for settlement. Mexico has much unoccupied territory, but its climate and social conditions render it less attractive to immigrants from the north than to those from the south of Europe. For the former, the United States and Canada are more suitable, since for the most part no process of acclimatisation has to be gone through. European immigrants, as a rule, live out the full term of their years in North America, and life-insurance tables assign a longer probable term of life to Americans than that agreed upon by European insurance companies. The diseases the immigrant has to encounter are much the same as those of Europe. Pulmonary consumption is common in the Atlantic States, especially in places where the soil-moisture is great and changes of temperature frequent and extreme. Malarial fevers prevail in many newly settled districts, and in places having alluvial soils. Fevers and intestinal troubles appear to prevail more extensively in southern than in northern latitudes. There are theorists who hold that the European race in North America must decline in vigour and in physical and mental strength; but the facts, so far as known, do not appear to warrant any such opinion.

The intermarriage of white persons of different national origin may ultimately lead to a modification of the now familiar American type of figure and feature. The American of European descent is often spare and even delicate in outline, and slightly taller, on the average, than his European relative. Activity and quickness are common mental and physical attributes. Mechanical invention is a field in which American enterprise has greatly distinguished itself. The struggle for wealth and for material success is intense in North America, and as a consequence intellectual pursuits, literature, and the fine arts have had less encouragement here than in some of the mother-countries. Nevertheless, popular education is nowhere better provided for than in the United States and Canada. Institutions for the higher education.

are numerous, and many of them are well endowed and highly efficient. What may be called the American branch of English literature is already noteworthy for the volume, and for the increasing value of its outcome, the tendency being towards a higher standard of literary merit. In science, the American mind has very naturally been turned towards practical rather than theoretical work; yet, even in pure science, much excellent work has been done in America.

It may be added that the prejudice which undoubtedly exists in some parts of Europe regarding all things American has led, and does still lead, some critics to minimise and undervalue American science and literature. It may be confidently asserted that life in the New World is neither so sordid and materialistic as hostile critics would have the world believe, nor yet so ideally perfect as mistaken patriotism might claim. It may be further said that the poor man, as a rule, has a happier and more hopeful lot in America than he can have in an old country, where social conditions are long established and comparatively unyielding.

It is stated by many observers that in Mexico and Central America the Indian element is gaining upon the white, and that the 'Ladino' (half-breed, or mixed) element is becoming more and more Indianised. Such statements should be received with caution, since trustworthy census reports are entirely wanting. It is certain, however, that in recent years there has been a marked decline in the number and extent of those civil wars which have formed such a prominent feature in Spanish-American life. Railways have also met with great extension, and there is a strong movement for the introduction of popular education, and the development of material resources. Brigandage and assassination have also been much repressed. The quiet and uneventful life of these countries in time of peace seems, to a traveller of northern origin, a proof of the indolence and lethargy of the people. The pursuits of the natives are pastoral rather than agricultural; and their manner of life is at once oriental and medieval—oriental in its dreamy, aimless, and leisurely methods, and medieval in the lack of public feeling of the people generally, as much as in their simple credulity, and their unquestioning charity towards the poor.

The details of the agriculture of North America, as well as those of its manufacturing and mining interests, its canals, railways, and telegraphs, are more fully noticed under the heads of its respective states, especially in the articles on the United States and Canada. About nine-tenths of North America is in what is called the temperate zone, though we have seen that a considerable share of this region has an arctic climate. In like manner, a considerable part of tropical North America has a temperate, or even a cool climate. This is especially true of the plateaus of Anahuac and Oaxaca in Mexico, where the altitude is such that the temperature is singularly cool and equable, though the country suffers from drought. The region properly called *Central America* is the high mountainous body of land between the Isthmus of Panama and that of Tehuantepec. This part of the continent is very humid, but most of it is so high as not to have a very hot climate; and on the eastern coast the strong and steady trade-winds not only moderate the heat, but render the low and marshy coast remarkably healthful for a tropical region. The West Indies are subject to terrible hurricanes; the interior of North America is often visited by destructive tornadoes.

SOUTH AMERICA has much the same general shape on the map as North America, and the semi-continents have many features in common, as well as certain marked contrasts. The broadest part of

each is towards the north; but the northern portion of North America is a frozen and most repelling region, having its coasts washed by a trackless frozen ocean, filled with barren and ice-crowned islands; while the Caribbean Sea, which lies north of the southern half of the continent, is entirely tropical, and is encircled by a chain of rich and beautiful islands, where frosts are never seen. The climates are therefore reversed. The greater portion of North America has either a cold or a temperate climate; while that part of South America which is of corresponding position and importance has a hot climate. The tropical region of North America is relatively small in area; while in South America it is much the smaller part which has a cold climate. Moreover, the winter cold of Patagonia, Fuegia, and the Falkland Islands is never extreme, like that of so great a part of North America. Even Fuegia, which has a terribly bleak and blustering windy climate, is never very cold. The summers of the extreme south of America are indeed relatively cold, but the winters are correspondingly mild; that is to say, the climate is more steady and less changeable than that of North America. The summers of the Falkland Islands are certainly much cooler than those of London, which has a corresponding north latitude; but the Falkland winter is not much colder than the summer. In short, the climate is chilly rather than cold, and damp rather than wet (for the rainfall, though almost continual, is really small).

The Andes, or South American Cordilleras, have some features in common with the great North American Cordilleras, the Rocky Mountain system. They both extend north and south; both are near the west coast; both are volcanic; and both cut off the rains from a considerable region, rendering the climate locally very dry. But the Andes are much more nearly continuous; they are a much more complete barrier to the traveller and merchant, as well as to the rain-bearing winds of the Atlantic; they have a much greater absolute height, and contain a far greater number of very lofty peaks. Their volcanic activity is also at present much more intense than is seen at any point in North America north of the Tehuantepec Isthmus. The dry or desert region west of the Andes is far more extensive and far more completely arid than the corresponding section of North America. The Andes, for a great part of their course, are disposed in two or three somewhat closely parallel chains, running near each other. In Bolivia and Peru they inclose the land-locked plateau of Lake Titicaca. Towards the north, in the republic of Colombia, a high and rugged chain runs off to the north-east and east, forming the coast-mountains of Colombia and Venezuela. South of the Orinoco and north of the Amazon lies the great quasi-peninsula of Guayana, a mountainous region, only a small part of which is well known to geographers.

The mountains of Brazil have been likened to the Appalachians of North America, which they resemble in having an eastward situation. But, unlike them, they have no marked regularity in course, or uniformity of character. The main system seems to divide the Amazon basin from that of the La Plata, sending branches out to the north, so as to separate from each other the various basins of the main Amazonian tributaries. An elongated ring or ellipse of mountains encircles the great valley of the river São Francisco, and another range, the Serra do Mar, runs near the east coast. Farther west is the Serra Mantiquiera, regarded as the main chain of the Brazilian mountains; while the watershed between the north and the south flowing streams is called the Serra dos Vertentes. Barely one-fifth of Brazil is truly mountainous. In

point of geologic age, the Brazilian mountains are much older than the Andes. They are largely made up of gneiss and gneissoid rocks. The Guayana mountains much resemble them. To the east of the Andes, and as it were reclining against them, there is an enormous and lofty plateau on which are scattered various extinct or dormant volcanic peaks; but the western slope of the Andes is usually very steep. In some parts of the eastern sub-Andean plain there appear complicated (but generally north and south) ranges of lower mountains, occasionally sending out an arm of hills into the plains of the interior. The really temperate part of South America, including most of Chile, Uruguay, and the Argentine Republic, has a mild, and for the most part singularly equable and agreeable, climate; although Northern Chile is a hot and arid desert, and the southern third of that country, including the Chonos Archipelago, is drenched with continual rains. The greater and most characteristic region of South America is the tropical portion. For a tropical country the climate is in general remarkably fine, regular, and healthful. A marked feature is the large and regular rainfall, caused by the Andes, which here stand exactly across the course of the trade-winds. These winds, carried gradually upwards by the shelving plateaus, till they reach the cold Andean summit-region, precipitate nearly all their moisture, and leave the narrow strip of land west of the Andes a desert. Towards the north and south, the Pacific slope, being out of the highway of the trade-winds, receives abundant moisture from the Pacific. Owing to the enormous rainfall of tropical South America, it is above all others the land of great rivers. The three great river-systems of the Orinoco, the Amazon, and the Plata are all primarily developed upon the eastern terraces of the Andes; but the Plata derives its main water-supply from the Brazilian mountains. Other large rivers are the Magdalena in Colombia, the São Francisco in Brazil, and the Rio Negro in the Argentine Republic. Among the tributary branches of the three great rivers there are many streams which for length and volume take rank with the world's largest rivers. South America has few large lakes, Lake Titicaca being one of the most remarkable; but the slopes of the Southern Andes abound in smaller lakes, doubtless of glacial origin. The lake of Maracaibo, in Venezuela, is a landlocked and tideless gulf or arm of the sea.

The interior of South America presents considerable variety. In the central and southern portion of Venezuela we find extensive steppes or prairies, here called llanos; an open region, in part treeless, but in general grassy and devoted to pasturage. To the east and west of these the country is for the most part densely wooded. The vast forest-clad plain of the Amazon is of fluvial origin; and although the river is said to have no true delta, the inland forest through which its waters flow may be said to be of the true delta formation, being everywhere cut by spill-channels and creeks which derive their water from the main river. These channels, together with the Amazonian tributaries, afford in the aggregate a vast, and thus far uncomputed extent of inland navigation. The land portion of this whole region is closely forested, and in extent, density, and average height of trees, it is probable that its woodlands have no rivals in any part of the world. In the more central and elevated parts of Brazil, leaving the wooded river-valleys, we find a vast extent of open grassy plains, or campos, crossed with granitic ridges. Towards the southern tropic we encounter a region which, though little developed, appears to be one of the finest and most fertile on the globe.

Farther south the forests begin to disappear, and finally end in the great treeless pampas of the Argentine Republic. It may be remarked that, even in the equatorial region, the high valleys and plains of the Andes enjoy a wonderfully mild and agreeable temperate climate, while the higher mountain-slopes have a perpetual winter. Between the Argentine pampas and the forest region to the north, is the vast wilderness of the Gran Chaco, where strips of forest intervene between grassy plains and dry scrubby ridges. Some of the lower plains are subject to overflow in the rainy season. The Patagonian region south of the pampas consists largely of a succession of terraces rising westward to the Andes, and crossed by many swift and copious rivers. Here are seen vast fields covered with loose stones and shingle, recalling the enormous boulder-covered waste of Labrador. Almost equally remarkable are the 'stone-rivers' of the Falkland Islands—long valleys nearly filled with loose stones. Farther south lies the Fuegian Archipelago, a gloomy and unpleasant region with a bleak climate. Large areas of the islands are densely wooded, and much of the surface is broken and precipitous. Not only is the Andean region in many parts full of active volcanoes, but the country near it is to a singular degree liable to earthquakes, which are of special frequency in Chile, Peru, Ecuador, and Venezuela; and at some points on the Chilean coast the earth is said to be constantly shaken by earth-tremors.

The *mineral wealth* of South America is very great. The gold, silver, copper, mercury, and other valuable metals of Peru have given it a proverbial, though really undeserved, reputation for wealth. The desert country on the Chilean coast is rich in nitre (nitrate of soda), valuable iodine compounds, and borax. Its guano, formerly abundant, is now nearly exhausted. The copper and silver of Chile have been a great source of wealth; and its coal, though not of the Carboniferous period, promises to become of very high importance. Bolivia contains the celebrated silver-mines of Potosí. Venezuela and Guiana afford considerable supplies of gold; and very rich discoveries of the same metal have been made in Patagonia. Coal occurs in Brazil, and at various points southward. It is mined on the north shore of the Strait of Magellan. Brazil is celebrated for its diamonds.

The *plant-life* of South America is singularly rich and varied. Potatoes, maize, tobacco, pine-apples, vanilla, cacao, and tapioca are all considered to be native American, and probably South American products. Among native medicinal plants are numerous species of trees whose barks yield quinine. Ipecacuanha, coca, copaiba, sarsaparilla, and jaborandi are among the many native drugs. The forests yield india-rubber, rosewood, divi-divi, Brazil nuts, and maté or Paraguay tea. Here grow the cow-tree and a large number of species of forest trees affording ornamental and cabinet woods. The plant-life of the tropics is redundant; and the forests are often so dense and so entangled with woody vines as to be impenetrable. In South America the flora is essentially a tropical one, varying much from the Old-World type. There are some plants which are common to North America, but these would seem to have been propagated along the high western sierras. The flora west of the Andes, especially in the far south, is very distinct from that of the main body of the continent, and has quite a number of genera and species in common with Australia, New Zealand, and South Africa, and even with Southern Asia.

The *native animals* of South America are of many species. Except the dog, the llama and alpaca are believed to be the only native species of mammals ever truly domesticated by the American

Indians. Both of these, with the vicuña and guanaco, are of the camel tribe. The llama is used to some extent in Peru as a beast of burden. It also affords wool, but not of so fine quality as that of the alpaca. Among the wild beasts of prey are bears, pumas, jaguars, ocelots, and several kinds of wild-cat. Foxes, skunks, raccoons, otters, the nutria or coypu, and several species of deer are known; as also several remarkable rodents, among them the agouti, the cavies, the capybara, the chinchilla, the viscacha, and some porcupines. The monkeys are of a great many species, all remarkably distinct from those of the Old World. South America is the home of most of the living species of edentates, such as the sloths, armadillos, and true ant-eaters. Here also are found several species of marsupials. Other animals are the vampire bats, tapirs, peccaries, &c. Among the great serpents are the anaconda and the boa-constrictor. The venomous species include rattle-snakes, coral-snakes, and the dreaded bushmaster or lachesis. The birds are of extremely numerous species, and many are of wonderful brilliancy. Among them are the condor, the rhea, the toucan, and countless parrots and humming-birds. The fishes and insects are vastly numerous, both in individuals and species. The mammalian remains of the tertiary and quaternary strata of South America are scarcely less interesting than those of North America. The Palæotherium and Anoplotherium; the huge edentate Glyptodon and the ground-sloths (among which is the enormous Megatherium)—these are among the interesting extinct South American mammalian genera, of which as a whole our knowledge is as yet very imperfect.

The *agricultural capabilities* of a large part of South America are unquestionably very great. Stock-breeding is the leading industry on the pampas of the south, and on the llanos and campos of the north. Coffee-growing is a prominent pursuit in Brazil. The cereal grains thrive remarkably in the temperate regions. Sugar, tobacco, and cotton are produced in the warmer latitudes. Silver, copper, iodine, nitrates, guano, hay, and provisions are shipped from the west coast. From the La Plata countries wool and various cattle products are very important exports. Wheat is raised and shipped in rapidly increasing quantity. Peruvian bark and other medicines, rubber, cabinet-woods, chocolate, tobacco, and fruits are shipped from the tropical and forest regions of the north.

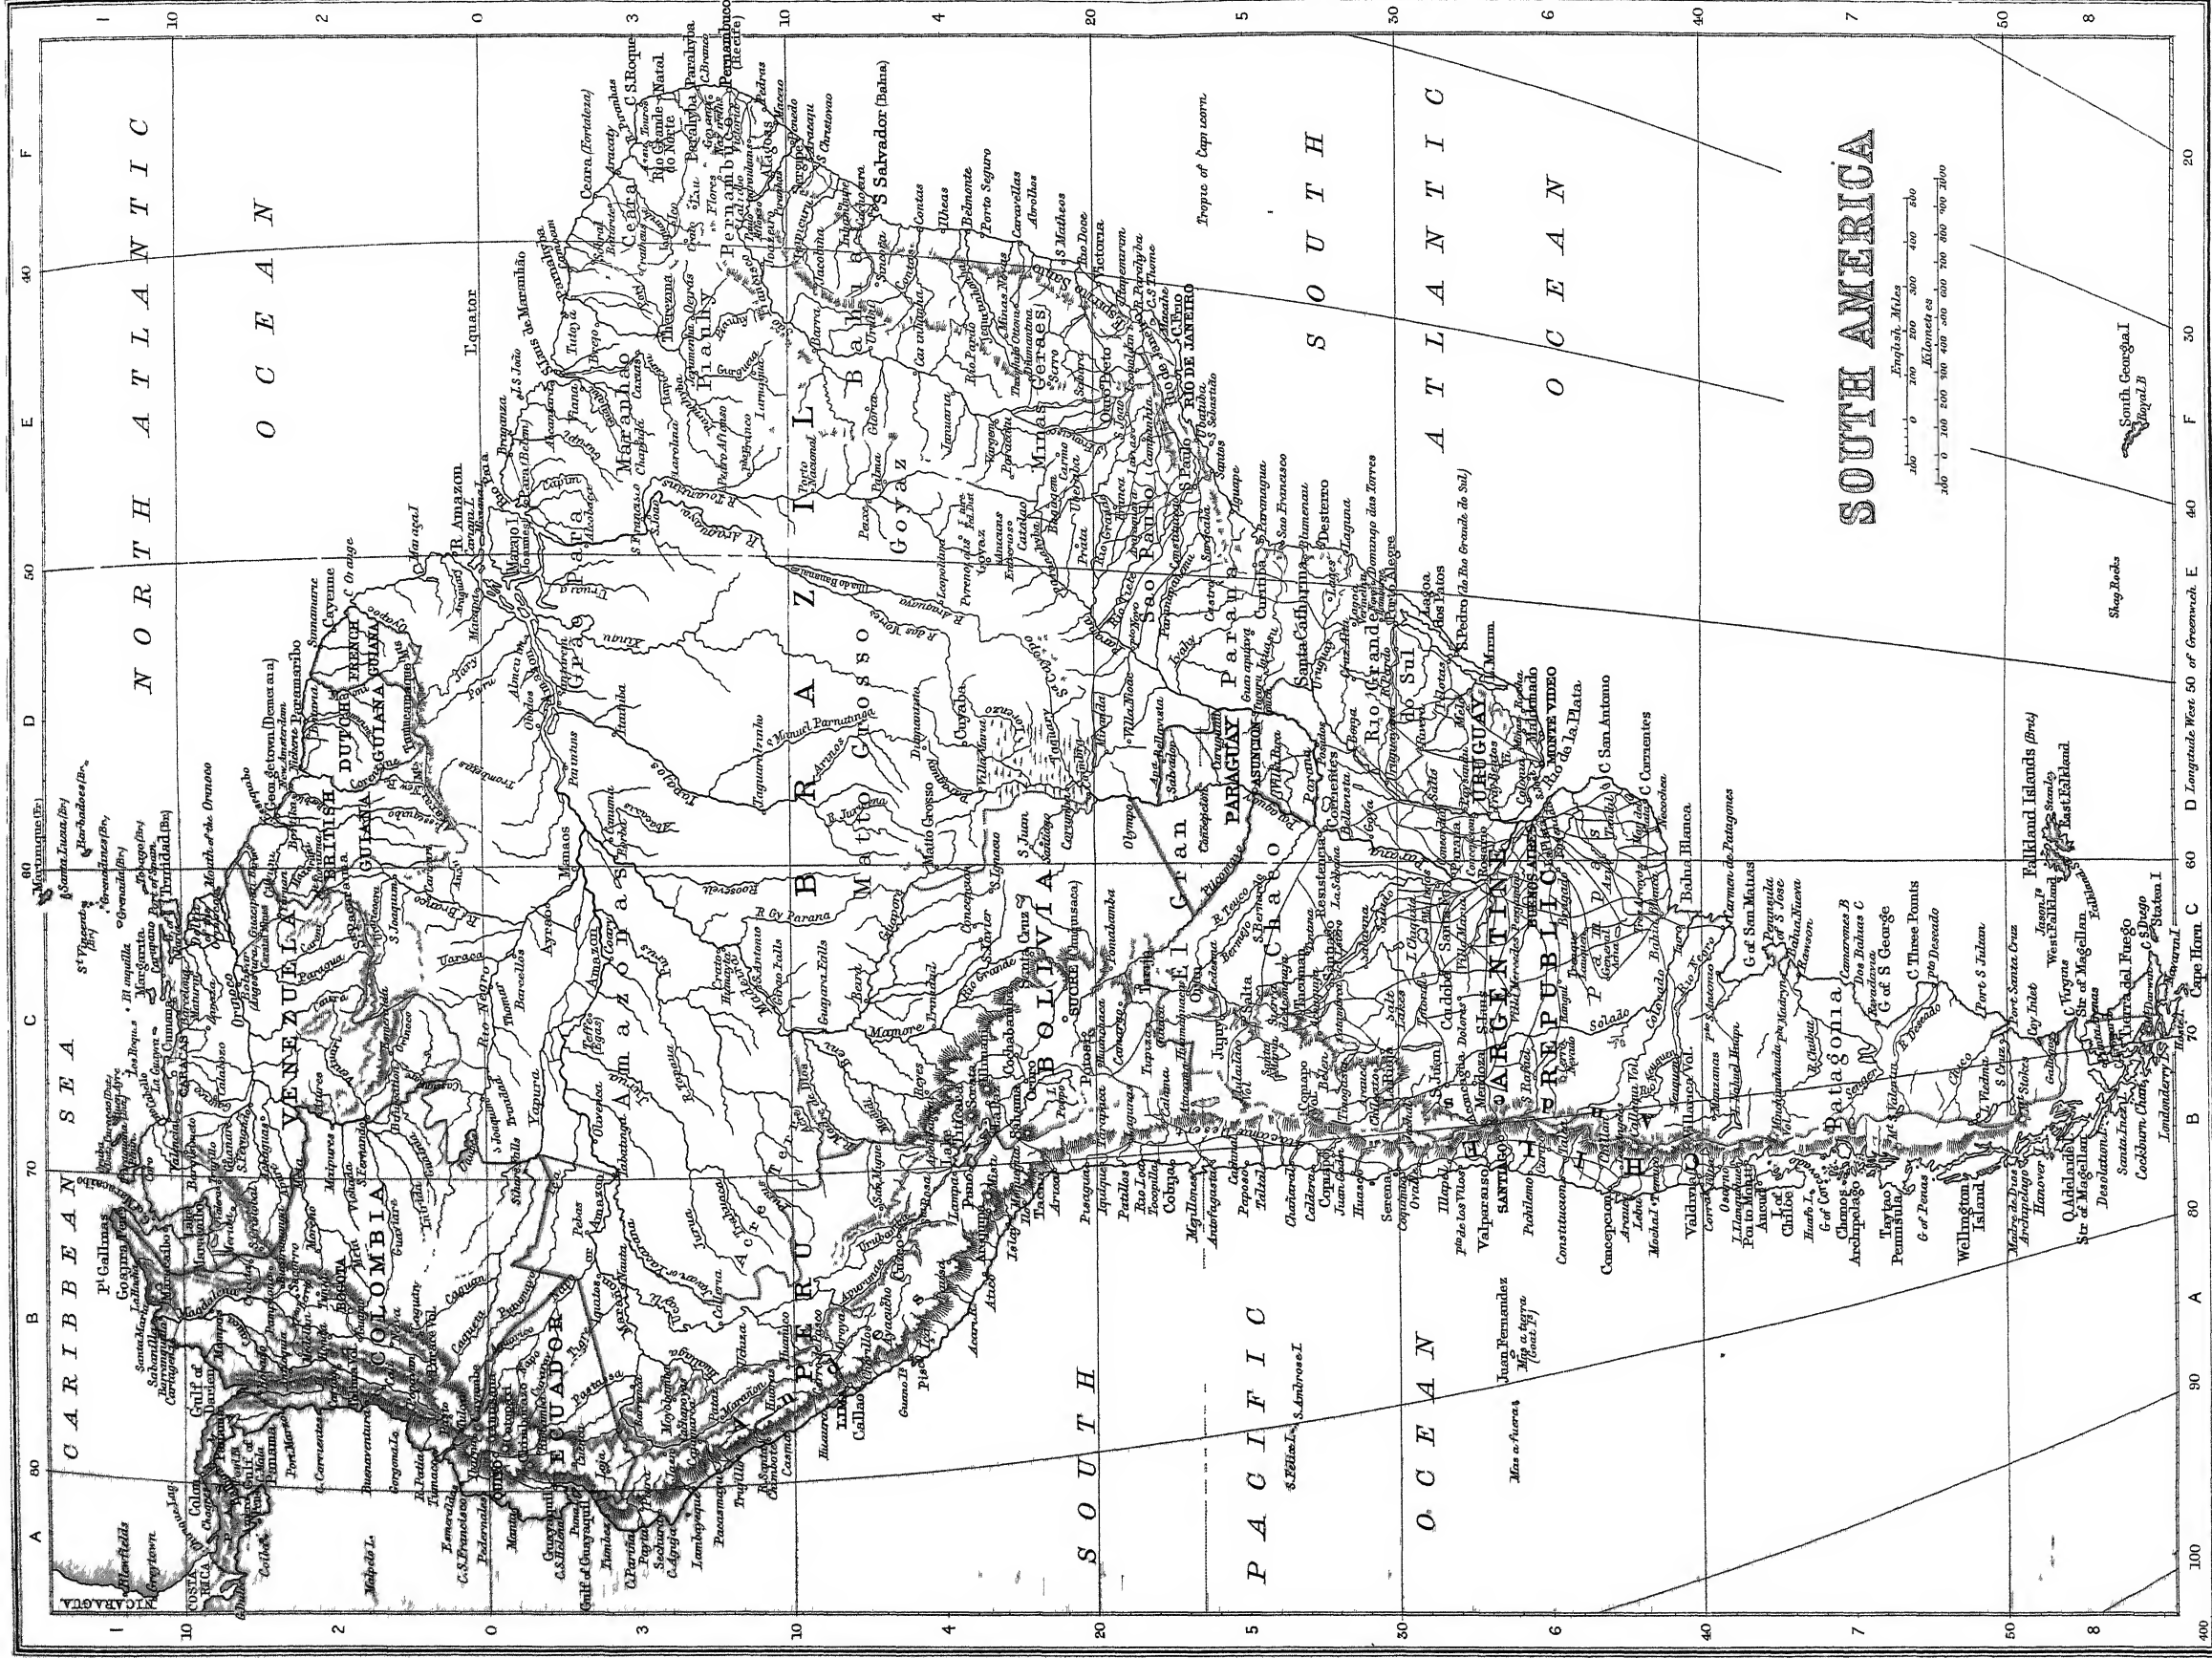

The *aboriginal population* of South America is noticed in the article AMERICAN INDIANS. The white population is largely Spanish in language and descent, except in Brazil, where Portuguese is spoken. The common people of Chile are largely of Galician (Spanish) descent; while Basque blood is said to prevail in Peru. The Brazilian whites are to a considerable extent of Azorean and Madeira stock. There are numbers of German colonists in Brazil, the La Plata countries, and Chile; and also many Italians, Basques, and other Europeans in the Argentine Republic and Uruguay. The English language is spoken in the Falklands and in Guiana; French and Dutch prevail in parts of Guiana. The negro element is strong in Brazil, in parts of Peru, and in Guiana; and there are many persons of mixed descent. It is believed that the total population of South America is about 60,000,000.

A considerable number of the islands usually reckoned as West Indian, and assigned by most geographers to North America, are really continental and South American. Such are the large British colony of Trinidad; the Venezuelan island of Margarita; and the Dutch island of Curaçoa. But the Colombian (and English-speaking) islands of Old Providence and St Andrews, though politically South American, are scarcely to be consid-

ered as South American islands. It may further be observed that the West Indian Islands, though from their latitude they are reckoned North American, are throughout marked by a flora which has few distinctly North American features; while their rather meagre indigenous animal-life is, for the most part, very clearly South American in its prominent characters.

A comparative view of the various countries of South America reveals many interesting points of likeness and contrast. The *Republic of Colombia*, in the north-west, presents an area about as large as France, Spain, and Portugal together. The coast-region and the large river-valleys have a hot climate, and afford almost every staple product of the inter-tropical zone; but a great part of the country is so elevated that its climate is a perpetual spring, and its products are largely those of temperate regions.—*Venezuela*, with vast tracts of unutilised land, presents many of the same conditions as Colombia. Cattle-breeding is here a leading pursuit, and coffee and cacao are among the principal articles of export. Venezuela is larger than France and Germany combined.—*Guiana* (British, Dutch, and French) is a region of dense forests, heavy rains, and intense heat. The seaward and well-settled parts are low and alluvial, but not really very unhealthy, except in the French colony. The area of the three colonies is about that of Sweden.—*Ecuador* consists of three distinct districts: the hot Pacific slope, rich in tropical products; a central mountain-valley region, with a delicious temperate climate; and the eastern and altogether wild and nearly unpeopled forest region east of the Andes. Ecuador has about the area of Italy. Its present conditions are not favourable to immigration.—*Peru*, with a proverbial wealth of mineral resources, and a railway system better developed than that of almost any other South American country, proved only a feeble antagonist in the Chilean war of 1879–81, which deprived the country of some of its most valued resources. For area, Peru may be compared with France, Germany, and the old Austro-Hungarian monarchy taken together.

The great republic of *Brazil* is larger than the main mass of Europe without its great peninsulas, and its natural resources are commensurate with its extent; but only a very small portion of these is developed. The mineral wealth of the country is large. Brazil, for many and obvious reasons, is a field more attractive to emigrants of the Latin races than to those of the more northern European nations; yet its southernmost provinces have a fine and temperate climate, and a very fertile soil.—The *Argentine Republic*, a country with excellent agricultural and pastoral capabilities, is progressing at a rapid rate. Its climate is in general adapted to the European constitution, and it is attracting European immigrants in large numbers. It is a large country, about six times the size of France.—*Uruguay* is a small but prosperous country, resembling the Argentine Republic in its conditions.—*Paraguay*, while somewhat larger, is less progressive.—The large republic of *Bolivia*, now everywhere cut off from the sea, is the least developed country in South America. Its surface includes several lofty and arid mountain plateaus, rich only in minerals; lower tablelands with a delightful climate, in part fertile, and in part almost a desert; and the still lower tropical and highly fertile Amazonian forest region, with almost entirely unexplored districts of great extent.—*Chile*, on the Pacific coast, is quite cut off by high mountains from easy communication with the interior. The northern part is a desert, invaded only for its mineral wealth; the extreme south has a chilly and very wet climate; but the main part of the country is extremely fertile, and has a very pleasant and

In this table, one inch equals one degree.

healthful climate. Chile is a prosperous and wealthy country. Some parts present very great attractions to the immigrant. See also CENTRAL AMERICA, and the articles on the various American countries, as Canada, United States, Mexico, and Peru; Stanford's *Compendium of Modern Geography*; the works of Hayden and Selwyn on North America, and of Bates on Central America, the West Indies, and South America; also Shaler's *Geography of North America*. For the discovery by Norsemen, see the article VINLAND; for the mythical discovery by Welshmen, see MADOC; on the discovery and early history, see various works by HARRISSE (1886-1900); and Winsor's *History of America*. In the following tables the polar regions (1,000,000 sq. m.) are not comprised; the populations are for 1910-21.

The history of America does not begin until 1492, when Christopher Columbus first sighted American land (probably Watling's Island in the Bahamas). We have abundant reason to believe, from the evidence of prehistoric archaeological studies, that men have lived in America from a very remote period. Regarding the earliest colonisation of the continent, we have no evidence at all as to the date, or place, or source of any such movement. It is certain that there were, 500 years before Columbus, Norse colonies, not only in Greenland, but much farther south. But these colonies had perished or been abandoned, and were altogether forgotten in the days of Columbus. As to whether the Chinese records which speak of visits paid by junks to a far-distant eastern land, in reality have any reference to America, opinions may differ. Most of the critics who have thought the matter worth alluding to at all have either ridiculed the idea that the Chinese ever visited America before the time of Columbus, or else have regarded such visits as having no possible value as historical events. But others have pointed out many particulars in which the Peruvian civilisation seems to have resembled that of China, and from these resemblances have inferred that the Peruvians derived their advancement from the Chinese. That the Polynesian race, on the other hand, should have colonised almost every habitable island as far as Easter Island, and never once have crossed the remaining and comparatively narrow strip of sea to Western America, seems very strange; and the fact that wampum, or money made of shells and strung together, is current in Micronesia as formerly in North America, appears to have some significance. It is, moreover, well known that under Spanish domination numbers of people of Malay race were settled in and near Acapulco; although this factor now seems to have been entirely absorbed by the older social elements. There is very little doubt (though the fact has been disputed) that America was named in honour of Amerigo Vespucci (Americus Vesputius), a Florentine, who first visited the New World in 1499. It is believed that one Hylacomylus (or Waldseemüller), a German, first named the new land America. At first it was supposed to be a part of Asia; for this reason its native people were, as they still are, called Indians. Many Spanish, Portuguese, French, and English explorers soon pushed across the sea to the newly-found world. But except the Spanish and Portuguese (who accidentally discovered Brazil in 1500, and soon colonised it), none of these founded any important American colony for more than a hundred years. In Mexico and Peru (both of them semi-civilised and rich in gold and silver), the Spanish occupation was a military conquest. Newfoundland, the oldest British colony, was not permanently settled much before 1610. The Dutch and French had each at one time large colonial interests in Brazil, of which only their Guiana plantations now remain. These, with some islands in the West Indies, are nearly all that is left to those powers of their once splendid possessions in the New World. The French in Canada were dispossessed by the English in 1762, but left their language and traditions there. Louisiana, another great and very costly French colonial experiment, was in 1803 absorbed by the United States. The English colony of Virginia dates from 1607; that of Georgia, the youngest not now under the British flag, was founded in 1733. The principal English colonies, 13 in number, became the United States of America in 1776. The Spaniards kept Florida until 1819, when it passed to the United States, which later absorbed Texas, Northern Mexico, and the Oregon

country. The English colonies north of the United States remained separate provinces until 1867, when the Dominion of Canada was formed. Newfoundland, including part of Labrador, remains a distinct colony.

British America is a name still sometimes given to what is now the Dominion of Canada, together with Newfoundland and Labrador. In a wider sense, it includes the Bermudas, the British West Indies (the Bahamas, Jamaica, Trinidad, Barbadoes, the Leeward Islands, the Windward Islands), also the Falkland Islands, and the continental colonies of British Guiana and British Honduras. The French and Dutch holdings are indicated in the table on the preceding page; and Hayti and the Dominican Republic are negro states.

Russian America was the ordinary name for Alaska (q.v.) before its purchase by the United States from Russia in 1867 for \$7,200,000.

The once vast colonies of Spain, called Spanish America, are no longer Spanish, the last of them, Cuba and Porto Rico, having been relinquished after the war of 1898. Cuba is now independent, but Porto Rico was ceded by Spain to the United States. The term Spanish America is still used for Spanish-speaking America—viz. the Central and South American republics (except Brazil), Mexico, and San Domingo. Latin America includes Spanish-speaking America, Portuguese-speaking (Brazil), and French-speaking (Hayti and French colonies).

America Cup. See YACHT.

American Aloe. See AGAVE.

American Blight, the apple-bark plant-louse, or woolly aphid, which forms a cottony film on neglected apple-trees. It is said to have been imported into Britain from America in 1787, but this is doubtful. Cleaning the trees, choking the parasites with anything oily or sticky, treatment with tobacco-water, methylated spirit, and other washes, are among the suggested remedies. The name is applied also to species attacking other trees. See APHIDES; see also *Injurious Insects* (1885), by Miss Ormerod.

American Bowls. See BOWLS, SKITTLES.

American Cedar, or RED CEDAR, is not properly a cedar at all, but the Virginian Juniper (*Juniperus virginiana*). It is used, as was the so-called Bermudas Cedar (*Juniperus bermudiana*), for making lead-pencils, cigar-boxes, &c. See JUNIPER.

American Cloth. See LEATHER-CLOTH.

American Ebony, also called Jamaica, West Indian, or Green Ebony, or Cocos Wood (*Brya Ebenus*), is a small tree of the order Leguminosæ, with scented orange-yellow flowers and flexible spiny branches. The heart-wood, which is very hard and heavy and polishes well, turns brownish-black with age.

American Elemi, a balsam-resin, known also as Gomart, Chibou, or Cachibou, obtained from the West Indian Mastic-tree, or Turpentine-tree (*Bursera gummifera*), a tree of the order Burseraceæ.

American Indians. The American Indian is a large racial group derived from the yellow-brown stem of mankind in Asia, particularly its older portions. Comprehensively he may be regarded as one of the secondary races of mankind. The terms 'Red man,' 'Red race,' &c. are misnomers, for he is yellow-brown.

Peopling of America.—As there were no higher primates on the American continent, man could not have developed there, but must have come from other parts of the globe; and as before navigation was sufficiently developed he could not have crossed the oceans from Europe or Africa, he must have

come from the only other proximate land, which is that of north-eastern Asia. The Eskimo came by the same route later.

Antiquity.—Man could not have reached America before he occupied all habitable Asia and reached its comparatively inhospitable north-eastern portions. This could possibly have been realised only in relatively recent post-glacial times. There are no indications that man has been in America more than a few thousand years. The various remains of man, both in North and South America, that have at one time or another been attributed to more ancient man were invariably on critical examination found to lack the essentials that would permit of a scientific confirmation. The earliest so far discovered cultural traces place the American man well within the Neolithic period. If he made unpolished stone implements, as he did, it was contemporaneously with more advanced forms and with pottery.

Causes and Nature of Immigration.—The conditions of north-eastern Asia favoured on one hand advance in quest of food-supply, but on the other precluded massing of people, and hence any mass immigration. The coming of the Asiatic man to America was doubtless in the main accidental, repeated, and in the nature of dribbling over rather than migration. It doubtless extended over more than one of the different practicable routes from the north of Bering Straits to the Aleutian Islands, and lasted up to very recent time, or until America was well peopled and offered resistance. Small parties of the latest Asiatics, the Japanese and Chinese, besides the Polynesians, may have reached parts of the west coast of the continent even more recently, as the Norsemen and perhaps others reached the eastern shores before Columbus; and there are suggestions that they may have brought and left certain cultural impulses, without themselves being capable of traceable survival.

Languages.—The question of the antiquity of the American Indian is generally linked with the multiplicity of his languages, it being assumed that these languages must have originated on the American continent and taken a long time for development. The native American population, though all belonging to the yellow-brown stem, shows considerable secondary physical heterogeneity, and there is every reason to believe that most of the differences were already brought to the American continent. A similar probability exists with regard to the languages. They also all belong to one great stem, though presenting various 'stocks,' some of which are almost as distant as the Semitic and Aryan; but these stocks, too, may well in the main be of extra-American origin. As more profound studies of the American languages progress, the actual number of these stocks, moreover, is steadily being reduced. Investigations under the auspices of the Canadian government indicate that the total number of linguistic stocks north of Mexico may be but six, and that possibly even some of these may eventually be shown to be related.

Cultures.—On coming into America, man brought with him his culture from Asia, and this culture, though evidently the same in fundamentals, differed in details, like the physique and language, according to time of immigration and group from which he was derived. On these foundations, and under the richer American environment, developed the native American cultures, which finally became essentially American. Much of the old, however, was retained throughout both Americas in religion, social organisation, mode of life, and general methods of behaviour.

Population : Development.—The multiplication of population under such favourable circumstances as

were offered by the new continent was doubtless rapid, as was the extension over all the better parts of the land. The latter was followed by increasing stability of geographical groups, their adaptation to the natural resources of their respective regions, and consequent cultural differentiation. In this way some of the groups remained essentially hunters or fishers, while others developed into stationary husbandmen, agriculturists, and builders of cities. It was these sedentary tribes which most rapidly advanced in culture, and which developed such remarkable culture areas and entities as those of the Ohio and Tennessee 'mound builders,' the Pueblo South-west, the Maya, Aztec, and Inca empires, and still others. The development of these cultures corresponds almost wholly to our Christian era; that of the Aztec and Peruvian empires to the last few centuries before the discovery.

Indians at Time of Discovery.—When America was definitely discovered, it was already peopled from one end of the continent to the other, including all the habitable outlying islands. The total number of inhabitants may have exceeded fifty millions. The Eskimo, as to-day, was confined to the farthest north, having never been strong enough to penetrate more southward. All the territories were already more or less definitely subdivided or claimed by the tribes. Of these there were a large number, the more advanced reaching the stage of confederations, of organised governments, and of class distinctions. Culture was advancing towards writing and in other directions, but the struggle for existence and that for power had increased far enough to involve the tribes in frequent warfare, which kept down the numbers. There was but little race consciousness or solidarity, and the white invaders had no difficulty in conquering the different groups with the help of others. It was largely the Indian who overcame the Indian.

White Man's Influence.—The white man's influence on the Indian was baneful. The two most potent agencies were, on the one hand, forcible religious disorganisation, followed by demoralisation; on the other, the introduction of diseases to which the native was not immunised, and which claimed collectively vast numbers of victims. Moreover, the white man brought with him a cultural and to some extent also intellectual superiority which was beyond the reach of the Indian. The result was the dethroning of the Indian from his sovereignty on the American continent, his weakening in every respect, and his giving way in territory and numbers, until to-day only in the Sierras and in the least accessible regions has he in small groups kept more or less his own.

The Present Status of the American Indian.—To-day the Indian is everywhere in the background. In many places he has been completely eliminated and already forgotten. His numbers have been greatly reduced, and where numerically he seems to keep up, it is by becoming more and more mixed with the white and other elements of the population. The total number of full-blood Indians does not now probably exceed in both Americas five millions. In the United States and Canada there are probably less than one hundred thousand. Only a small number of the isolated tribes still retain a semblance of independence. Whole large tribes such as the Hurons, Shawnees, Yungas, &c., have disappeared completely, or are in the process of going, through mortality and amalgamation.

The Future.—The future of the American Indian is plain: it is a partial further disappearance through disease, and amalgamation, more or less rapid according to region, with the rest of the white and other elements of the population. Before the end of the century he will have completely disappeared from the area of the United States,

though there will be several million people in whose blood he has left traces. In the wilds of Canada and in the Spanish-speaking republics the process is slower, except in Argentina, where the Indian is already practically non-existent over the vast plains from the Chaco to Tierra del Fuego.

Physical Characteristics.—Notwithstanding the presence of four or five distinct sub-types and many localised differences, the American Indian presents—or presented—throughout many features in common which permit of general characterisation.

The Indian's colour differs, according to localities and habits, from dusky yellowish or yellowish-brown to that of solid chocolate; but the fundamental colour is moderate brown, or, more correctly, yellowish-brown.

The hair, as a rule, is black (to reddish-black after exposure); it ranges about medium to slightly above in coarseness, being never fine; and it is straight, except in the old or unkempt, where there may be slight irregular waviness, and in the men who wear long hair, where the free ends may show some tendency to turn upward. The beard is scanty, and on the sides of the face generally completely absent, and it is never long. On the body there is no hair except a little in the axillæ, and on the pubis, though even there it is usually sparse.

The Indian is generally free from special characteristic odour appreciable to the white man. His heart-beat is slow. His other functions are everywhere much alike. The size of the head and of the brain-cavity, though differing considerably in individuals and also to some extent with the mean stature of the tribes, averages on the whole slightly less than that of white men and women of similar height.

His eyes, as a rule, are above medium to dark brown in colour, with decidedly bluish conjunctiva in younger children, pearly-white in older subjects, dirty-yellowish in adults; and the eye-slits show a prevailing tendency, more or less noticeable in different tribes, to a slight or moderate upward slant; that is, the external canthi are frequently more or less higher than the internal. The children show a slight to moderate epicanthus.

The nasal bridge is moderately to well arched; the nose is frequently strongly developed in the males and often convex (aquiline) in shape, but is lower, shorter, and more commonly straight or even concave in the females; it is never very high, nor so fine or slender as in whites, nor again so thick and broad as in the negro; and its relative proportions in the living as well as in the skull (barring individual and some localised exceptions) are prevalently medium or mesorhine. The malar regions are, as a rule, rather large or prominent. The suborbital fossæ are in general more shallow than in whites.

The mouth is generally fairly large to large, and the same is true of the palate. The lips average from medium to somewhat fuller than in whites, are never thin (except after loss of front-teeth and in case of alveolar absorption), and never so thick as in the negro; and the lower facial region shows in general a medium degree of prognathism, standing, like the relative proportions of the nose, nearly midway between those in the whites and those characteristic of the negroes, though frequently closer to the white. The chin is well developed, though on the average somewhat less prominent than in whites, and is not seldom square. The entire lower jaw is on the average somewhat larger than in whites. The teeth are of medium size when compared with those of primitive man in general, but frequently are perceptibly larger when contrasted with those of the cultured white American or European; the upper incisors of the Indian

present throughout, with rare individual exceptions, an especially important feature: they are on the inside, or lingually, characteristically shovel-shaped—that is, deeply and peculiarly concave, with marked marginal ridges. The ears are rather large.

The neck, as a rule, is of only moderate length, and never thin in health; the chest is somewhat deeper than in average whites; the breasts of the women are of medium size to somewhat above medium, and often more or less conical in form. In the females, the disproportion between the pelvic region and the shoulders is less marked than in whites. There is a complete absence of steatopygy, and the lumbar curve is moderate. The lower limbs are somewhat less shapely and generally less full than in whites; the calf in the majority is moderate, less than the average in either the whites or the negroes.

The hands and feet, as a rule, are of relatively moderate dimensions, and what is among the most important distinguishing features of the Indian, the relative proportion of his forearms to arms and those of the distal parts of the lower limbs to the proximal (or, in the skeleton, the radio-humeral and tibio-femoral indices) are in general, throughout the two parts of the continent, of similar average value, which differs from that of both the whites and the negroes, standing again more or less in an intermediary position.

In the Indian skeleton, from Canada to Tierra del Fuego, besides the characteristics hitherto mentioned, point after point of important resemblance or identity is met with which marks unequivocally the many distinct tribes as descendants of one and the same stem of humanity. Such features include, besides those relating to the skull, such highly distinctive traits as platybrachy in the humerus, platymery in the femur, and frequent platycnemy in the tibia; high frequency of perforation of the septum in the humerus, great rarity of the supracondylar process in any form, and other conditions. There are many tribal or local differences in these respects, but on the whole the similarity of the skeletal parts throughout the continent is such that a classification of the Indians into more than one general type becomes quite impossible.

Mentally, on the average, the Indian differs considerably from what he is commonly pictured. In general he is not quite as fine, as sharp, as capable or mentally enduring, as sentimental or emotional, or as nervous or impatient as the White; but he is far from being the stolid, cruel, indolent savage that has often been described. He loves mirth, contentment, sport of all nature, war, but also work of his own choosing; he has special endowments in oratory, art, constructive technique, and ceremonial practices, with a good capacity for organisation; he has no sharper sight, hearing, or smell than the white man, but often reaches special aptitudes in these directions through training; otherwise he is much like the ordinary White brought up under similar circumstances and with as little education. The wife is not a 'slave,' but a full mistress of her house, children, and property; and the children, among unspoiled Indians, are as carefully and lovingly brought up as any others under similar conditions. That the Indian, while perhaps not absolutely equal, is close to the White man physically as well as mentally is shown by a total absence of race repugnance between the two races. Inter-marriages are frequent; the union is generally stable, and the usually numerous children take at once their place among Whites. There is no social ostracism in their way, and their descendants may marry, if otherwise worthy, into the best of families, which is a tacit acknowledgment of the many good qualities of the Indian.

See *Handbook of American Indians* (Bull. 30, Bureau

of American Ethnology, 2 vols., Wash., 1907, and subsequent eds.), containing encyclopedic information on all phases of Indian life north of Mexico, with extensive bibliography; Bulls. 33, 52, and 66, B.A.E., dealing with Man's Antiquity on the American Continent; *Ann. Reports* and *Bulletins* of the Bur. Am. Ethnol. and of the Smithsonian Institution; A. Hrdlička, *Physical Anthropology* (Phila. 1919), containing extensive bibliography on physical anthropology of the Indians; the *American Anthropologist*; the *American Journal of Physical Anthropology*; also Clark Wissler's *The American Indian* (1917); the anthropological publications of the Peabody Museum, Cambridge, Mass., of the American Museum of Natural History, N.Y., and of the University of California.

Americanism, in Catholic theology. See HECKER; and Braun, *Amerikanismus* (1904).

Americanisms occur more frequently in speech than in writing; indeed, American authors of repute seldom employ any but pure literary English words or constructions, save in dialogue, where colloquialisms and local dialect are freely introduced.

Americanisms are mostly of three sorts. 1. New words and phrases introduced into the English language in America. Instances are *ranch*, a prairie cattle-farm; *drummer*, a commercial traveler; *skedaddle*, to run away headlong; *joyride*, a quick drive for pleasure; *make good*, to succeed; *acknowledge the corn*, to yield a point in dispute. 2. Words or phrases long current in England, to which a new meaning has attached beyond the Atlantic. Such are *clever*, in the sense of amiable or even foolish; *smart* for clever; *store* for shop; *ugly* for ill-natured; *saloon* for bar-room; and *creek* for small stream or river. 3. Words now obsolete or dialectal in England, or words used in senses no longer familiar in England, as *chore* for errand, *sick* for ill, *cunning* for pretty, and *friends* for relations. Professor Schele de Vere, in his work, *The English of the New World* (1873), maintains that the larger number of so-called Americanisms are good old English words, which have become obsolete or provincial in the mother-country. This claim, however, cannot be upheld at the present day, if we take into account the modern slang so abundant on the American side of 'The Pond.'

As regards origin, some Americanisms (words and idioms) have been borrowed from non-English-speaking inhabitants and settlers of the United States, as, for example, from the Dutch in New York (*boss, caboose, loafer, spook, stiver, stoop*), the Spaniards in California (*corral, pirogue, vamoze, cinch, ranch, cañon*), and the French in Louisiana (*bayou, cordelle, bateau, levee*). Words and phrases adopted from the German settlers in the western and middle states have been popularised by Leland's *Breitmann Ballads* in 'Pennsylvania Dutch'—*Dutchman* being an Americanism for German. From the Indians Americans borrowed, among other words, *mugwump* and *pow-wow*; *coyote* they got from the Mexicans; to negro influence we may trace such constructions as *done gone* and *this child*. But, considering the variety and mixture of races in America, such importations are relatively few in number, and the vast mass of Americanisms are of truly native origin, consisting of colloquial or slang usages applied to combinations of existing English words. Some of them are Americanisms only by virtue of the relatively greater frequency with which they are employed. Such are *I guess, I reckon, I presume, I calculate*, originally said to have been Puritan attempts to avoid the possibility of too definite a misstatement. To this class also belong *to fix* as the verb universal (*fix a meeting*=arrange; *fix myself up for dinner*=dress); *to run*, in the sense of to manage ('run a hotel,' 'run a railway,' 'Who runs this concern?')

&c.); *right* in the sense of quite or just ('tigh comfortable,' 'right here'); and *pretty* used perpetually for 'rather,' as *pretty bad*, *pretty nice*, and even sometimes *pretty ugly*. 'Is that so?' in the sense of 'Indeed!' or 'Really!' and the frequent use of 'sir' and 'ma'am' in addressing equals, are also Americanisms. Other phrases more redolent of the soil are 'not a red cent,' 'you bet your bottom dollar,' 'prospecting around,' 'toting a derringer,' and so forth. 'You bet,' as a strong affirmation, recalls the common gambling habits of the west. 'To hand in one's checks,' 'to go one's pile,' 'to hold the right bower,' belong also to the western gaming phraseology. To say that a business speculation 'pans out well' or 'stikes it rich' is obviously derived from Californian mining slang. Many phrases are evidently due to the direct influence of French ideas, and the love of the travelled American for Paris. *Baggage* for luggage, *valise* for small trunk, *depot* for railway station, *bureau* for office (and domestically for chest of drawers), *exposition* for exhibition, are cases in point. In many instances Americanisms proceed from the desire for brevity, as *pants* for trousers (pantaloons), *cars* for railway carriages, and *to wire* for to telegraph, the last now widely naturalised in England. On the other hand, where we say a lift, the Americans say an elevator; and, generally speaking, long or high-sounding words of Latin origin, which in England are mostly confined to serious writing, in America form part of the current vocabulary of everyday life. Such are *to operate* for to work, *to locate* for to place, *to eventuate* for to turn out, *to donate* for to give, *to opine* for to think, *to approbate* and *capitivate* for to approve and capture; *tardy* in the sense of late for school; *caption*, a heading or title; *institution*, *lyceum*, or *academy* for school or college; *recitation* for lesson, *proclivities* for tastes, *eminence* for hill, *residence* for house, *elegant* for pretty, *vacation* for holidays, and *prominent citizens* for well-known men. In like manner *to ambition* is used for to aim at, *to suspicion* for to suspect.

Among Americanisms most familiar or most noticeable to Englishmen may be mentioned: *any* for at all; *aside from* for apart from; *back of* for behind; *bug* for any insect—e.g. *lightning bugs*, fireflies; *to boost*, push or boom; *block*, a square of buildings; *candy*, sweetmeats; *conductor*, guard of a train—introduced about 1880 into England, according to Mr R. H. Thornton (who himself falls into an Americanism) by the 'Midland Railroad'; *corn* for Indian corn; *cracker*, biscuit; *cute*, shrewd; *fall*, autumn; *to favor*, to look like; a *fish story*, cock-and-bull story; *fool*, foolish; a *half after ten*, half-past ten; *lot*, piece of land; *most* for almost; *none* or *nohow*, not at all; *plenty*, plentiful; *side-walk*, pavement; *slick*, smoothly, quickly; *some*, somewhat, remarkable.

Many Americanisms may be classed as (a) words indicating things distinctively American; (b) nicknames for persons and places; or (c) expressions invented or adopted to describe phenomena of American life, political, financial, social, &c. Examples of (a) are: *backwoods*, *buckeye* (American horse-chestnut), *cocktail*, *cow-catcher*, *doughnuts*, *hangbird*, *homing*, *huckleberry*, *locust* (pseudo-Acacia), *opossum*, *peanut*, *persimmon*, *popcorn*, *ragtime*. (b) *Old Hickory*, Andrew Jackson; *Greaser*, Mexican; *Keystone State*, Pennsylvania; *Monumental City*, Baltimore; *Bluenose*, a native of Nova Scotia or New Brunswick. (c) *To bolt* a nomination or to rat, to desert one's party; on the stump, electioneering, gerrymandering, lobbying, log-rolling; *cactus*, *graft*, *machine*, *platform*, *plank*, *ticket* in political parlance; *bogus*, *bucket-shop*, *slump*, *wildcat* schemes; *dago*, *crook*, *dude*, *hobo*, *woodlump*, and many other derogatory terms.

Among obsolete English forms current in America may be quoted *gotten* (got), *dove* (dived), *her'n* and *his'n* (heirs and his), *happen* (to be) *in* (a place). The tendency to take our slang in particular from American sources is largely on the increase, and has been strengthened partly by the diffusion of works like Mark Twain's and Frank Stockton's, partly by the increased intercourse between the two countries, and partly by the influence of the cosmopolitan Americans who throng the Continent.

In the New England states the Americanisms in use are chiefly those of the older crop—that is to say, the English words now obsolete or provincial, and the words evolved on the soil for new objects or recent inventions. In the south, among the white population, almost pure English is generally spoken. But in the middle states, and still more in the west, slang is rife, and startling Americanisms form the mass of the colloquial language. All over America, including Canada, the spoken tongue tends to be far less correct than the written. People who write *is not*, say *ain't*; people who write *almost always*, say *most allus*; people who write *very ordinary*, say *pretty or'nerly*.

Americanisms in spelling are chiefly due to the influence of Noah Webster's dictionary, which in many cases adopts an orthography not sanctioned by British authorities, as practiced, offenses, labor, theater, traveler, traveled, mold, fulfillment.

H. Thornton, *An American Glossary* (1912); Mencken, *The American Language* (1922).

American Organ. See HARMONIUM.

Amerigo Vespucci. See VESPUCCI.

Amerongen, a Netherlands village, 21 m. SE. of Utrecht. Count Bentinck's castle became the retreat of the deposed Kaiser William II.

Amersfoort, an ancient town of the Netherlands, 14 miles NE. of Utrecht by rail. It has a large trade in grain; tobacco is grown in the district; brandy, cotton, linen, and woollen goods, leather, soap, and beer, are manufactured. Here was Oldenbarneveld born. Pop. 31,000.

Amesbury, a village of Wilts, 7½ m. N. of Salisbury, the traditional place of Queen Guinevere's retirement and penance—an example long fashionable for great ladies. The name (O.E. *Ambresbyrig*) perhaps connects it with Ambrosius Aurelianus, leader of the Britons against the English invaders. Stonehenge (q.v.) and a great British camp are close by. See COURSING.

Amethyst, a variety of Quartz (q.v.), differing from common quartz and rock-crystal chiefly in its beautiful violet-blue or purplish-violet colour—well known as *amethystine*—which is owing to the presence of a little peroxide of iron or of manganese. It is one of the most esteemed varieties of quartz, and is much employed for seals, rings, &c., although, being comparatively abundant, it is much inferior in price to the true gems. An amethystine tinge is frequently to be observed in specimens of quartz, which yet are not perfect amethyst. The tinge is often very faint, and is frequently confined to the summits or edges of the crystals. The finest specimens of amethyst are brought from India, Ceylon, and Brazil. It is, however, a common mineral in Europe, and occurs in many parts of Scotland. It frequently occurs lining the interior of balls or geodes of agate, and in veins and cavities in basalt, diabase, and other igneous rocks. The ancients imagined it to possess the property of preventing intoxication, and persons much addicted to drinking therefore wore it on their necks. The name is derived from a Greek word which signifies *unin-*

toxicated.—Not to be confounded with this mineral is that sometimes called the *oriental amethyst*, which is a purple variety of Corundum (q.v.), and is a very valuable gem. False amethysts made of glass or paste are common, and in general coarse; but a very perfect imitation is sometimes made.

Amhara ('the high lands'), the largest of the three older divisions of Abyssinia, extending from the Tacazzé to the Blue Nile, and embracing the beautiful Lake Tzana (see ABYSSINIA). Capital, Gondar (q.v.). The *Amharic language* is spoken, with local variations, throughout Abyssinia, and has, except in Tigé, entirely superseded the Ethiopic, or Geez, to which it is related (see ETHIOPIA, SEMITIC LANGUAGES). Like the latter, it is of Semitic origin, but has been largely corrupted with non-Semitic African admixtures.

Amherst, a seaport of Tenasseim, Burma, at the mouth of the Salwin, 30 miles S. of Maulmain. Founded in 1826 as the capital of the province, it was superseded next year by Maulmain, and is now of no importance.

Amherst, a seaport of Nova Scotia, on Cumberland Basin, an inlet of the Bay of Fundy; pop. 10,000.

Amherst, a village in Massachusetts, 20 miles N. of Springfield, seat of Amherst College (founded 1821) and a state agricultural college; pop. 5000.

Amherst, JEFFREY, Baron Amherst (1717-97), born at Riverhead, Kent, as a boy was a page to the Duke of Dorset, who in 1731 procured him an ensigncy in the Guards. In 1758 Pitt gave him the command of the expedition against the French in Canada; and Canada was ours by the autumn of 1760, thanks to his prudence and to Wolfe's enthusiasm. This was the great achievement of his life, though in 1772 he became officiating commander-in-chief, and in 1796 a field-marshal, having been raised to the peerage in 1776. He died at Montreal, his Kentish seat. See *Life* by L. S. Mayo (1916).—His nephew, WILLIAM PITT AMHERST, Earl Amherst of Amakan, was born in 1773, and succeeded as second baron in 1797. His embassy to China (1816) failed through his manly refusal to 'kowtow' to the emperor; but, in spite of that failure, he received in 1823 the governor-generalship of India. For the successful first Burmese war, and for the capture of Bhutpore, he was rewarded with an earldom in 1826. Two years later he returned to England, and, after nearly thirty years of comparative retirement, died at Knole Park, Kent, 13th March 1857.

Amherstburg, a town of Ontario, Canada, at the head of Lake Erie, 4 miles S. of Detroit. It has a large timber trade. Pop. 2800.

Amianthus. See ASBESTOS, AMPHIBOLE.

Amice, a cape or hood formerly worn by priests and pilgrims. Also, a strip of fine linen, with a piece of embroidered cloth sewn upon it, worn upon the shoulders by priests of the Roman Catholic Church in the service of the Mass. The bands sometimes worn by Protestant clergymen are a relic of this garment.

Amides was the name originally applied to a group of organic compounds, derived from ammonia, NH_3 , or NHHH , by the exchange of one or more atoms of hydrogen for a corresponding number of atoms of a metal or a compound radical. At present the term *amide* is restricted to the case in which one or more atoms of hydrogen are replaced by an *acid radical*, and the amides are called primary, secondary, or tertiary, according as one, two, or all three of the atoms of hydrogen are replaced. The primary amides may be obtained in various ways, of which we shall mention two: (1) If we heat an ammoniacal salt, one molecule of water is given off, and an amide is obtained:

(2) By treating an acetyl chloride with ammonia gas, the acetyl group is substituted for one atom of the hydrogen of ammonia:

Amiel, HENRI FRÉDÉRIC (1821-81), was born at Geneva. After travelling in Italy, he studied at Berlin (1844-48), returned to Geneva saturated with German science and philosophy, and in 1849 became professor of *Æsthetics* and French Literature; which chair, four years later, he exchanged for that of Moral Philosophy. His wide culture, critical power, and profound but melancholy speculation were revealed to the outside world by a selection published after his death from his *Journal Intime* (2 vols. 1882-84; Eng. trans. 1885). He also wrote poetry. See Berthe Vadier's *Henri Amiel* (1885), and G. Frommel's *Études littéraires et morales* (1909).

Amiens (ancient *Samarobriva*), an old French city, the capital once of Picardy, and now of the department of Somme, on the many-channelled, navigable Somme, 81 miles N. of Paris by rail. Its fortifications have been turned into boulevards, but it retains its old citadel. The cathedral of

Amiens Cathedral.

Notre Dame, begun in 1220, is 452 feet long, and has a spire (1529) 426 feet high; but its special feature is the loftiness of the nave, 141 feet. It survived the great European war intact. In *The Bible of Amiens*, Ruskin says this church well deserves the name given it by Viollet-le-Duc, 'the Parthenon of Gothic architecture,' and that its style is 'Gothic pure, authoritative, and unaccusable.' Other noteworthy buildings are the Hôtel-de-Ville (1600-1760), in which the Peace of Amiens was signed; the large museum (1864) in Renaissance style; and the public library (1791). Amiens

has considerable manufactures of velvet, silk, woolen, and cotton goods, ribbons, and carpets. Peter the Hermit and Ducange were natives, and have statues. The 'Mise of Amiens' was the award pronounced by Louis IX. of France, in 1264, on the controversy between Henry III. of England and his people as to the 'Provisions of Oxford.' The 'Peace of Amiens' (March 27, 1802) was a treaty intended to settle the disputed points between England, France, Spain, and Holland. By it England retained possession of Ceylon and Trinidad, and an open port at the Cape of Good Hope; the republic of the Ionian Islands was recognised; Malta was restored to the Knights of St John; Spain and Holland regained their colonies, with the exception of Trinidad and Ceylon; the French were to quit Rome and Naples; and Turkey was restored to its integrity. In 1870 Manteuffel signally defeated the French near Amiens, and three days later the citadel surrendered. The Germans took Amiens in September 1914. Pop. 93,000.

Amines, a class of organic compounds derived from ammonia (NH_3) by replacing the hydrogen atoms by univalent groups—alkyls (or alcohol radicals). They are classified as primary, secondary, or tertiary, according as one, two, or three atoms are replaced. The outstanding univalent groups may also be those of the atomatic series—e.g. phenylamine, $\text{C}_6\text{H}_5\text{NH}_2$, better known as aniline. The alkylamines (amines of the fatty series) are very similar to ammonia in their properties. The lower members are gases, combustible (being thus distinguished from ammonia), and readily soluble in water. The higher members are liquids, soluble in water; whilst the highest are solids, sparingly soluble in water. The amines, like ammonia, combine with acids to form salts, which differ from ammoniacal salts by being soluble in alcohol. Methylamine (CH_3NH_2), the simplest primary amine, is found in bone-oil, in the distillate from wood, and is produced in the decomposition of various natural alkaloids—e.g. morphine, creatine. Trimethylamine ($(\text{CH}_3)_3\text{N}$ —a tertiary amine—has a penetrating fishy odour, is present in herring-bone, and is a by-product in beet-sugar manufacture.

Amirante Islands, a group of eleven low wooded islands SW. of the Seychelles; area, 32 sq. m.; pop. 100 French-speaking half-breeds. They fell to Great Britain in 1814, and in 1888 were attached to the Seychelles administration.

Amiwell, a small seaport and watering-place, since 1901 an urban district, on the north coast of Anglesey, 2½ miles NNW. of the Menai Bridge by rail. The closing of the copper-mines on Parys Mountain (2 miles to S.) greatly reduced the prosperity and population of the district. These mines were probably known to the Romans. A rich vein of ore was struck in 1768. Pop. 2700.

Amman. See KERAK.

Ammanati, BARTOLOMEO, architect and sculptor, was born at Florence in 1511, and died in 1592. He was a pupil of Bandinelli and Sansovino. Pope Julius III. employed him in the decoration of the Capitol, and Cosmo de' Medici appointed him his architect. His works have all a certain grandeur of character, but are marred by mannerisms.

Ammergau. See OBER-AMMERGAU, MYSTERIES AND MIRACLE PLAYS.

Ammianus Marcellinus, a Roman historian, born of Greek parents at Antioch in Syria, about 330. After serving in several campaigns in Gaul, Germany, and the East, he settled at Rome, devoted himself to literature, and was alive as late as 390. He wrote in Latin a history of the Roman empire from 96 to 378 A.D., in 31 books, of which only 18 books are extant, comprising the years 353

to 378. This part of the work, however, is the most valuable, being a highly important contemporary source for the history of the Emperor Julian. The work may be regarded as a continuation of Tacitus, and though the portions remaining have many faults of style, they are valuable on account of the author's careful descriptions of countries and events from personal observation.

Ammon. See KERAK.

Ammon, a god of the ancient Egyptians, worshipped especially in Thebes (*No-Ammon*), and early represented as a ram with downward branching horns, the symbols of power; as a man with a ram's head; and as a complete man with two high feathers on his head, bearded, sitting on a throne, and holding in his right hand the sceptre of the gods, in his left the handled cross, the symbol of divine life. Ammon, his wife Mut ('the mother'), and his son Chensu, form the divine triad of Thebes: their worship was at its greatest height under the 18th to the 20th dynasty. The name signifies the hidden, unrevealed deity; and in Egyptian mythology he held the highest place. His undefined character may serve to explain how other deities were identified with Ammon. After the 18th dynasty we find in hieroglyphics the name *Amun-Ra* frequently inscribed, indicating a blending of Ammon with the sun-god Ra. Similarly, the representation of Ammon with a ram's head shows the blending of him with Kneph. From about the time of the 21st dynasty, he came to be considered the god of oracles, and as such was worshipped in Ethiopia and in the Libyan Desert. Twelve days' journey west of Memphis, in the desert was a green oasis fringed with a belt of palm trees, on which rose the temple of Ammon. Hither came pilgrims laden with costly presents; among them Alexander the Great and Cato of Utica. Alexander was hailed as the actual son of the god by the priests, quick to anticipate the wishes of the hero. The Persian conqueror Cambyses sent against the temple an expedition, which perished miserably in the sands. The worship of Ammon spread at an early period to Greece, and afterwards to Rome, where he was identified with Zeus and Jupiter.

Ammon, CHRISTOPH FRIEDRICH VON, a German theologian, born in 1766, was professor of theology at Erlangen and Göttingen, and court-preacher at Dresden, where he died in 1850. He wrote handbooks of biblical theology, church history, and Christian ethics. He may be said to have stood midway between supernaturalism and rationalism.

Ammonia, HARTSHORN, or the VOLATILE ALKALI, was one of the few substances known to the chemistry of the ancients; being referred to by Pliny under the name of *vehement odour*, which he evolved by mixing lime with nitrum (probably sal ammoniac). It derives its name ammonia from its being obtained from sal ammoniac, which was first procured by heating camels' dung in Libya, near the temple of Jupiter Ammon. The atmosphere contains a minute quantity of ammonia, amounting to 210 to 247 parts in 10,000,000,000 parts of air, which is equal to 1 volume of ammonia in 28,000,000 of air. It is likewise present in rain-water in variable proportion. The supply of ammonia to the atmosphere is due to its evolution during the putrefaction of animal and vegetable substances, during the vinous fermentation, and the combustion of coal. It is likewise present in respired air, and is therefore a product of the daily wear and tear of the animal system. The commercial source of ammonia at the present time is the destructive distillation of coal, as in gas-making, when it is got as a by-product. The mixed gases from the furnaces pass through water in which the tarry matter is collected, and

a large proportion of ammonia dissolves. This solution is known as 'ammoniacal liquor.' This is heated with slaked lime, and the gas evolved is caught in dilute acid (either hydrochloric or sulphuric) and forms either ammonium chloride or sulphate. The ammonium chloride is known commercially as 'sal-ammoniac,' and is purified by sublimation. Pure ammonia is manufactured from this impure chloride of ammonium by mixing it with its own weight of slaked lime in a retort, and applying a gentle heat, when the ammonia as a gas passes over, and is received in a vessel containing water. The solubility of ammonia in water is very great, 1 volume of water at 32° F. (0° C.) dissolving 1050 volumes of ammoniacal gas.

The *liquor ammoniac* of the chemists, or *hartshorn* of the shops, contains about 32 per cent. by weight of the gas, and it is lighter than water, its density being .891. The solution of ammonia is transparent, colourless, and strongly alkaline. In taste it is acrid caustic, and in odour very pungent. Applied to the skin in a concentrated form, it blisters. As generally obtained, it is in combination with water, and may be represented by the formula NH_4HO . Dry ammonia can be procured by passing the vapour of ammonia, as ordinarily obtained, over fused chloride of calcium, when the water is abstracted, and true gaseous ammonia is left, having the composition of one atom of nitrogen and three of hydrogen, NH_3 . Gaseous ammonia can be liquefied under pressure and cold, and then yields a colourless, clear, mobile liquid. Liquid ammonia was one of the first substances used for refrigerating purposes. The ammonia gas is liquefied by pressure, being kept cool by a water-jacket. The liquid then passes into pipes surrounded with brine, and is allowed to evaporate. The brine cooled thereby is circulated through the refrigerating chambers, and returns to be cooled again by the evaporation of the liquid ammonia as before. Ammonia combines with acids to form a class of salts which are of considerable importance. Thus, the crystallised sulphate of ammonia, $(\text{NH}_4)_2\text{SO}_4$, is very extensively used as a top-dressing by farmers, and is also mixed with manures where an increase of ammoniacal matter is desirable. The chloride of ammonium is also employed in agriculture; likewise largely by the Russian peasantry, in place of common salt, as a condiment for food. See MINDERERUS SPIRIT.

In medicine, the gaseous ammonia has been rarely used. The solution of ammonia is employed as a means of rousing the respiratory and vascular systems; and of the speedy alleviation of spasm. It is also used as a local irritant and antacid. It is serviceable in dyspeptic complaints with preternatural acidity of stomach and flatulence; to produce local irritation or destruction of certain parts, and to render comparatively harmless the bites of poisonous animals, such as serpents and insects.

Ammonium is the term applied to the group of atoms represented by the formula NH_4 . As this group enters into the composition of many salts, exactly in the same way that potassium, sodium, and other metals do, the term *hypothetical metal* has been applied to it, although no one has ever succeeded in isolating it. Ammonium may be prepared by acting on an amalgam of sodium and mercury with a solution of chloride of ammonium. A portion of mercury is slightly heated in a porcelain vessel, and pieces of sodium introduced, when the sodium and mercury combine, and form an amalgam of sodium and mercury, which is a semi-solid substance, and scarcely occupies more space than the bulk of the mercury employed. If this be introduced into a vessel containing a strong or saturated solution of chloride of ammonium, NH_4Cl , the chlorine combines with the sodium, Na, of the amalgam, forming chloride of sodium,

NaCl, and the ammonium unites with the mercury, forming the amalgam of ammonium and mercury. As the change referred to proceeds, the amalgam increases in size many times, and forms a spongy mass of the consistence of butter, which rises through the saline solution and floats on the surface. The amalgam of ammonium and mercury very readily decomposes, and hence the difficulty of determining its exact composition.

Ammoniacum, or AMMO'NIAC, a gum resin, used in medicine on account of its stimulant and expectorant qualities, is obtained from *Dorema Ammoniacum*, a plant of the natural order Umbelliferae, a native of Persia—a perennial about seven feet high, with large doubly pinnate leaves. The leaves are about two feet long. The whole plant is abundantly pervaded by a milky juice, which oozes out upon the slightest puncture, and which hardens, and becomes ammoniacum. The ammoniacum exudes from punctures made by a beetle, which appears in great numbers at the time when the plant has attained perfection. It occurs in commerce either in tears, or in masses formed of them, but mixed with impurities. It is whitish, becoming yellow by exposure to the atmosphere, is softened by the heat of the hand, and has a peculiar heavy unpleasant smell, and a nauseous taste, at first mucilaginous and bitter, afterwards acrid. It is not fusible, but burns with white crepitating flame, little smoke, and strong smell.

Ammoniaphone, an apparatus designed by Moffat (1880) to improve the human voice by the inhaling of air saturated with peroxide of hydrogen and free ammonia. For a time the invention found favour with singers and speakers.

Ammonite is the name of one of the 'high explosives,' which comprise also Ardeer powder, bellite, carbonite, roburite, and securite. See BLASTING, DYNAMITE, EXPLOSIVES, GUN-COTTON, NITRO-GLYCERINE, PICRIC ACID.

Ammonites, a Semitic race of people, living on the edge of the Syrian Desert; according to Gen. xix. 38, the descendants of Lot, and closely akin to the Moabites. They inhabited the country lying to the north of Moab, between the rivers Arnon and Jabbok. Their chief city was Rabbath-Ammon. The Israelites were often at war with them. Jephthah defeated them with great slaughter, and they were also overcome by Saul, David, Uzziah, and Jotham; but after the fall of the kingdom of Israel (721 B.C.), they spread themselves in the districts east of the Jordan. They sometimes secured the alliance of Syria, of Nebuchadnezzar, and of Arabian tribes, in their wars with the Jews. After the captivity, they endeavoured to hinder the restoration of the Jewish state, but were finally conquered by Judas Maccabæus. Justin Martyr affirms that in his time the Ammonites were still numerous. From the name of their princes, it is evident that their language was closely akin to Hebrew. Their chief deity was Moloch, and under that head their religion is discussed.

Ammonites, a group of fossil shells, nearly allied to the recent genus *Nautilus*, being, like it, chambered and spiral. The molluscous inhabitant appears to have lodged in the last and largest chamber of the shell, the spaces left behind as it increased in size being successively converted into air-chambers, and all connected by a tube (*siphuncle*), so that the animal could at pleasure ascend or descend in the sea; whilst the transverse plates dividing the chambers gave strength to the whole structure without great increase of weight. In the *Nautilus* these dividing plates (*septa*) are simple and curved, and their edges (*sutures*) plain; but in the Ammonites the *septa* are often very

complex, and the sutures zigzagged, foliated, or irregularly lobed. Ammonites have long been popularly called *Cornua Ammonis*, from a fancied resemblance to the horns on the sculptured heads of Jupiter Ammon. In former times they were ignorantly mistaken for petrified snakes; and impositions have been practised on collectors by adding to specimens nicely carved snakes' heads; whilst the general absence of heads was popularly accounted for by a legend of a saint decapitating the snakes, and turning them into stone. The family to which the Ammonites belong (Ammonoidea) ranged from Palæozoic to Mesozoic times, and embraced a number of different forms. In some the shell is straight (Bactrites, Baculites); others are bent on themselves (Ptychoceras); some are curved (Toxoceras); then we have an elegant

Ammonites:

1, *Ammonites obtusus*; 2, section of *Ammonites obtusus*, showing the interior chambers and siphuncle; 3, *Ammonites nodosus*.

spiral form (Turrilites); besides discoidal and semi-discoidal forms (Crioceras, Ancyloceras), and involute types such as Ammonites (of which there are many types), Goniatites, Ceratites, &c. The most prominent Palæozoic representatives of the family are Goniatites and Clymenia. The Ammonites proper are Mesozoic forms, and are characteristic of the Jurassic and Cretaceous systems. In the former system especially, particular species distinguish particular zones, which renders the group of great interest and importance to the geologist; for some of these zones are persistent over wide regions. The number of species of true Ammonites is very great, several hundreds being known. They differ much in size, some being quite minute, while others are as large as cart-wheels.

Ammoni'um, the site of the famous temple of Ammon in the Libyan Desert, the modern oasis of Siwah. See AMMON, OASES; see also AMMONIA.

Ammoni'us, surnamed SACCAS ('sack-carrier'), a Greek philosopher, founder of the Neo-Platonic School, is said to have been in his earlier days a porter in Alexandria, whence his surname. His parents were Christian, but he himself is said by Plotinus to have abandoned his early religion; although both Eusebius and St Jerome deny his apostasy. He opened a school of philosophy in Alexandria, and sought to harmonise, through a comprehensive eclecticism, the philosophies of Aristotle and Plato. He seems also to have added elements of oriental speculation; but it is doubtful how far Neo-Platonism represents his own position. His most distinguished pupils were Origen and Plotinus. Ammonius Saccas died at Alexandria, 243 A.D., at the age of more than eighty. He left no writings behind him.

AMMONIUS was also the name of a Peripatetic philosopher of the 1st century, the instructor of Plutarch; of a Christian philosopher of the 3d century, who wrote a 'Harmony of the Gospels'; of a philosopher of the 5th century, a disciple of Proclus, who left important commentaries on Aristotle; and of an Alexandrian grammarian of the 4th century.

Ammophila. See REED.

Ammunition is a term once used for all military stores; now only for materials employed in charging firearms. Ammunition wagons are specially constructed for carrying different kinds of ammunition. See the articles BULLET, CANNON, FIREARMS, FUSE, GUN, GUNNER, GUNPOWDER, RIFLES, SHOT, SHELL, TORPEDO, and the like.

Amne'sia is loss of memory. See MEMORY.

Amnesty (from Greek words for 'not remembered') signifies an act of pardon or oblivion, and the effect of it is, that the crimes and offences against the state, specified in the act, are so obliterated that they can never again be charged against the guilty parties. While pardon exempts individuals from the punishment the law inflicts for their offence, an amnesty is generally granted to a whole class of offenders. The word is also applied to clauses in a treaty of peace which grant immunity from civil or criminal processes to which persons might be otherwise exposed in consequence of their conduct in the war. The amnesty may be either absolute, or qualified with exceptions. Bonaparte, on his return from Elba in 1815, declared an amnesty, from the benefits of which he excepted thirteen persons whom he named. Upon the restoration of Charles II., the persons actually concerned in his father's execution were,

as a class, excluded from the amnesty granted. It is of importance that exceptions should be specific, and not, as in the Bourbon Amnesty of 1816, of a general kind, so as to leave doubt and uncertainty in the public mind. The amnesty to all who were guilty of treason against the United States, or adhered to their enemies during the Civil War, included domiciled aliens. But the proclamation (1868) did not entitle one whose property had been sold under the Confiscation Act of 1862 to reclaim the proceeds after they had been paid into the treasury of the United States. The French pardoned 2245 Communards by decree in 1879, and granted a general amnesty for political offences in 1880.

Amnias, or AMNEUS, a river of Pontus, on which the generals of Mithradates (q.v.) defeated the Bithynians, 88 B.C.

Amnion is a foetal membrane which immediately invests the embryo, appearing very early in the development of the latter, and adhering closely to it. Double folds grow round the embryo, arching over it on all sides, and uniting in a central point. The origin of the anterior and posterior folds is indicated in the diagram (A.F.) The inner layer of this double fold becomes separate from the outer and forms the amnion, while the outer portion forms the chorion, which when vascularised by the vessels of the embryo takes its place as the foetal part of the placenta. In fishes and amphibians it does not exist, but is found in reptiles, birds, and mammals. As gestation proceeds, this membrane secretes from its inner surface a fluid which distends the amnion, within which the foetus floats suspended by its umbilical cord. That this fluid, the *liquor amnii*, is of foetal origin, is shown by its occurrence in

A.F., amnion-fold; E., embryo; G.C., gut-cavity; Y.S., yolk-sac. (After Weidersheim.)

is of foetal origin, is shown by its occurrence in

birds. It consists of water, containing epithelium, hairs, and $\frac{1}{2}$ to 2 per cent. of fixed solids. In mammals, the foetal urine is added to it during the second half of pregnancy. Its specific gravity varies from 1007 to 1011. The fluid preserves the foetus from injury and pressure, permits of the free movement of its limbs, and prevents them from growing together. When gestation is completed, and labour commences, the amniotic fluid is the chief mechanical agent in dilating the os uteri, and so opening the way for the foetus. See EMBRYO; and for many curious superstitions connected with the subject, see CAUL.

Amoeba (Gr., 'change'), a name given to a number of the simplest animals or Protozoa (q.v.), which consist of unit masses of living matter (see CELL, and PROTOPLASM). They are found in fresh water or in mud, and occasionally in damp earth (*A. terricola*). One of the commonest was first described in 1755 by an early microscopist, Rösé von Rosenhof, and the name he gave it—*Proteus animalcule*—still survives in popular language. They are all minute, but some are distinctly visible with the unaided eye. The naked mass of living matter or protoplasm flows out in all directions in blunt processes (*pseudopodia* = 'false feet'), and the endlessly varying form has earned for these simple animals their technical and popular names of

Amoeba:

- 1, amoeba with blunt processes, nucleus, nc; contractile vacuoles, vc; food vacuoles and granules. 2, two daughter amoebae. 3, amoeba in process of dividing. 4, encysted phase, with inclosed diatoms, &c. (After Butschli and G. B. Howes)

amoeba and *Proteus animalcule*. Many unit masses or cells of higher animals—e.g. the white corpuscles of the blood—exhibit the same ceaseless change of form, which is generally described as *amoeboid*. The outer layer of the protoplasm is usually firmer than the interior, and in reference to this physical difference the terms *ectosarc* and *endosarc* are often used. The central portion contains the more refractive body or nucleus, which is so characteristic of all cells, and which evidently plays an important part in the life of the animal. More than one nucleus is often present. The amoeba flows along the surface of stone or plant by the slow protrusion of the ever-changing processes. In this way, too, it flows over, and gets outside particles of food, such as diatoms, which are engulfed in the protoplasm, and form with the little bubble of water surrounding them what are known as *food-vacuoles*. The available material, which may be either vegetable or animal, is slowly digested, and the refuse expelled. As the result of internal changes, granules and globules of various kinds appear in the protoplasm. Two pulsating bubbles or *contractile vacuoles* are usually to be

seen, which doubtless secure to some extent the aeration and purification of the protoplasm. In unfavourable circumstances, the amoeba can save its life by sweating off a sheath or *cyst*, within which it waits passively for better times. This passage from an active to an encysted phase is exceedingly common among the Protozoa. On attaining its maximum size, the amoeba draws itself out, and breaks into two daughter amoebae, each of which contains half of the mother nucleus. In a closely allied giant amoeba, *Pelomyxa*, a number of spore-like young are formed within the parent, and in other cases some of the processes are nipped off as buds. Two amoebae sometimes flow together and fuse in a manner which may be fairly regarded as an incipient form of sexual union (see CONJUGATION, SEX). This simple organism thus exhibits within small compass all the usual animal functions. It is contractile, irritable, and automatic; it feeds, assimilates, secretes, grows, and reproduces; and the intimate changes within the unit mass of protoplasm, in which there is no division of labour, must therefore be exceedingly complex (see PHYSIOLOGY, PROTOPLASM). There are several species of amoeba and numerous related forms, which differ in the formation of an external shell, and in similar unessential characters. All amoeboid forms with *blunt* processes are ranked together in the sub-class Lobosa, and are often included under the more general title of Rhizopoda, which comprises all the Protozoa that are predominantly amoeboid. *A. villosa* has a rough tuft at one end; *Lithamoea* is large and disk-shaped; *Pelomyxa* may attain a diameter of one-sixteenth of an inch, and a number may be artificially united into a much larger mass; *Arcella* has a somewhat horny shell, and the power of floating itself by means of secreted gas bubbles, as has been also observed in an amoeba; *Diffugia* has a membranous shell stuck over with sand grains and other foreign particles. Amoebae are to be found by allowing mud and debris from ponds to settle, and then examining patiently under the microscope.

See Leidy, *Fresh-water Rhizopods of North America* (1879), Bronn's *Protozoa*, Butschli's *Protozoa* in Bronn's *Thierreich*, and Ray Lankester's *Zoology* (1900-3).

Amoeban Verses are such as answer one another alternately, as in some of Virgil's eclogues.

Amok. See MALAYS.

Amol, a town of Persia, 76 miles N.E. of Teheran, on the Heraz, a river which flows into the Caspian; pop. 10,000.

Amomum, a genus of Zingiberaceae. See CARDAMOMS and GRAINS OF PARADISE.

Am'orites, a powerful tribe whose territory used to be defined as the country north-east of the Jordan, as far as Mount Hermon, now known from Babylonian sources to have occupied most of the habitable tracts from Mesopotamia to Lebanon. In the 14th century B.C. they passed from dependence on Egypt to vassalage under the Hittites (q.v.). In the 13th century B.C. a section of them defeated the Moabites, crossed the Jordan, and overran Canaan to the sea; but their power was broken by the Hebrews under Joshua at Gibeon. Sihon, king of Heshbon, and Og, king of Bashan (the last said to have been of gigantic size), are spoken of in Scripture as Amorite princes. The victory of Joshua did not exterminate the Amorites in Canaan; a residue became tributary under Solomon. Some recent scholars have held that they were in race akin to the Hittites, others that they were of Aryan stock; the accepted opinion of late is that they were certainly Aramaeans.

Amorphous (Gr. *a-*, 'not', *morphē*, 'form'), shapeless. In Chemistry, the term amorphous is

used to describe the uncrystallised, in opposition to the crystallised, condition of bodies. There are substances which, in certain conditions, are capable of crystallisation, but in other conditions remain amorphous. Thus, pure sugar contains carbon, which appears as an amorphous substance after the sugar has been burned in a platinum crucible. The same substance, carbon, appears in its crystallised form in the diamond.

Amory, THOMAS, an eccentric author of Irish descent, who was born about 1691 and died in 1788. His father was Councillor Amory, who went with William III. to Ireland, and was made secretary of the forfeited estates. Amory speaks of having lived in Dublin, where he knew Swift, whose sermon on the Trinity he calls in a public letter to Lord Orrery a 'senseless and despicable performance.' He was living in Westminster about 1757, with a country retreat at Hounslow. Amory lived a retired and meditative life, seldom going abroad save after dark. His *John Bunce* is a curious medley of religious and sentimental rhapsodies, descriptions of scenery, and fragments of autobiography. Latterly, his intellect is believed to have been disordered. Amory's chief works are: *Lives of Several Ladies of Great Britain. A History of Antiquities, Productions of Nature, &c.* (1755); and the *Life of John Bunce* (1756-66).

Amos, one of the so-called minor prophets of the Hebrews, was a herdsman of Tekoa, in the neighbourhood of Bethlehem, and also a dresser of sycamore trees. During the reigns of Uzziah in Judah, and Jeroboam II. in Israel (about 800 B.C.), he came forward to denounce the idolatry then prevalent. His prophetic writings contain, in the first six chapters, denunciations of the Divine displeasure against several states, particularly that of Israel, on account of the worship of idols. The three remaining chapters contain his symbolical visions of the approaching overthrow of the kingdom of Israel, and lastly, a promise of restoration. His style, remarkable for its clearness and picturesque vigour, abounds with images taken from rural and pastoral life.

Amoy, a seaport of China, in a small island of the same name (24° 40' N., 118° E.), in the province of Fukien, 30 miles E. of Chang-chow, 325 miles E.N.E. of Canton. It is among the most important of the treaty ports, and has been celebrated as a trading town for some centuries. It was one of the earliest seats of European commerce in China, the Portuguese having had establishments there in the 16th, and the Dutch in the 17th, century. In 1841 it was taken by the British, and, by the treaty of Nankin, a British consul and British subjects were permitted to reside there. The trade is now open to all nations. The imports are largely cotton and woollen goods, iron, oil, matches, beans and bean-cake, rice, flour; the exports include tea, sugar, paper, grass-cloths, and gold-leaf. The value of the imports and exports used to be far greater when the opium and China tea trades were at their height. The country round Amoy is largely depopulated. Pop. 114,000, of whom 300 or 400 are foreigners. The island of Amoy, measuring 9 by 7 miles, has 400,000 inhabitants.

Ampelidaceæ. See VITACEÆ.

Ampelodesmos. See ESPARTO.

Ampelopsis, a genus of the Vitaceæ, closely resembling the vine. The *A. hederacea* is the Virginian Creeper.

Ampère, ANDRÉ MARIE, a distinguished mathematician and physicist, was born at Lyons in 1775. The guillotining of his father in 1793 made a deep and melancholy impression on young Ampère, who sought for solace in the study of nature and

antiquity. In 1805, after he had been engaged for four years as a lecturer at Bourg and Lyons, he was called to Paris, where he distinguished himself as an able teacher in the Polytechnic School, having already begun his career as an author by his *Considérations sur la Théorie Mathématique du Jeu* (1802). In 1814 he became a member of the Academy of Sciences; in 1824, professor of Experimental Physics in the Collège de France. He died at Marseilles, June 10, 1836. Scientific progress is largely indebted to Ampère, especially for his electro-dynamic theory and his original views of the identity of electricity and magnetism, as given in his *Recueil d'Observations Electro-dynamiques* (1822), and his *Théorie des Phénomènes Electro-dynamiques* (1830). These researches prepared the way for Faraday's experiments. See his *Journal et Correspondance, 1793-1805* (7th ed. 1877); *André Marie Ampère et Jean Jacques Ampère; Correspondance et Souvenirs* (2 vols. 1875); and *St Hilaire's Philosophie des Deux Ampères* (1866).

Ampère, JEAN JACQUES ANTOINE, son of the preceding, was born at Lyons, August 12, 1800. After laying the groundwork of his comprehensive studies in Paris, he proceeded to Italy, Germany, and Scandinavia. After his return, he lectured on the history of literature at Marseilles; but, after the July revolution (1830), succeeded Andrieux as professor in the Collège de France. He was elected to the Academy in 1847; and died March 27, 1864. Ampère was deeply read in German literature; his learning was marvellously wide, and his valuable writings upon China, Persia, India, Egypt, Nubia, and his Levantine voyages, proved that the far East itself was embraced within the circle of his studies. Many of his magazine articles have been collected under the title *Littérature et Voyages* (1833). His chief works are: *Histoire Littéraire de la France avant le XII^e. Siècle* (1840); *Histoire de la Littérature Française au Moyen Age* (1841); *Histoire de la Formation de la Langue Française* (1841); *La Grèce, Rome et Dante* (1848); and *La Science et les Lettres en Orient* (1865). Deep research and judicious criticism, expressed in a clear and classical style, distinguish his various compositions.

Ampère, or AMPERE, a unit of electric current, so named in honour of André Marie Ampère (q.v.). It is one-tenth of the electro-magnetic unit of the C.G.S. system, or the current obtained by a difference of potential of one volt with a resistance of one ohm. If *A* be the value of a current in amperes, *R* the resistance in ohms, *V* the difference of potential in volts, then $A = \frac{V}{R}$. For practical

purposes it has been defined as 'the unvarying current which, when passed through a solution of nitrate of silver in water, deposits silver at the rate of 0.0011800 of a gramme per second.' See ELECTRICITY, MAGNETISM. An instrument for measuring electric currents is called an Amperemeter, Amperometre, or (contracted) Ammetre.

Ampersand, occurring also in other forms such as AMPUSAND, AMPUSSY AND, is an old name for the symbol (&) employed as a contraction for *and*, which used commonly to be placed at the end of the alphabet. It may be compared with *A per se*, *I per se*, and *O per se*. A child learning to spell or read would name the letters and then the word. For words of one letter he would add in Latin '*per se*' ('by itself'), thus '*A per se* [spells] *a*,' '*I per se* [spells] *i*.' The contraction-sign was originally simply the Latin word *et*, as can still be clearly seen in its italic form (&). Hence the Scottish name Eppersyand—that is, '*Et, per se, and*.' The other forms indicate that the symbol has come to

be regarded as representing directly not the Latin *et* but the English *and*. *A per se* often meant a thing super-excellent or unique; thus Dunbar: 'London thow arte of townes A per se;' and Gavin Douglas calls Virgil *A per se*. *O per se O*, or a *neuve Cryer of Lanthorne and Candle Light*, is the title of one of Dekker's works.

Amphibia (Gr., 'double-lived,' as living on both land and water), a class of Vertebrates between fishes and reptiles. The term was used by Linnæus to include reptiles, amphibians, and some fishes, and by Cuvier as synonymous with the title 'reptiles,' which he applied to all animals between fishes and birds. The content of the term was soon narrowed, and the amphibia were separated on the one hand from the reptiles which never breathe by gills, and on the other from the fishes which, with the exception of the Dipnoi, never breathe by lungs. And since the amphibia are more nearly related to fishes than to reptiles, Huxley united them in 1863 with the former in the general division of Ichthyoids, afterwards changed to *Ichthyopsida*, while reptiles and birds were included under the contrasted title of Sauroids or *Sauropsida*.

General Characters.—Typical amphibians, such as newts and frogs, are readily distinguished from the higher vertebrates (reptiles, birds, and mammals) by the possession of gills in larval life (and in some newt-like forms throughout life); by the absence of the fetal membranes known as Amnion (q.v.) and Allantois (q.v.) (though the latter is represented by the cloacal bladder); by the naked skin (there are dermal scales in Cæcilians) and the general absence of claws (present on three of the toes of the 'clawed toad' *Xenopus*). There are numerous internal differences of importance. Amphibians are linked to fishes by the Dipnoans, in which the swim-bladder has become a lung and the heart is on the way to become three-chambered; but from the majority of fishes the majority of amphibians are distinguished by the absence of scales, the presence of digits, the absence of fin-rays supporting the median fins if these are present. As regards the two condyles of the skull and the rod or columella which abuts against an opening (fenestra ovalis) into the inner ear, amphibians differ from all fishes. Some other very interesting acquisitions were made by amphibians in the course of evolution; thus they were the first animals to have a movable tongue and vocal chords.

Divisions of the Class.—The amphibia include four orders, three of which are represented by the newt, the frog, and the vermiform Cæcilia; while the fourth includes the Stegocephali (see LABYRINTHODONTS), now wholly extinct. (1) Forms like the newt and salamander, with long smooth bodies and persisting tails, are termed *Urodela* (Gr., 'tail distinct'). The majority are aquatic, but some are thoroughly terrestrial except at the breeding season. They usually have two pairs of limbs, but sometimes only one pair. The larval gills and gill-slits sometimes persist in adult life. Fertilisation is generally internal. All but a few of the hundred or so species are confined to the Northern Hemisphere. There are four families. The Amphiumiæ include the Giant Salamander of Japan (*Cryptobranchius japonicus* or *maximus*), which may be 5 feet long; the 'Hellbender' (*Cryptobranchius* or *Menopoma alleghaniensis*) of the eastern United States, about 18 inches in length; and *Amphiuma* means or *tridactyla* of the south-eastern states, which may attain a length of 3 feet. The Salamandridæ include the Common or Fire Salamander (*Salamandra maculosa*) of the Continent, the newts (*Triton*), the Axolotls (q.v.) (*Amblystoma*) of North and Central America, with one species in Siam. The Proteiæ include the white Olm, *Proteus anguinus*, with hidden eyes, from

the subterranean waters of Carniola, and the North American *Necturus* or *Menobranchius*. The family Sirenidæ includes a few rather degraded forms, such as *Siren lacertina*, the North American 'mud-eel,' which reaches a length of over 2 feet. Nearly related to the Giant Salamander is a famous Upper Miocene fossil, about a yard in length, which was described by Scheuchzer in 1726 in a dissertation entitled *Homo diluvii testis*. It was believed to be the remains of a man drowned in the deluge, but Cuvier recognised its newt-like characters, and Tschudi named it *Andrias scheuchzeri* in memory of its original describer and his weird fancy. (2) Forms like frogs and toads with four limbs, a short, broad body, without tail, gills, or gill-clefts in adult life, are included in the order *Anura* (Gr., 'without tail'). They have a world-wide representation, except that they are absent from almost all oceanic islands. The vertebral column consists of nine vertebrae and a post-sacral fused rod (*urostyle*). The mouth is wide, with or without a tongue, with teeth on both upper and lower jaws, or on one of them, or absent altogether. Unlike the Urodela, the Anura have large eyes with well-developed lids, and usually a tympanic cavity with a drum. They are more terrestrial than the Urodela, though there are very few exceptions to the rule that there is a prolonged larval or tadpole period spent in the water. There are about nine hundred species, classifiable in a series of families—such as the tongueless Aglossidæ (the South African 'clawed toad,' *Xenopus*; and the Surinam Toad, *Pipa*), the tree-frogs or Hylidæ, the toads or Bufonidæ, and the true frogs or Ranidæ. (3) The limbless Cæcilians (*Apoda* or *Gymnophiona*) form a small order with representatives in Central and South America, Equatorial Africa, India, and the Malay Archipelago. They are worm-like creatures, without limbs or limb-girdles, with biconcave vertebrae, with the tail very short or absent, with small functionless eyes beneath the skin, and usually with transverse rows of small calcified scales embedded in the dermis. The Cæcilians burrow near the surface of damp soil. Fertilisation is internal, and some forms are viviparous. In some respects the Cæcilians are archaic, and of living amphibians they are the nearest to the extinct Stegocephali. They are peculiar in their skull structure, in their dermic scales, in the large eggs with partial segmentation, and in the absence, so far as is known, of a larval stage breathing by gills. The embryo may show external gills within the egg, but they are lost before hatching. There is one family Cæciliidæ with about sixteen genera, such as *Ichthyophis*, *Hypogeophis*, *Cæcilia*, *Gymnophis*, and *Siphonops*. (4) The extinct Stegocephali were salamander-like forms with bony dermal plates on the dorsal surface of the skull, and usually on some other parts as well. They are the earliest known animals with five digits. They appeared in the Lower Carboniferous, and disappeared in the Upper Trias. Some of them have features which suggest reptilian affinities. The skull of *Mastodonsaurus* was over a yard in length. In many cases (Labyrinthodonts) the ivory of the teeth is folded into a mazy pattern.

Habit of Life.—Modern amphibians are the descendants of those animals which in the course of evolution began to leave the water and possess the dry land. Most of them show in their life-history a recapitulation of this great step, for they have an aquatic juvenile stage; and many of them keep in or near fresh water all their life. There is a characteristic constitutional antipathy to salt, but tadpoles and small frogs have been observed on the seashore at Manila. Many amphibians show a marked capacity for cutaneous respiration, as may be illustrated by the not infrequent occurrence of

individuals without lungs in certain species of newts, and by the hibernating frogs which breathe solely by means of the skin. As cold-blooded or poikilothermous animals, amphibians tend to approximate their body temperature to that of the surrounding world. In tropical heat the evaporation from the moist skin is a useful safeguard. Summer-sleep or aestivation may also set in. Some northern forms hibernate and may show a temperature at freezing-point, yet without succumbing unless the frost be very prolonged and the heart be frozen. The food of the adults is very varied, but usually consists of worms, insects, grubs, slugs, and other small animals. Some of the larval forms are for a time vegetarian, and cannibalism is not uncommon. Though tales of toads within stones are usually based on imperfect observation, there are some authentic instances of prolonged imprisonment in cramped quarters, both in natural and experimental conditions; and there is no doubt that prolonged fasting can be endured. Most amphibians have a very considerable regenerative capacity, being able to repair mutilated limbs or replace lost ones. This is doubtless adaptive to the frequent risk which they run in the natural conditions of their life. Amphibians are very defenceless, but some have a considerable power of colour-change, which may be sometimes useful. The secretion of the skin is sometimes nauseous or poisonous, and this has been shown by experiment to have a protective value in certain cases. In a few cases, such as *Ceratophrys dorsata*, there is a bony shield on the back made up of a number of ossifications of the inner stratum of the dermis and of the subcutaneous connective tissue.

The life of amphibians is, on the whole, at a somewhat low potential, but there is often considerable excitement at the pairing season. The males are sometimes distinguished by brighter colours, dorsal crests, dilatable resonating sacs, and different voice. In the males of a Kamerun frog (*Astylosternus robustus*) there are numerous hair-like filaments on the sides and thighs. In Anura the male embraces the female for hours or even days, and liberates the spermatozoa upon the eggs just as these are expelled. In Urodela the spermatozoa are collected in or on a gelatinous packet or spermatophore, which is formed in the cloaca of the male. The packet is deposited by the male and secured by the cloacal lips of the female. There may be sexual embrace (amplexus) or not, but there is no true copulation except in the limbless Cæcilians. The eggs are usually numerous in Anura, but comparatively moderate in number in the others. There may be three thousand in the Grass Frog (*Rana temporaria*), five thousand in the toad (*Bufo vulgaris*), and ten thousand in the Edible Frog (*R. esculenta*). They have an investment of jelly, and may be laid in strings or singly. Some Urodela and Apoda are viviparous.

Development and Life-history.—The segmentation of the ovum is total and unequal, except in the Cæcilians, where it is partial or meroblastic. In all Anura, and in most of the others, the development takes place outside the body of the mother. As we have noted, there is viviparity in some Urodela and Cæcilians. Thus the Alpine Salamander (*Salamandra atra*) produces two young ones at a time, which undergo their whole metamorphosis before birth. In the majority of cases the young pass through an aquatic larval stage and show various peculiarities specially adapted to this period. There are three external gills on each side, which are formed before the gill-slits open. These are the only gills found in the Urodela, but in the larvæ or tadpoles of Anura a fold of skin (operculum) grows backwards, overlapping the gill-clefts and the gills. Thereafter the gills disappear and

their place is taken by a second set, which are called internal, though they are really of the same nature as the first set—branched skin-gills covered with ectoderm. In fact, the gills of amphibians are comparable to the external gills of the Dipnoi and Polypterus, not to the ordinary pharyngeal, endoderm-covered gills of ordinary fishes. In the course of development the gills and gill-clefts disappear, except in a few Urodela (perennibranchiate) in which some of them persist. Among the other larval features may be noticed the adhesive organs, badly called suckers; the lateral line sense-organs like those of a fish (persisting only in perennibranchiate forms); the fish-like circulation; and

The Surinam Toad (*Pipa americana*).

the horny armature of the mouth in the tadpoles of Anura. In a number of cases there is a curious retention of larval characters beyond the normal period. This is known as 'neoteny' ('véos, 'young,' 'relax,' 'stretch'), and may be partial, as is sometimes seen in the common frog and toad, or total, as in some newts and the Axolotl, where the permanently larval form becomes sexual. There are many peculiarities in the reproductive habits of amphibians, which may be illustrated by a brief reference to some of the instances of special parental care.

a, segmented ovum of frog, stage with sixty-four cells (from Balfour, after Ecker); b, embryo within membrane; bl, the blastopore or gastrula mouth (from Balfour, after Remak); c, tadpole with external gills (g); m, mouth; s, adhesive organs.

In the Surinam toad (*Pipa americana*) the large ova are placed on the back of the female (the male apparently helping); a little skin pocket is formed around each of them, and thence they are hatched as miniature toads. In *Nototrema* the female has a dorsal pouch opening backwards, and into this the male pushes the eggs with his hind-legs. In the Nurse-toad (*Alytes obstetricans*) the male winds the strings of ova about his hind-legs, buries himself in damp earth until the time comes for hatching, when he plunges into water and is freed from his living burden. In *Rhinoderma darwini*, the male takes the large eggs (5-15)

into the resonating sacs, which enlarge as development proceeds, and eventually small frogs escape from the mouth.

Life-history of Frog :

1, recently hatched tadpoles about natural size; 2, with external gills; 2a, same enlarged; 3 and 4, enclosure of gills; 5, hind-limbs visible; 6, after skin-casting, both pairs of legs visible; 7, atrophy of tail; 8, young frog. (From Mivart)

See Hans Gadow, 'Amphibians and Reptiles,' vol. viii. of *Cambridge Natural History* (1901); G. A. Boulenger, *British Museum Catalogue of the Batrachia* (1882); *Reptiles, Amphibia, &c.*, edited by J. T. Cunningham (1912), section on 'Amphibia,' by Boulenger and Cunningham; Sedgwick, *Student's Textbook of Zoology*, vol. ii. (1905).

Amphibole, the name of a group of minerals which are essentially silicates of lime and magnesia; but these bases are often partly replaced by alumina, and oxides of iron and manganese. The most important minerals in this group are Tremolite, Actinolite, Nephrite (Jade), and Hornblende. Asbestos and its varieties are forms of Tremolite and Actinolite. Many of these occur as fine hair-like filaments, readily separable from each other (*Amianthus*, mountain-flax); in other cases the filaments or fibres are more or less firmly interwoven, giving rise to products which closely resemble the substances after which they are named—mountain-leather, mountain-cork. See separate articles on the minerals named.

Amphictyon'ic Council, a celebrated council of the states of ancient Greece. An *amphictyony* meant originally an association of several tribes for the purpose of protecting some temple common to them all, and for maintaining worship within it, and it was only later that it acquired also a political importance. Its members were called *amphictyons* ('the dwellers around'). Such associations existed at Argos, Delos, and elsewhere; but the most important was that at Anthela, near Thermopylae, the seat of which was transferred later to Delphi through Dorian influence. The members of this league were twelve in number, and were, according to Æschines, the Thessalians, Boeotians, Dorians, Ionians, Peræthians, Magnesians, Locrians, Eteans, Phthiotis, Malians, and Phocians, and the Dolopians who are mentioned in other accounts. The members of this confederation bound themselves by an oath not to destroy any city of the Amphictyons, nor cut off their streams in war or peace, and to employ all their power in punishing those who did so, or those who pillaged the property of the god, or injured his temple at Delphi. So excellent an oath was very

indifferently kept. In the primitive period of Greek history it had a beneficial and civilising influence; but its more important interferences in the affairs of Greece were directly contrary to the spirit of its institution. The first of these was the so-called *sacred war*, waged from 595 to 585 B.C., against the Phocian city of Crissa. The second *sacred war*, from 355 to 346 B.C., gave occasion to the fatal interference of Philip of Macedon in the affairs of Greece (see PHILIP); and a third *sacred war*, instigated by Philip, was but the prelude to the victory of Chæronæa, so fatal to Greek liberty.

Amphigastria, scales or rudimentary leaves on the under side of a liverwort.

Amphineura are primitive gasteropods. See CHITON, GASTEROPODA, MOLLUSCA.

Amphi'on, son of Zeus and Antiope, brought up with his twin-brother Zethus on Mount Cithæron, where he practised singing to the lyre. When the brothers grew up and discovered their descent, they marched against Thebes, and put to death its king Lycus and his wife Dirce for having treated their mother with cruelty. They then fortified Thebes by a wall, to make which the stones moved of their own accord to the music of Amphi'on's lyre. He married Niobe, and killed himself from grief when all his children were destroyed by Apollo.

Amphioxus, or LANCELET, a name applied to the members of a class (Cephalochorda) of primitive vertebrate animals, abundantly represented off the sandy coasts of warm and temperate seas. Lancelets can hardly be called fishes, for the structural differences between them and fishes are greater than those separating mammals from birds. That they are within the Vertebrate or Chordate series is plain from the nature of their embryonic development, and also from the presence of a dorsal nerve-cord, of a dorsal supporting axis or notochord, and of gill-slits. They can on occasion swim swiftly, but they spend most of their time burrowing in the sand, or resting in it with their mouths protruding. Their food consists of microscopic organisms and

Amphioxus (from Haeckel).

organic particles. The class includes two chief genera: (1) Branchiostoma, with the subgenera Amphioxus and Dolichorhynchus; and (2) Heteropleuron, with the subgenera Paramphioxus, Epigonichthys, and Asymmetron. From fishes they are widely removed by a number of negative characters—the absence of limbs, skull, jaws, differentiated brain, sympathetic nervous system, eye, ear, definite heart, spleen, and genital ducts. There is a dorsal tubular nerve-cord, with numerous regularly arranged 'eye-spots' on each side. The notochord or supporting rod of turgid cells is unsegmented and persists throughout life, instead of being a transient structure, giving place to the vertebral column, as in most vertebrates. It projects in a unique fashion in front of the anterior end of the nerve-cord; hence the technical name of the class, Cephalochorda. In the adult there are very numerous gill-slits, which open from the pharynx into a remarkable chamber—the aboral or peribranchial cavity. This communicates with the exterior by an atriopore. In the larval form the gill-clefts open at first directly to the exterior. The body-wall is built up of over fifty muscle-blocks or myotomes, separated by zigzag connective-tissue septa. The living animal is very translucent. There are numerous separate kidney-

tubes, and numerous, segmentally arranged, reproductive organs without ducts. The early embryo swims in the open sea. The larva is strangely asymmetrical, and the larval period is prolonged. In fact, the type is full of peculiarities, and though an offshoot from the primitive vertebrate stock, it is highly specialised on a line of its own. See E. Ray Lankester, *Contributions to the Knowledge of Amphioxus* (1889), and Arthur Willey, *Amphioxus and the Ancestry of the Vertebrates* (1894).

Amphipods, an order of small sessile-eyed crustaceans, with laterally compressed bodies, and long abdomen with three pairs of swimming appendages in front, and behind these three backward turned springing feet. The thoracic or anterior legs bear the gills. The order includes a great number of common forms—e.g. the familiar Sandhopper, q.v. (*Talitrus saltator*); another very frequent genus, *Orchestia*, sometimes much more terrestrial than the former; the abundant Gammarus of running water; the wood-boiling Limnoria and Chelura; the blind Niphargus of underground fresh water; the quaint Spectre or Skeleton Shrimp, q.v. (*Caprella*); and many more. See CRUSTACEA.

Amphipolis, a town of Macedonia, on the river Strymon, about 3 miles from the sea. The river flowed almost round the town, nearly forming a circle, whence its name *Amphi-polis* ('around the city'). Taken by the Athenians in 437 B.C., it fell into the hands of Philip of Macedon in 358; and afterwards, under the Romans, became the capital of their four Macedonian provinces. It is mentioned in Acts xvii.

Amphisbæna, a general name for the members of a family (*Amphisbænidae*) of worm-like, limbless lizards, which lead a burrowing life, and feed on insects and worms in the ground. They are widely distributed in the warmer parts of America and Africa, and four are Mediterranean. The soft skin is marked by little squares, vestiges of scales which are developed on the head only. The eyes and ears are hidden; the skull is very strong; the tail is very short. See LIZARDS.—The name is taken from the fabulous two-headed serpent of the Greeks (*amphis*, 'both ways'; *bainō*, 'go').

Amphissa (mod. *Salona*), a town of Locris, destroyed by Philip in the third Sacred War.

Amphitheatre, a spacious building, generally oval in form, used by the Romans for exhibiting gladiatorial combats, fights of wild beasts, and other spectacles. The amphitheatre differed from a theatre for dramatic performances (*theatrum*) in this, that whereas the theatre had only a semicircle of seats fronting the stage, the amphitheatre was entirely encircled by them; hence the name of amphitheatre (Gr. *amphí*, 'all round'). At first these erections were of wood, and merely temporary, like a modern race-stand. They seem, however, to have been of enormous size, as Tacitus mentions one at Fidenæ, during the reign of Tiberius, whose collapse is said to have caused the death or injury of 50,000 spectators. Amphitheatres of stone had begun, however, to be erected at an earlier period than this, the first having been built in 31 B.C. at the desire of Augustus. The Flavian amphitheatre at Rome, known as the Colosseum from its colossal size, was begun by Vespasian, and finished by Titus 80 A.D., ten years after the destruction of Jerusalem. It was the largest structure of the kind, and is fortunately also the best preserved. It covers about five acres of ground, and was capable of seating 87,000 spectators. Its greatest length is 612 feet, and its greatest breadth 515, the corresponding figures for the Albert Hall in London being 270 and 240. On the occasion of its

dedication by Titus, 5000 wild beasts were slain in the arena, the games lasting nearly a hundred days. The exterior is about 160 feet in height, and consists of three rows of columns, Doric, Ionic, and Corinthian, and, above all, a row of Corinthian pilasters. Between the columns there are

Colosseum—Exterior.

arches, which form open galleries throughout the whole building; and between each alternate pilaster of the upper tier there is a window. Besides the *podium*, there were three tiers or

Colosseum—Interior.

stories of seats, corresponding to the external stories. The first of these is supposed to have contained twenty-four rows of seats; and the second, sixteen. These were separated by a lofty wall from the third story, which contained the populace. The *podium* was a gallery surrounding the arena, in which the emperor, the senators, and vestal virgins had their seats. The building was covered by a temporary awning or wooden roof, the *velarium*. The open space in the centre of the amphitheatre was called *arena*, the Latin word for sand, because it was covered with sand or sawdust during the performances. The taste for the excitement of the amphitheatre which existed at Rome, naturally spread to the provinces, and large amphitheatres were erected not only in the provincial towns of Italy, as at Capua, Verona, Pompeii, Pozzuoli, &c., but at Arles, Nîmes, and Fréjus, in France; at Italica, near Seville, in Spain; and even in England, at Cirencester, Silchester, and Dorchester.

Amphitrité, a sea-goddess in Greek Mythology, daughter of Nereus, or of Oceanus, and wife of Poseidon. When the latter demanded her in marriage, she fled to Mount Atlas, but was discovered by a dolphin, which Poseidon had sent after her, and borne back to him. In sculpture, she is often represented sitting next to Poseidon, or drawn by Tritons.

Amphit'ryon, in Greek Mythology, a king of Tiryns, son of Alcæus, and husband of Alcmene. During his absence from home in order to punish the murderers of his wife's brothers, Alcmene was visited by Zeus in the disguise of Amphitryon, who himself returned home next day. She became the mother of Hercules by Zeus, and of Iphicles by Amphitryon. The story has been treated by Plautus in his *Amphitruo*, and after him by Molière in his *Amphitryon*, a very free adaptation of his original. Here his hero was supposed to be M. de Montespan, husband of the new mistress of Louis XIV. In the latter, Amphitryon gives a great dinner; hence the name has become a common term for a host or entertainer to dinner.

Amphiuma, a North American tailed amphibian, which loses the external gills of its youth. It thus belongs to the caducibranch group of the order Urodela. The form is roughly eel-like, and about 2 feet long; the legs, which are small and distant, have two or three toes; the eyes are covered with skin; and there are numerous teeth. On each side of the somewhat narrowed neck there is a gill slit, partly covered with a fold of skin. This type, like other *Derotremata*, as they are called, is thus half-way between those amphibians like Proteus (q.v.), which permanently retain their external gills, and those like the newt, in which the gills entirely disappear in the adults, and the clefts close up. *A. means* is found in the southern and south-western states burrowing in the mud—e.g. in the ditches of the rice-fields. It feeds on small fish, molluscs, and insects. The negroes call it the Congo snake, and erroneously regard it as venomous.

Am'phora (Lat., from Gr. *amphoreus*, shortened from *amphiphoreus*), among the Greeks and Romans, a large vessel, usually made of clay, with a narrow neck and two handles, and often ending in a sharp point below, for being inserted in a stand or in the ground. It was chiefly used for preserving various liquids, especially wine, and was frequently decorated with paintings. There is also evidence that *amphoræ* were employed as cinerary urns and as coffins. The Greek amphora contained about nine English gallons; the Roman, about six.

Amplitude, in Astronomy, is the distance of a heavenly body, at the time of its rising or setting, from the east or the west point of the horizon. When the sun is in the equator (i.e. at the time of either equinox), he rises exactly east, and sets exactly west, and therefore has no amplitude. His amplitude is at its maximum at midsummer, and again at midwinter; and that maximum depends upon the latitude of the place, being $23\frac{1}{2}^\circ$ at the equator, and increasing to the Arctic Circle, where it becomes 90° . The amplitude of a fixed star remains constant all the year round.

Ampulla, a kind of bottle used by the Romans for the preservation of liquids. It was made either of earthenware or glass, and sometimes, though very rarely, of costlier materials. Great numbers of such vessels have found their way into collections of antiquities. They are generally 'bellied'—i.e. approaching to globular, narrowing towards the mouth, and provided with two handles. They are frequently mentioned in connection with the baths of ancient times. The *ampulla olearia* was a 'bottle of oil' which the Roman took with him when he went to the bath, and with which he anointed himself after his ablutions. Sometimes the oils were perfumed. The *ampulla Remensis* (Fr. *la sainte ampoule*) was the name of the famous vessel containing the unguent with which

the French kings were anointed at their coronation at Rheims. The ampulla, a vessel for the coronation oil in the English regalia, is in the shape of an eagle. See REGALIA.

Amputation (Lat. *amputare*, 'to lop' or 'prune') is the cutting off of a part which, by its injured or diseased condition, endangers, or may endanger, the safety of the whole body. The amputation of a limb was in ancient times attended with great danger of the patient's dying during its performance, as surgeons had no efficient means of restraining the bleeding. They rarely ventured to remove a large portion of a limb, preferring to allow partial separation first to take place by gangrene, when they knew there would be less bleeding; the smaller parts they chopped off with a mallet and chisel; and in both cases had hot irons at hand with which to sear the raw surfaces, boiling oil in which to dip the stump, and various resins and mosses, supposed to possess the power of arresting hemorrhage.

The desired power of controlling bleeding by simpler means had been known to the ancient surgeons of Rome and Byzantium, but was reintroduced by Ambrose Paré, surgeon to the French court, in the 16th century, who grasped the ends of cut vessels with forceps and tied them with thread. The Tourniquet (q.v.) was invented in 1674 by Morel, and improved by Petit in the next century. The ancient surgeons endeavoured to save a covering of skin for the stump, by having the skin drawn upwards by an assistant, previously to using the knife. In 1679 Lowdham of Exeter suggested cutting semicircular flaps on one or both sides of a limb, so as to preserve a fleshy cushion to cover the end of the bone. Both these methods are now in use, and are known as the 'circular' and the 'flap' operations: the latter is most frequently used in this country.

A 'flap' amputation is performed thus: The patient being placed in the most convenient position, an assistant compresses the main artery of the limb with his thumb, or a tourniquet is adjusted over it. Another assistant supports the limb. The surgeon with one hand lifts the tissues from the bone, and transfixing them with a long narrow knife, cuts rapidly downwards and towards the surface of the skin, forming a flap; he then repeats this on the other side of the limb. An assistant now draws up these flaps, and the knife is carried round the bone, dividing any flesh still adhering to it. The surgeon now saws the bone. An expert surgeon can remove a limb thus in from thirty to sixty seconds. He then, with small forceps, seizes the ends of the large arteries, and while he draws them slightly from the tissues, an assistant ties them with threads. All the vessels being secured, the tourniquet is removed, the flaps are stitched together, and the wound is dressed.

The question *when* amputation of a limb is necessary, is often, especially after an accident, one of the most difficult in surgery. The chief indications for it in these cases are—very extensive destruction or laceration of the skin; injury to the large vessels or nerves; severe splintering of the bones. The diseases most commonly requiring it are—disease of bones or joints, especially when the discharge from it threatens to exhaust the patient; tumours, especially cancer and sarcoma, which cannot otherwise be removed; and gangrene.

Amraoti (*Umrvati*), capital of a great cotton-producing district in British India, is the principal cotton-mart in Berar; pop. 34,000.

Amravati (*Amaravati*), a village of the Madras Presidency, near the head of the delta of the Kistna, with the ruins of a great Buddhist tope or *stupa*, once covered with rich sculptures.

Amritsar, headquarters of Amritsar district, Lahore division of the Punjab. It is the religious metropolis of the Sikhs, a distinction which, along with its name (literally, 'pool of immortality'), it owes to its sacred tank, in the midst of which stands the marble temple of the Sikh faith. Founded in 1574, but all of it more recent than 1762, it is, next to Delhi, the richest and most prosperous city in northern India, with manufactures of Kashmir shawls, cotton, silks, &c. Pop. 160,000.

Amroha, a town in the United Provinces of India, 20 miles NW. of Moradabad; pop. 40,000.

Amrom, or **AMRUM**, one of the North Frisian islands of Germany, 15 miles off the west coast of Sleswick, and SW. of Fohr. It is low, sandy, grassy, and excellent for golf.

Amru Ibn Aass, an Arab soldier, joined the Prophet about 629, distinguished himself during the conquest of Palestine, and in 638 undertook the conquest of Egypt with a modest force of 4000 Arabs, which grew twentyfold through success. In 641 he took Alexandria (q.v.) after a fourteen months' siege, during which he had lost before the walls 23,000 men. The conquest of Egypt opened to the Arabs the path to conquests westwards, and Amru himself overran Tripoli and Barca. He died as governor of Egypt in 664.

Amstel, SAMUEL, engraver after Raphael and Thorwaldsen, was born at Schinznach in Switzerland in 1791, and was professor of engraving at Munich, where he died, 18th May 1849.

Amsterdam, the historic and commercial capital of the Netherlands, though not the seat of the government (see **HAGUE**), is situated at the influx of the Amstel to the IJ or Y (pron. *eye*), an arm (now mostly drained) of the Zuider-Zee, 44½ miles NNE. of Rotterdam by rail. It is divided by the Amstel and numerous canals into a hundred small islands, connected by more than 300 bridges. Almost the whole city, which extends in the shape of a crescent, is founded on piles driven 40 or 50 feet through soft peat and sand to a firm substratum of clay. At the beginning of the 13th century it was merely a fishing-village, with a small castle, the residence of the Lords of Amstel. In 1296, on account of its share in the murder of Count Floris of Holland, the rising town was demolished; but in 1311, with Amstelland (the district on the banks of the Amstel), it was taken under the protection of the Counts of Holland, and from them received several privileges which contributed to its subsequent prosperity. In 1482 it was walled and fortified. After the revolt of the seven provinces (1566), it speedily rose to be their first commercial city, a great asylum for the Flemish Protestants; and in 1585 it was considerably enlarged by the building of the New Town on the west. The establishment of the Dutch East India Company (1602) did much to forward the well-being of Amsterdam, which twenty years later had 100,000 inhabitants. War with England so far reduced commerce that, in 1653, 4000 houses stood uninhabited. Amsterdam had to surrender to the Prussians in 1787, to the French in 1795; and the union of Holland with France in 1810 entirely destroyed its foreign trade, while the excise and other new regulations impoverished its inland resources. The old firms, however, lived through the time of difficulty, and in 1815 commerce again began to expand—an expansion greatly promoted by the opening in 1876 of a new waterway between the North Sea and the city (see **CANAL**), more direct than the North Holland Canal (see **ZUIDER-ZEE**) to The Helder (1825).

The city has a fine appearance when seen from

the harbour, or from the high bridge over the Amstel. Church towers and spires, and a perfect forest of masts, relieve the flatness of the prospect. The old ramparts have been levelled, planted with trees, and formed into promenades. In the south are modern houses and streets and the Vondel Park. Tramways radiate from the Dam, the centre of the city. There is railway communication with all parts of the country and of Europe. Rich grassy meadows surround the city. On the west side are a great number of windmills for grinding corn and sawing wood. The three chief canals—the Heeren-gracht, Keizersgracht, and Prinsengracht—run in semicircles within each other, and are from 2 to 3 miles long. On each side of them, with a row of trees and a carriage-way intervening, are handsome residences. The building-material is brick; and the houses have their gables towards the streets, which gives them a picturesque appearance. The defences of Amsterdam now consist in a row of detached forts, and in the sluices, several miles distant from the city, which can flood, in a few hours, the surrounding land. The docks of Amsterdam and the North Sea Canal were enlarged in 1907, but further extensions were called for by 1913, when 2245 ships, with a tonnage of 4,177,951, cleared the port. Leading imports are coffee, cocoa, tobacco, tea, rubber, and other colonial produce, and coal.

The population, which, from 217,000 in 1794, sank to 180,000 in 1815, rose steadily to 650,000 in 1920, of whom the majority belong to the Dutch Reformed Church. Of the remainder about 100,000 are Catholics, 50,000 German Jews, and 5000 Portuguese Jews. The chief industries are sugar-refining, engineering, cutting and polishing diamonds and other precious stones, shipbuilding, fishing; and there are manufactories of sails, ropes, tobacco, silks, gold and silver plate and jewellery, colours, and chemicals; breweries, distilleries; with export houses for corn and colonial produce. Cotton-spinning, book-printing, and type-founding are also carried on. The present Bank of the Netherlands dates from 1824, Amsterdam's famous bank of 1609 having been dissolved in 1796.

The former *Stadhuis* ('Townhouse'), converted in 1808 into a palace for King Louis Bonaparte, and still retained by the reigning family, is a noble structure. Built by Van Kampen in 1648-55, and raised upon 13,659 piles, it extends 282 feet in length, by 235 feet in breadth, and is surmounted by a round tower rising 182 feet from the base. It has a hall, 120 feet long, 57 wide, and 90 high, lined with white Italian marble—an apartment of great splendour. The cruciform *Nieuwe Kerk* (New Church), a Gothic edifice of 1408-14, is the finest ecclesiastical structure in the city, with a splendidly carved pulpit, and the tombs of Admiral de Ruyter, the great Dutch poet Vondel, and various other worthies. The Old Church (*Oude Kerk*), built in the 14th century, is rich in painted glass, has a grand organ, and contains several monuments of naval heroes. Literature and science are represented by two universities (one supported by the municipality, the other a Free University), by academies of arts and sciences, by museums and picture galleries, a palace of national industry, fine zoological gardens, a botanical garden, several theatres, &c. The Ryksmuseum contains a truly national collection of paintings, its choicest treasure being Rembrandt's 'Night-guard.' Rembrandt (q.v.) made Amsterdam his home; and his statue (1852) now fronts the house he occupied. Spinoza was a native.

Amsterdam, a city of New York, is 33 miles NW. of Albany, has woollen and other kinds of factories, foundries, and machine-shops, an academy, and a hospital; pop. 34,000.

Amsterdam, NEW, a volcanic, wooded islet, 25 sq. m. in area, in 37° 50' S. lat. and 77° 30' E. long., midway between the Cape of Good Hope and Tasmania. It belongs to France, like St Paul (q.v.).

Amu-Daria. See OXUS, KHIVA.

Amulet, any object worn as a charm. It is often a stone, or piece of metal, with an inscription or some figures engraved on it, and is generally suspended from the neck, and worn as a preservative against sickness or witchcraft. Its origin, like its name, seems to be oriental. The ancient Egyptians had their amulets, sometimes forming necklaces. Among the Greeks, such a protective

Egyptian Amulet.

charm was styled *phylacterion*. Pliny gives the Latin name, *amuletum*, a word of unknown origin. It has been conjecturally compared with the modern Arabic *himālah-at* (literally 'a carrier,' 'bearer'), now applied to a shoulder-belt or cord, frequently used to secure a small Koran or prayer-book on the breast, regarded as an amulet; but the resemblance between this word and the Latin *amuletum* is purely accidental. The phylacteries of the Jews (see Matt. xxiii. 5), slips of parchment on which passages of the Law were written, were evidently worn as badges of piety by the Pharisees; but were also regarded as wholesome preservatives from evil spirits, and from all manner of harm. From the heathen, the use of amulets passed into the Christian Church, the usual inscription on them being *ichthys* (the Greek word for a fish), because it contained the initials of the Greek words for Jesus Christ, Son of God, Saviour. Among the Gnostic sects, Abraxas stones (q.v.) were much used. Amulets soon became so common among Christians that, in the 4th century, the clergy were interdicted from making and selling them on pain of deprivation of holy orders; and in 721, the wearing of amulets was solemnly condemned by the church. Among the Turks and the tribes of Central Asia, every person considers it necessary to wear a preservative charm. With the spread of Arabian astronomy, the astrological amulet or Talisman (q.v.) of the Arabs found its way to Europe. Among amulets in repute in the middle ages were the coins attributed to St Helena, the mother of Constantine. These and other coins marked with a cross were thought specially efficacious against epilepsy, and are generally found perforated, for the purpose of being worn suspended from the neck.

Amundsen, ROALD, a Norwegian polar explorer (born in 1872), the first to navigate the North-west Passage (1906) and to reach the South Pole (14th December 1911), attempted the North Pole by air (1925). See POLAR EXPLORATION.

Amur (Amoor, or Sakhalin), a Siberian river formed by the junction (about 53° N. lat. and 121° E. long.) of the Shilka and the Argun, which both come from the south-west—the former rising in the foothills of the Yablonoi Mountains. From the junction, the river flows first south-east and then north-east, and, after a total course of 3060 miles, falls into the Sea of Okhotsk, opposite the island of Sakhalin. Its main tributaries are the Sungari and the Ussuri, both from the south. The area of the river-basin is estimated at 750,000 sq. m. The

Amur is navigable, and carries 500 or 600 vessels. Sandbanks, however, make Nikolaevsk (q.v.), near its mouth, difficult of approach from the sea; ice restricts the navigation season to five months; and summer brings severe floods. Salmon and caviare from the Lower Amur and estuary are sent to Russia in increasing quantities.

From as early as 1636 Russian adventurers made excursions into the Chinese territories of the Lower Amur. In 1666 they built a fort at Albazin, and succeeded in navigating from that fort to the mouth of the river. In 1685 the fort was taken and destroyed by the Chinese, but was retaken promptly by the Russians, who again, in 1689, abandoned it and the whole of the Amur to the Chinese. But soon fur-hunters of Siberia, Russian traders, and adventurers, encouraged by government, continued to pursue their vocations on Chinese ground. In 1854-56 two military expeditions were conducted by Count Muiraviev, who twice descended the river, unopposed by the Chinese, and established the stations of Alexandrovsk and Nikolaevsk. In 1858 China agreed to the treaty of Tientsin, by which the boundaries of Russia and China were defined. The left bank of the Amur, and all the territory north of it, became Russian; and below the confluence of the Ussuri, both banks. In 1860 the more temperate territory east and south of the Ussuri was acquired by treaty. Japan, which obtained southern Sakhalin in 1909, sought a footing on the Amur after the Russian revolutions. The Amur region became part of the 'Far Eastern Republic,' which included also Transbaikalia.

The *Pri-Amur* or Amur region of Eastern Siberia is bounded on the north by the Stanovoi Mountains; it has an area of about 980,000 sq. m., with over 1,000,000 inhabitants, and was divided in imperial times into the Maritime Province (Primorskaya), Kamchatka, (north) Sakhalin or Saghalien, and Amur Province, all under a governor-general at Khabarovsk. The Trans-Siberian railway greatly increased Russian immigration; in 1902-12 over 177,000 settlers arrived. The principal ports are Vladivostok, Nikolaevsk, Petropavlovsk, and Alexandrovsk. The chief exports are soya beans (from Manchuria), timber, fish, furs, skins, and gold; coal, zinc, and silver-lead are worked.

The *Amur Province* (area 154,780 sq. m.) lies inland, north of the Amur, over against Heilung and between Transbaikalia and Khabarovsk. The capital is Blagovestchensk (pop. 63,000). The province is richly timbered and contains large level tracts of fertile land. Gold is mined. Tunguses occupy the high plateaus, Russian settlers the river-side. Communication till 1915 was by the Amur to the sea or by the Shilka to Sryetensk on the Trans-Siberian railway. Great developments, however, are expected to result from the completion of the Amur railway. This railway was constructed in 1907-15, solely by Russian labour, notwithstanding great engineering difficulties and terrible extremes of climate, carrying the Trans-Siberian line from Transbaikalia entirely through Russian territory, passing north of the Shilka and Amur, and crossing the latter to Khabarovsk (by a bridge 7038 feet long), whence the Ussuri railway runs to Vladivostok. See also SIBERIA.

Amurath, or MURAD, the name of five sultans of Turkey (q.v.).

Amurnath ('Immortal Lord'—i.e. Siva), the name of (1) a village in Kalyau talulla (Bombay) with a very old Hindu temple; (2) a cave in Kashmir believed to be Siva's residence.

Amyclæ, (1) an ancient town of Laconia, on the eastern bank of the Eurotas, 2½ miles SE. of Sparta. It was the home of Castor and Pollux, the 'Amyclæan brothers.' It was conquered by the Spartans

only before the first Messenian war.—(2) An ancient town of Latium, which claimed to have been built by a colony from the Greek Amyclæ.

Amygdalææ, a sub-order of Rosacæ (q.v.). See also ALMOND, CHERRY, PEACH, NECTARINE, PLUM.

Amygdalin, $C_{20}H_{27}NO_{11} \cdot 3H_2O$, is a crystalline principle existing in the kernel of bitter almonds, the leaves of the *Prunus lauro-cerasus*, and various other plants, which, by distillation, yield hydrocyanic acid. It is obtained, by extraction with boiling alcohol, from the paste or cake of bitter almonds, which remains after the fixed oil has been separated by pressure. When obtained pure, it has a sweetish, somewhat bitter taste, and is not poisonous, and when treated with alkaline solvents, ammonia is expelled, and amygdalic acid, $C_{20}H_{25}O_{12}$, is produced. Its most remarkable change is, however, that which is noticed in the article Volatile Oil of Almonds (q.v.), and which may be thus briefly stated. When the bruised almond kernel, or almond paste, is brought in contact with water, the peculiar odour of bitter almonds is almost immediately evolved; and in twenty-four hours all traces of amygdalin will have disappeared, its place being taken by essential oil of almonds, hydrocyanic acid, sugar, and formic acid. This transformation is due to the presence of a peculiar nitrogenous matter called Emulsin (q.v.), or synaptase, which sets up a kind of fermentation.

Amygdaloid (Gr. *amygdalē*, 'an almond'), an igneous crystalline or, as the case may be, vitreous rock (lava), containing numerous cells, which owe their origin to the segregation and expansion of steam, with which all lavas are more or less charged at the time of their eruption. The cells vary in size from mere pores up to cavities several inches or even feet in diameter—these last, however, being exceptional, and when they do occur, quite sporadic. The cells are generally flattened or drawn out in the direction of flow of the lava, and are frequently filled with mineral matter (amygdules), subsequently introduced by infiltrating water. This is the origin of many of the agates and so-called 'Scotch pebbles' of jewellers. As cells and cellular structure occur in many different kinds of igneous rock, the term *amygdaloid* no longer denotes a rock-species, and has therefore fallen into disuse. It is now only employed in the adjectival form, *amygdaloidal*, as indicating a cellular or slaggy-like structure, in which the pores and cells are more or less filled up with mineral matter.

Amyl, C_5H_{11} , is the fifth in the series of alcohol radicals whose general formula is C_nH_{2n+1} , and of which methyl and ethyl are the first two members. It is obtained by heating amyl-iodide with an amalgam of zinc in a closed tube at a temperature of about 350° F. (177° C.), and is one of the natural products of the distillation of coal. As thus obtained, it represents two molecules of the radical united together, and usually goes by the name *diamyl*, $(C_5H_{11})_2$. The single molecule, C_5H_{11} , has not been produced. *Diamyl* is a colourless liquid, with a specific gravity of .770 at 52° F. (11° C.), and a boiling-point of about 316° F. (158° C.). It has an agreeable smell and burning taste. It enters into a large number of chemical compounds, most of which—as, for instance, bromide, chloride, iodide, &c.—are derived from amyl alcohol, which bears precisely the same relation to amyl that ordinary alcohol bears to ethyl, C_2H_5 . Amylic alcohol is sufficiently described in the article FUSEL OIL, which is the name given to the crude alcohol. It seems invariably to accompany ordinary alcohol when the latter is prepared by fermentation, and apparently occurs in largest quantity in those

liquids which remain most alkaline during fermentation.

AMYL, NITRITE OF, $C_5H_{11}NO_2$, a valuable drug which must not be confounded with *Nitrate of Amyl*, may be prepared by the action of nitric acid on fusel oil (amyl alcohol). It is a pale yellowish liquid, with an ethereal fruity odour, the vapour of which, when inhaled, even in very small quantity, causes violent flushing of the face and a feeling as if the head would burst. It is a very powerful remedy in all convulsive diseases, and is of special value in angina pectoris, as well as in asthma. Owing to its volatile nature it is usually kept in small glass globes containing from two to five drops, one of which, when crushed in the handkerchief, and the vapour breathed, will often give immediate relief.

Amyloid (Gr. *amylon*, 'starch') is a term used in Chemistry and Botany, and generally equivalent to 'starchy.' Amyloids are substances like starch, dextrine, sugar, gum, &c., which consist of carbon, hydrogen, and oxygen, the latter two being always in the proportion in which they occur in water, H_2O . The animal body, chemically considered, is a mixture of Proteins (q.v.), amyloids or carbohydrates, and Fats (q.v.), plus water and mineral constituents, and the normal food always contains these constituents. Of the three items, proteins are, however, absolutely essential, amyloids and fats only desirable accessories. In the human body the most important carbohydrates are glycogen, $C_6H_{10}O_5$; grape-sugar or dextrose, $C_6H_{12}O_6$; maltose, $C_{12}H_{22}O_{11}$; and milk-sugar, $C_{12}H_{22}O_{11}$. See ANIMAL CHEMISTRY. A compound radical called *Amyl* (q.v.) is formed by the decomposition of starch in a peculiar fermentation—the *amyllic fermentation*—but to it the term amylaceous has no reference.

Amyot, JACQUES (1513-93), a French classical scholar who, born at Melun of humble parentage, rose to be professor of Latin and Greek at Boulogne, tutor to Henry II.'s sons, and bishop of Auxerre. His translations of Plutarch, Diodorus, &c. are remarkable for their fine style. Sir Thomas North (q.v.) Englished Amyot's version of Plutarch's *Lives*.

Amyot, JOSEPH (1718-94), a French Jesuit missionary in China who compiled a Tatar-Manchu dictionary and memoirs on Chinese history, science, and art.

Amyridacææ, a sub-order of the Terebinthacææ of some botanists, trees and shrubs remarkable for the abundance of their fragrant resinous juice. To the sub-order belong Myrrh (q.v.), Frankincense (q.v.), &c.

An'a, a termination added to proper names to designate collections of sayings, 'table-talk,' anecdotes, items of gossip, as *Johnsoniana*, *Boswelliana*; as well as notes about some person, or publications bearing upon him, as *Shakespeareana*, *Burnsiana*. Such titles were first used in France, where they became common after the publication of *Scaligerana* by the brothers Dupuy (1666). In English literature there are many works of this kind, from *Baconiana* (1679) to *Dickensiana* (1886). America, also, has its *Washingtoniana* (1800). A tolerably complete catalogue of such works up to its own date may be found in Namur's *Bibliographie des Ouvrages publiés sous le Nom d'Ana* (Brussels, 1839).

Anabaptists, a term often applied to those Christians who reject infant baptism and administer the rite only to adults; so that when a new member joins them, he or she, if baptised in infancy, is baptised a second time. The name (from Gr., 'to baptise again') is thus due to an accidental circumstance, and is disclaimed by the more recent opponents of infant baptism both on the Continent

and in Great Britain. It is properly applied to a set of fanatical enthusiasts called the Prophets of Zwickau, in Saxony, at whose head were Thomas Munzer (1520) and others, who appeared shortly after the beginning of the Reformation. Munzer went to Waldshut, on the borders of Switzerland, which soon became a chief seat of anabaptism, and a centre whence visionaries and fanatics spread over Switzerland. They pretended to new revelations, dreamed of the establishment of the kingdom of heaven on earth, and summoned princes to join them, on pain of losing their temporal power. They rejected infant baptism, and taught that those who joined them must be baptised anew with the baptism of the Spirit; they also proclaimed the community of goods and the equality of all Christians. These doctrines naturally fell in with and supported the 'Peasant War' (q.v.) that had about that time (1525) broken out. The sect spread rapidly through Westphalia, Holstein, and the Netherlands, in spite of the severest persecutions. At the battle of Frankenhausen the princes of Saxony, Hesse, and Brunswick crushed its progress in Saxony and Franconia. Still, scattered adherents of the doctrines continued. Melchior Hoffman, a furrier of Swabia, who appeared as a visionary preacher in Emden in 1528, installed a baker, John Matthiesen, of Haarlem, as bishop. Matthiesen began to send out apostles of the new doctrine. Two of these went to Munster, where they found fanatical coadjutors in the Protestant minister Rothmann, Knipperdolling, Bockhold, and others. With their adherents, they soon made themselves masters of the city; Matthiesen set up as a prophet, and, encouraged by a previous success, lost his life in a mad sally, with only thirty followers, against Count Waldeck, the prince-bishop of Munster, who was besieging the town. The churches were now destroyed, and twelve judges were appointed over the tribes, as among the Israelites; and Bockhold (1534) had himself crowned king of the 'New Zion,' under the name of John of Leyden. The anabaptist madness in Munster now went beyond all bounds. The city became the scene of the wildest licentiousness; until several Protestant princes, uniting with the bishop, took the city, and by executing the leaders after the cruellest tortures, put an end to the new kingdom (1535).

But the principles disseminated by the Anabaptists were not so easily crushed. Adherents of the sect had been driven to the Netherlands; and in Amsterdam the doctrine took root and spread. Bockhold also had sent out apostles, some of whom had given up the wild fanaticism of their master; abandoning the community of goods and women, they taught the other doctrines of the Anabaptists, and the establishment of a new kingdom of pure Christians. They grounded their doctrines chiefly on the Apocalypse. One of the most distinguished of this class was David Joris, a glass-painter of Delft (1601-56), who devoted himself to mystic theology, and sought to effect a union of parties. He acquired many adherents, who studied his Book of Miracles (*Wunderbuch*), which appeared at Deventer in 1542, and looked upon him as a sort of new Messiah. Being persecuted, he withdrew from his party, lived inoffensively at Basel, under the name of John of Bruges, and died there in the communion of the reformed church.

The rude and fanatical period of the history of anabaptism closes with the scandal of Munster. A new era begins with Menno Simons (see MENNONITES), who collected many of the scattered adherents of the sect, and founded congregations in the Netherlands and in Germany. His followers, however, expressly repudiated the distinctive doctrines of the Munster fanatics; and so little had their

sober and moderate life in common with the excesses of the latter, that the application of the term Anabaptists to them is unjustifiable. As a matter of fact, the German Anabaptists have left no representatives; and those bodies in England and America who resemble them only in practising adult baptism are discussed at BAPTISTS. See Belfort Bax's *Rise and Fall of the Anabaptists* (1903).

Anabasidae. See CLIMBING PERCH.

Ana'basis (Gr., literally, 'an ascent' or 'a march out of a lower into a higher country'), the name of two historical works: (1) *The Anabasis of Cyrus*, written by Xenophon, which gives a narrative of the unfortunate expedition of the younger Cyrus against his brother, the Persian king Artaxerxes, and of the retreat of his 10,000 Greek allies under the command of Xenophon, after the battle of Cunaxa (401 B.C.). (2) *The Anabasis of Alexander*, written by Arrian, and giving an account of the campaigns of Alexander the Great.

Anableps (Gr. *anablepsis*, 'looking up'), a genus in Agassiz's cyprinodont family of bony fishes with open air-bladders. They are especially noteworthy for their projecting eyes, which are divided into an upper and lower portion. The outer covering or cornea is crossed by a dark band, and the inner iris

Anableps tetrophthalmus.

is similarly divided, so that there are really two pupils instead of one. This unique structure is supposed to be associated with a habit which these fishes are said to have of swimming with the eyes partly out of the water. *A. tetrophthalmus* inhabits the rivers of Guiana and Surinam.

Anabolism, a general name for the constructive chemical processes which go on in the living body, in contrast to the opposite, but simultaneously proceeding, disruptive processes summed up in the term Katabolism. In other words, vital metabolism has two phases—the one tending to up-building, construction, assimilation; the other tending to down-breaking, disruption, disassimilation. See METABOLISM, PHYSIOLOGY, PROTOPLASM.

Anacardiaceæ. See TEREBINTH; also CASHEW NUT, PISTACIA, MANGO, SUMACH.

Ana'charis, a genus of plants of the natural order Hydrocharideæ, of which a species, *Ana'charis alsinastrium* (*Elodea canadensis*), has become naturalised in Britain. It is a native of North America, growing in ponds and slow streams; and is a dark-green, much-branched perennial, entirely floating under water. The plant was first found in Britain in 1842, by Dr Johnston, in the lake of Duns Castle; and again in 1847 in Leicestershire. The male flowers, rare as compared with the female flowers even in America, were unknown in Britain till seen by the late Mr David Douglas in a pond on the Braid Hills near Edinburgh, in August 1880 (see *Science Gossip*, Nov. 1880). The plant is now very abundant and troublesome in the Trent, Derwent, and other rivers; in fact, much more so than in America. Its rapidity of growth is extraordinary. Immense masses disfigure the shallows of the Trent, and cover the

beds of the deeps. It strikes its shoots under the mud in a lateral direction for six inches or a foot, and then rises and spreads. The stems are very brittle, and every fragment is capable of growing,

Anacharis alsinastrum.

so that the means usually adopted to get rid of it serve also for its propagation. It appears that water-fowl are very fond of it; and by them, probably, it is easily conveyed from one pond or river to another. It has been found that swans may be fed upon it with advantage, and its excessive growth kept down more effectually in this way than in any other. It seems to be an impediment to the progress of salmon ascending the rivers in which it occurs; but for some kinds of fish it probably affords both food and shelter. The manner of its introduc-

tion into Britain is unknown, although it has been conjectured that it may have escaped from some garden-pond—a conjecture the more doubtful, from the distance between the localities in which it was first found; but its rapid increase is of great scientific interest, in connection with the important subject of the distribution of species. As being over-abundant in canals and water-courses, the plant involves some serious economic considerations. It is remarkable that in North America, its native land, it never grows so as to block the rivers. The plant is also of interest to vegetable physiologists, since exhibiting peculiarly well, under moderate power of the microscope, the phenomenon of circulation of the protoplasm within the cells.

Anachar'sis, a Scythian prince who travelled widely in quest of knowledge, and visited Athens in the time of Solon. He was received with great respect for his remarkable wisdom, and was admitted to the Athenian franchise. The letters which bear his name were written long after his time. It is said that, after his return to his native land, he was put to death by order of the king, who feared the introduction of the Greek mysteries, in which it was supposed that Anacharsis had been initiated. J. J. Barthélemy (q.v.) borrowed his name for that of the hero of his *Voyage du Jeune Anacharsis en Grèce* (1788).

Ana'chronism (Gr. *ana*, 'backwards,' *chronos*, 'time'), the erroneous reference of a circumstance widely in quest of knowledge, and visited Athens in the time of Solon. He was received with great respect for his remarkable wisdom, and was admitted to the Athenian franchise. The letters which bear his name were written long after his time. It is said that, after his return to his native land, he was put to death by order of the king, who feared the introduction of the Greek mysteries, in which it was supposed that Anacharsis had been initiated. J. J. Barthélemy (q.v.) borrowed his name for that of the hero of his *Voyage du Jeune Anacharsis en Grèce* (1788).

figures than nineteenth-century men and women in antique garb. There is hardly a novel of its class that contains more study than Thackeray's *Esmond*, yet here a Jacobite whistles 'Lilliburlero,' and a book is spoken of in 1712 which was not published until 1750. Sometimes an anachronism is purposely made for the sake of effect, or to bring certain events within convenient compass for dramatic purposes. Thus, Shakespeare makes Cassius say, in *Julius Caesar*, 'The clock hath stricken three;' and Schiller, in his *Piccolomini*, introduces a lightning-conductor more than a hundred years before the date of its invention. These discrepancies, however, do not seriously injure the general truth of a poetical work. The anachronism is more offensive when, in a work which pedantically adheres to the costumes and other external features of old times, we find a modern style of thought and language, as in the old French dramas of Corneille and Racine. In popular epic poetry it is a common feature. Achilles is always young; Helena, always beautiful. In their versions of old classic traditions, the writers of the middle ages converted Alexander, Æneas, and other ancient heroes, into good Christian knights of the 12th century. In the *Nibelungen-lied*, Attila and Theodoric are good friends and allies, though the latter began to reign some forty years after the former. At the end of the poem, the heroine, who must have been nearly sixty years old, is still 'the beautiful Queen Kriemhild.'

Anacolu'thon is a term employed both in Grammar and Rhetoric, to denote the absence of strict logical sequence in the grammatical construction. Good writers sometimes sacrifice the logical sequence to emphasis, clearness, or graceful arrangement. An example is Coleridge's 'His young and open soul—dissimulation is foreign to its habits.' In colloquial speech, nothing is more common than examples of anacoluthon.

Anaconda (*Eunectes murinus*), a large South American water-snake of the Python family, closely related to the boa-constrictor. The upper part of the front of the head is armed with shield-like plates, replaced by scales farther back. The minute vertical nostrils at the end of the snout can be entirely closed, a fact in association with the aquatic habit of the animal. In size it is hardly exceeded, unless by the pythons, as some specimens have measured from 25 to 30 feet in length. The general colour of the adult is blackish green, with rows of spots along the back and sides. Traces of the hind-legs can be detected. The anaconda is ovoviviparous. It is found in the rivers of Guiana and Brazil, swimming like an eel, or floating with the stream, or lying in wait by the bank for the agoutis, pacas, capybaras, ant-eaters, iguanas, &c. on which it feeds. It is comparatively helpless on land, and is then often killed. The skin is used for making boots and bags, the fat is also utilised, and the flesh is sometimes eaten. See BOA CONSTRICTOR, and PYTHON.

Ana'creon, one of the most esteemed lyric poets of Greece, was born about 550 B.C. at Teos, an Ionian city in Asia Minor. With his fellow-townsmen he emigrated to Abdera, in Thrace, on the approach of the Persians. Thence he was invited to the court of Polycrates, the ruler of Samos; and here he sang, in light and flowing strains, the praise of wine and beauty. After the death of Polycrates, he went to Athens, and was received with distinguished honour by Hipparchus. We know nothing certain of his life after the fall of Hipparchus, but that he left Athens; and tradition tells that he died at the age of 85, by being choked by a dried grape.

Great honours were paid to him after his death; Teos put his likeness upon its coins, and a statue was raised to him on the Acropolis of Athens, which represented him in a state of vinous hilarity.

Of his poems, only a few genuine fragments have been preserved, for the *Odes* attributed to him are now admitted to be spurious. Of these there are about sixty, devoted to love and wine, marked by great simplicity and delicacy of expression, fertility of invention, and variety of illustration. Moore found a congenial task in translating them into English verse. The genuine fragments appear in Bergk's *Poetæ Lyrici Græci* (5th ed. vol. iii. 1900).

Anacyclus. See PELLITORY OF SPAIN.

Anadyom'eué ('emerging'), a name given to Aphrodite from her being born of the sea-foam. Apelles gave the name its celebrity from his masterpiece, a painting of the goddess in the moment of rising from the sea, wringing her flowing wet hair. Phryne was supposed to have supplied the model. The Coans placed the picture in the temple of Asklepios. Augustus afterwards placed it in the temple of Venus as the ancestress of the Julian house.

Anadyr, or ANADIR, a sea or gulf of North-east Siberia, and a resort of whalers. The Anadyr River flows into the Gulf of Anadyr, after a course of about 500 miles from the Stanovoi Mountains, through a rocky and barren country.

Anæmia (Gr., 'bloodlessness') denotes a condition in which the blood is deficient either in quantity or quality for the adequate performance of its functions. The total quantity of blood in the body may be diminished. More commonly there is no alteration in the total quantity, but the number of red corpuscles is reduced below the normal 5,000,000 per cubic millimetre. Again, while there may be little or no diminution in their number, the corpuscles may be small and poorly endowed with their most important constituent, hæmoglobin, which acts as the carrier of oxygen from the lungs to the tissues. Deficiency of hæmoglobin is the essential feature in all forms of anæmia.

The symptoms due to anæmia *per se* are weakness and languor; breathlessness, palpitation, and faintness; headache, sleeplessness, and irritability; digestive troubles and, in women, menstrual disturbance. The patient usually looks pale, but in persons who have been exposed to the weather this may not be conspicuous, and the pallor must be sought in the lips, gums, and the inner surface of the eyelids. In cases where the anæmia is not associated with severe illness the patient usually remains or becomes plump, partly because the tissues are not so readily oxidised, and partly because of the patient's lethargy.

Pernicious anæmia occurs most commonly between the ages of thirty and fifty, though no age is exempt. In this country, at least, it is more common in males. It may follow depressing conditions of any kind, but in many instances no such history can be obtained. In typical cases, besides the signs common to all anæmias, there is a lemon-yellow pallor of the skin, a tendency to febrile attacks, and gastro-intestinal disturbance. The blood shows a remarkable reversion to the type found in the early embryo. The number of red corpuscles may fall to a lower figure than is reached in any other condition. The hæmoglobin is necessarily diminished also, but the average size of the corpuscles is greater than normal, so that the hæmoglobin value of each corpuscle is increased. Such blood is said to show a high colour index. The disease is due to some unknown toxic agency affecting not only the blood but its source,

the red bone marrow. The condition is a serious one. Acute cases may die within a month of onset, but chronic cases may live for more than ten years. There is an extraordinary tendency to remission and relapse. Arsenic seems to exert a favourable influence on the course of the disease.

Chlorosis is the subject of a separate article.

Secondary or symptomatic anæmia may arise from a very large number of causes. The most obvious is hæmorrhage, either from a wound, a ruptured vessel, or ulcerated surface, from various parts of the body in the bleeding diseases, from the respiratory, urinary, or genital passages. The suddenness of onset in many of these conditions may add to the severity of symptoms. Blood may be lost so quickly that the heart cannot readily accommodate its work to the diminished quantity of fluid, and circulatory embarrassment and faintness may result. Few conditions give rise to such acute mental anxiety as hæmorrhage. Other causes of secondary anæmia are blood destruction, from the action of such agencies as the malarial parasite; poisons which shorten the life of the corpuscles or diminish the activity of the bone-marrow—e.g. fevers, sepsis, cancer, and syphilis; improper nourishment and unfavourable surroundings; exhausting conditions, such as chronic catarrh, Bright's disease, and prolonged lactation. The symptoms are often largely masked by those of the causal condition which may also obscure the blood picture. In most cases there is pallor without the yellow tint of pernicious anæmia or the green complexion of chlorosis. The colour index may be low, but seldom shows much departure from unity; i.e. corpuscles and hæmoglobin are reduced proportionately. The course and treatment vary with the cause.

Other varieties of anæmia, such as *splenic anæmia* and *aplastic anæmia*, are exceedingly rare. Certain diseases of the bone-marrow, such as leucocythæmia, in which there is a great increase in the number of white cells in the blood, were formerly classified with the anæmias. Such conditions may be important causes of anæmia, but are no longer included among its manifestations.

For mine's anæmia, see ANKYLOSTOMIASIS.

Anæsthesia (Gr., 'lack of sensation') is a term used to express a loss of sensibility to external impressions, which may involve a part or the whole surface of the body. It may occur naturally as the result of disease, or may be produced artificially by the administration of *anæsthetics*. In some diseased conditions of the nervous centres, a part of the body may become totally insensible to pain, while in another part sensation may be unnaturally acute, constituting a state of hyperæsthesia. When a nerve is divided, there is no feeling of touch or pain referred to the parts which it supplies, because these are cut off from communication with the brain; and in some diseases, as European leprosy, a loss of sensation in patches of the skin is an early and characteristic symptom. Insensibility to external impressions may be either *general*—i.e. affecting the whole body, or *local*, where only that part is affected to which the anæsthetic agent is applied.

In ancient writers, we read of insensibility or indifference to pain being obtained by means of Indian hemp (*Cannabis indica*), either smoked or taken into the stomach. The Chinese, more than 1500 years ago, used a preparation of hemp, or *ma-yo*, to annul pain. The Greeks and Romans used mandragora for a similar purpose (*poiein anaisthesian*); and as late as the 13th century, the vapour from a sponge filled with mandragora, opium, and other sedatives was used. The mandragora, however, occasionally induced convulsions, with other alarming symptoms; and though

Bullein, an English physician (died 1579), mentions the possibility of putting patients who were to be operated upon into 'a trance or a deepe terrible dreame' by its use, it gradually became obsolete, and was banished from the pharmacopœia. John Baptista Porta, of Naples, in his work on Natural Magic (1597), speaks of a quintessence extracted from medicines by somniferous *menstrua*. This was kept in leaden vessels, hermetically closed, lest the *aura* should escape. 'When it is used, the cover being removed, it is applied to the nostrils of the sleeper, who draws in the most subtle power of the vapour by smelling, and so blocks up the fortress of the senses, that he is plunged into the most profound sleep, and cannot be roused without the greatest effort. . . . These things are plain to the skilful physician, but unintelligible to the wicked.' In 1784, Dr Moore, of London, used compression on the nerves of a limb requiring amputation, but this method was in itself productive of much pain. In 1800, Sir Humphry Davy, experimenting with the nitrous oxide or *laughing-gas*, suggested its usefulness as an anæsthetic; and in 1828, Dr Hickman suggested carbonic acid gas.

As early as 1795, Dr Pearson had used the vapour of sulphuric ether for the relief of spasmodic affections of the respiration. The fact that sulphuric ether could produce insensibility was shown by the American physicians, Godwin (1822), Mitchell (1832), Jackson (1833), Wood and Bache (1834); but it was first used to prevent the pain of an operation in 1846, by Dr Morton, a dentist of Boston. The news of his success reached England on 17th December 1846; on the 22d, Mr Robinson, a dentist, and Mr Liston, the eminent surgeon, operated on patients rendered insensible by the inhalation of sulphuric ether. This material was extensively used for a year, when Sir J. Y. Simpson, of Edinburgh, discovered the anæsthetic value of Chloroform (q.v.) when inhaled, and introduced the use of it into his department, midwifery. Since that time chloroform has been the anæsthetic in general use in Europe, but ether is preferred in America. It is now the opinion of most medical men that chloroform should not be given where there is weak action of the heart from disease. Other substances have been used by inhalation, such as nitrous oxide gas, which is the best and safest anæsthetic for operations that last only one or two minutes, as in the extraction of teeth. At present the safer combination is alcohol 1, chloroform 2, ether 3 parts, known as 'A.C.E.' or '1.2.3.'

The employment of general anæsthetics in surgery has greatly increased the scope of the surgeon's usefulness, and has been a great boon to suffering humanity. It is, however, fraught with a certain amount of danger. However much care may be taken in administration, an occasional fatal accident occurs from the action of the anæsthetics employed. In these cases there is generally disease of the heart, or a hypersensitive nervous system, predisposing to sudden sinking, or to shock, or preceding bronchitis or kidney trouble.

Local anæsthesia, artificially produced, is of great value in minor operations, and in painful affections of limited areas of the body. It depends upon a paralysis of the sensory nerves of the part, and may be induced by the application of *cold*, or of medicinal agents. An ether spray thrown on the part, produces such intense cold by its evaporation, that the part is completely numbed, and a layer of ice forms on its surface. The after effects, however, when reaction sets in, are very painful, and there is danger that in weak constitutions sloughing and ulceration may follow. Of medicinal agents, the best is *cocaine*, prepared from the coca shrub of Peru (*Erythroxylon coca*). In the

form of a five to ten per cent. watery solution, this drug is introduced into the tissues by a hypodermic needle, and produces complete anæsthesia of the part thus treated in from three to fifteen minutes. Rarely it produces giddiness, but has no unpleasant local after effects. Thymol, menthol, aconite, belladonna, chloroform (the last three as the well-known A B C liniment), phenol, chloral, and Indian hemp, have also a local anæsthetic action if rubbed on the skin, or applied to abraded surfaces.

Anagallis. See PIMPERNEL.

Anagni, a town of Italy, on a hill, 40 miles ESE. of Rome. The seat of a bishop since 487, it has an old, but much modernised cathedral, and was the birthplace of four popes—Innocent III., Gregory IX., Alexander IV., and Boniface VIII. The chief city of the *Heinici*, it was a place of importance during the whole period of Roman history, and Virgil mentions it as 'wealthy Anagnia.' Pop. 10,500.

Anagram (Gr. *ana*, 'up,' and *gramma*, 'a letter of the alphabet'), the transposition of the letters of a word, phrase, or short sentence, so as to form a new word or sentence. It originally signified a simple reversal of the order of letters, but has long borne the sense in which it is now used. The Cabalists attached great importance to anagrams, believing in some relation of them to the character or destiny of the persons from whose names they were formed. Plato entertained a similar notion, and the later Platonists rivalled the Cabalists in ascribing to them mysterious virtues. Although now classed among follies, or at best among ingenious trifles, anagrams formerly employed the most serious minds, and some of the Puritan writers commended the use of them. Cotton Mather, in his elegy on the death of John Wilson, the first pastor of Boston, in New England, mentions

His care to guide his flock and feed his lambs

By words, works, prayers, psalms, alms, and anagrams.

The best anagrams are such as have, in the new order of letters, some signification appropriate to that from which they are formed. It was a great triumph of the medieval anagrammatist to find in Pilate's question, '*Quid est veritas?*' (What is truth?) its own answer: '*Est vir qui adest*' (It is the man who is here). With equal appropriateness, Horatio Nelson may read '*Honor est a Nilo*' (Honour is from the Nile), and Florence Nightingale, 'Flit on, cheering angel.' Anagrams, in the days of their popularity, were much employed, both for complimentary and for satirical purposes; and no little straining was often employed in the omission, addition, or alteration of letters, although, of course, the merit of an anagram depended much upon its accuracy. An interesting survival of anagram-making was seen in the absurd word-competitions for large money prizes, offered about the time of Queen Victoria's jubilee (1887), ostensibly to celebrate the occasion.

Marie Touchet, the name of a favourite mistress of Charles IX. of France, was read '*Le charme tout*' (I charm every one); the flatterers of James I. of England found in his name, James Stuart, 'a just master,' and proved his right to the British monarchy, as the descendant of the mythical King Arthur, from his name Charles James Stuart, which becomes 'Claims Arthur's Seat.' But perhaps the happiest of anagrams was that which failed to restore the sanity of Lady Eleanor Davies, the wife of Sir John Davies the poet. The poor lady was half-crazy, and she began to fancy herself a prophetess, because she discovered that from the letters of her own name could be read 'Reveal, O Daniel.' Political prophecy was a dangerous

game under Charles I., and at last she found herself arraigned before the Court of High Commission. Judge and bishop reasoned with her in vain, until the Dean of Arches laughed her out of court by finding also in her name, Dame Eleanor Davies, the unfortunate words, 'Never so mad a Ladie.'

Many of the pseudonyms adopted by authors have been merely transposed forms of their own names; thus Calvinus becomes 'Alcuinus'; François Rabelais, 'Alcofribas Nasier'; Bryan Waller Proctor, 'Barry Cornwall, poet.' The most famous name of this class, that of 'Voltaire,' was formed from 'Arouet, l. j.'—i.e. 'Arouet the younger.' See Wheatley, *On Anagrams* (1862).

Anahuac (a term signifying, in the old Mexican language, 'near the water'), the original name of the ancient kingdom of Mexico. It is now used to designate either the whole of the tableland of Mexico or certain portions thereof, more or less extensive, with the capital as a common centre. This plateau has a height of from 6000 to 8000 feet above the sea, and is generally level, though the great volcanoes of Jorullo and Popocatepetl rise out of it. The plateau, which comprises three-fifths of the republic of Mexico, is bounded east and west by the two great chains of the Cordilleras. The Anahuacans are the Aztecs. See MEXICO.

An'akim, a people living in the south of Palestine, and especially about Hebron, then called Kirjath-arba. They are described in Scripture as a race of giants, and their name may come from a Hebrew root meaning strength or stature. They are also called 'Sons of Anak,' and were dispossessed by Joshua. See Num. xiii.

Analcite, or ANALCIME, a zeolite of composition $\text{Na}_2\text{Al}_2\text{Si}_2\text{O}_{10} \cdot 2\text{H}_2\text{O}$, found in pink or white pseudocubic crystals.

Anal Glands, pouches from the end of the intestine beside the anus. They occur especially in mammals, but also in snakes, lizards, and other reptiles, and in some invertebrates, such as insects, and consist of cells which exhibit a special development of the general glandular properties so abundantly associated with the skin. It is impossible to draw any hard and fast line between true anal glands and the numerous glandular pouches occurring in various parts of the body—e.g. head, back, groin, limbs, and external generative organs. The secretion of the glandular cells has usually a strong smell, and a fatty or oily composition. They are sometimes of protective advantage, and in other cases doubtless auxiliary to sexual attraction. See GLANDS, SKIN, MUSK GLANDS, BEAVER, CIVET, SKUNK.

An'alogue, a technical term in Biology, used to denote physiological, independent of morphological resemblance. Organs are *analogous* to one another, or are *analogues*, when they perform the same function, though they may be altogether different in structure; as the wings of a bird, and the wings of an insect. Organs, again, are *homologous*, or *homologues*, when they are constructed on the same plan, undergo a similar development, and bear the same relative position, and this independent of either form or function. Thus, the arms of a man and the wings of a bird are homologues of one another, while the wing of a bird and the wing of a bat are both analogous and homologous. See DARWINIAN THEORY, MORPHOLOGY.

Anal'ogy, a term, originally Greek, which signifies an agreement or correspondence in certain respects between things in other respects different. It makes a resemblance of relations, as in the phrase, 'Knowledge is to the mind what light is to the eye.' Euclid employed it to signify proportion, or the equality of ratios, and it has retained this

sense in mathematics; but it is a term little used in the exact sciences, and of very frequent use in every other department of knowledge and of human affairs. In Grammar, we speak of the analogy of language—i.e. the correspondence of a word or phrase with the genius of the language, as learned from the manner in which its words and phrases are ordinarily formed. Analogy, in fact, supposes a rule inferred from observation of instances, and upon the application of which, in other instances not precisely, but in some respects, similar, we venture, with more or less confidence, according to the degree of ascertained similarity, and according to the extent of observation from which our knowledge of the rule has been derived. The opposite to analogy is *anomaly* (Gr., 'irregularity'); and this term is used not only in grammar, but with reference to objects of natural history which in any respect are exceptions to the ordinary rule of their class or kind. Here it strictly means the resemblance of function between organs which are essentially different (see ANALOGUE above).

In the progress of science, analogies have been discovered pervading all nature, and upon which conclusions are often based with great confidence and safety. It is a kind of presumptive reasoning from parallel cases that indeed warrants only probable conclusions; but the probability may become of a very high degree, and in the affairs of life we must often act upon conclusions thus attained. Reasoning from analogy, however, requires much caution in the reasoner. Yet even when its conclusions are very uncertain, they often serve to guide inquiry and lead to discovery. Many of the most brilliant discoveries recently made in natural science were the result of investigations thus directed. Where the proper evidence of truth is of another kind, arguments from analogy are often of great use for the removal of objections. It is thus that they are employed by Bishop Butler in his *Analogy of Religion, Natural and Revealed, to the Constitution and Course of Nature*. In law, reasoning from analogy must often, to a certain extent, be admitted in the application of statutes to particular cases. Upon similar reasoning the practice of medicine very much depends. To discover the meaning of any literary work, it is also often necessary; the sense of the author in a passage somewhat obscure being in some measure determined according to passages in which he has expressed himself more clearly. The application of this rule to the interpretation of Scripture is a point of difference between Protestants and Roman Catholics, the latter insisting upon the interpretation of difficult passages solely by ecclesiastical tradition and authority, while the former claim the right to apply analogy of interpretation. The inspiration of Scripture, however, when fully admitted, warrants a more confident use of analogical reasoning than in the case of the works of an uninspired author.

Anal'ysis (Gr., 'taking apart') and its converse *Synthesis* ('putting together') are now generally used to designate two complementary processes, the correlatives of each other, employed in chemistry, logic, mathematics, and philosophy. Analysis is the resolution of a whole into its component parts, the tracing of things to their source, and so discovering the general principles underlying individual phenomena; Synthesis is the explanation of certain phenomena by means of principles which are for this purpose assumed as established. Analysis, as the resolution of our experience into its original elements, is an artificial separation; while synthesis is an artificial reconstruction. We speak of an *analytic* method in science, and of a *synthetic* method; and both are necessary, the one coming to

the assistance of the other to secure against error, and promote the ascertainment of truth. The analytic method proceeds from the examination of facts to the determination of principles, from the individual to the universal; whilst the synthetic method proceeds to the determination of consequences from principles known or assumed, to the individual from the universal. It will thus be seen that they are really two necessary parts of the same method, and that, whereas the value of the synthesis depends on the accuracy of the analysis which has established the principle from which the synthesis sets out, so, on the other hand, an analysis which does not aspire to a synthesis, halts on the way. Synthesis without analysis gives a false science, since it is a pure imagination, based simply on hypothesis; and analysis without synthesis gives an incomplete science. The ideal of science and of philosophy can only be attained by a method which combines the two processes, and the test of the perfection of a theory is the harmony of the results obtained by them.

The part of Herbert Spencer's *Psychology* which he calls Special Analysis (following the preliminary General Analysis), has 'for its aim, to resolve each species of cognition into its components. Commencing with the most involved ones, it seeks by successive decompositions to reduce cognitions of every order to those of the simplest kind; and so, finally, to make apparent the common nature of all thought, and disclose its ultimate constituents;' while the synthesis describes the nature and genesis of the different modes of intelligence. In *Logic*, analysis is the division of a concept into the qualities or attributes of which it is constituted (see ABSTRACTION), whilst synthesis is the reverse process of adding together the qualities or attributes which determine a particular concrete. See GENERALISATION, INDUCTION, LOGIC, ALGEBRA, GEOMETRY.

In *Grammar*, analysis is a term much used since 1852 for the school exercise of distinguishing the different elements composing a sentence, or any part of it. It is allied to logical analysis, being a systematic resolution of the sentence into elements, performing different functions in the expression of thought, with definite relations to the whole sentence and to each other, as *subject* and *predicate*, with their respective *enlargements*. Dr Morell was one of the first of English grammarians to make a systematic use of this method in books for teaching.

Mathematical Analysis, in the modern sense of the term, is the method of treating all quantities as unknown numbers, and representing them for this purpose by symbols, such as letters, the relations subsisting among them being thus stated and subjected to further investigation. It is therefore the same thing with algebra in the widest sense of that term, although the term algebra is more strictly limited to what relates to equations, and thus denotes only the first part of analysis. The second part of it, or analysis more strictly so called, is divided into the Analysis of Finite Quantities, and the Analysis of Infinite Quantities. To the former, also called the Theory of Functions, belong the subjects of Series, Logarithms, Curves, &c. The Analysis of Infinites comprehends the Differential Calculus, the Integral Calculus, and the Calculus of Variations (see the several articles). To the diligent prosecution of mathematical analysis by minds of the greatest acuteness, is to be ascribed the great progress both of pure and applied mathematics within the last two centuries.

The analysis of the ancient mathematicians was a thing entirely different from this, and consisted simply in the application of the analytic method as opposed to the synthetic, to the solution of geometrical questions. That which was to be proved

being in the first place assumed, an inquiry was instituted into those things upon which it depended, and thus the investigation proceeded, as it were, back, until something was reached which was already ascertained, and from which the new proposition might be seen by necessary consequence to flow. A reversal of the steps of the inquiry now gave the synthetical proof of the proposition. The modern mathematical analysis affords a much more easy and rapid means of solving geometrical questions; but the ancient analysis also afforded opportunity for the exercise of much acuteness, and was the chief instrument of the advancement of mathematical science until comparatively recent times. The invention of it is ascribed to Plato; but of the works of the ancients on geometrical analysis none are extant, except some portions of those of Euclid, Apollonius of Perga, and Archimedes.

Analysis, in Chemistry, is the term applied to that department of experimental science which has for its object the chemical disunion or separation of the constituents of a compound substance: thus, the resolution of water into its components hydrogen and oxygen; of common salt into chlorine and sodium; of marble into lime and carbonic acid; of rust into iron and oxygen; of sugar into carbon, hydrogen, and oxygen; and of chloroform into carbon, hydrogen, and chlorine—are all examples of chemical analysis. This department of chemistry, therefore, takes cognisance of the breaking down of the more complex or compound substances into their more simple and elementary constituents, and is antagonistic to *chemical synthesis*, which treats of the union of the more simple or elementary bodies to produce the more complex or compound. Chemical analysis is of two kinds: *Qualitative* analysis, which determines the quality or nature of the ingredients of a compound, without regard to the quantity of each which may be present; and *quantitative* analysis, which calls in the aid of the balance or measure, and estimates the exact proportion, by weight or volume, in which the several constituents are united. Thus, *qualitative* analysis informs us what water, marble, common salt, &c. are composed of; but it remains for *quantitative* analysis to tell us that water consists of 1 part of hydrogen by weight united with 8 parts of oxygen; that marble is composed of 56 parts of lime, and 44 of carbonic acid; common salt, of 35½ parts of chlorine, and 23 of sodium; turpentine, of 30 carbon, and 4 hydrogen; chloroform, of 12 carbon, 1 hydrogen, and 106½ chlorine.

The divisions of inorganic (mineral) chemistry and organic (vegetable and animal) chemistry have led to a corresponding classification of chemical analysis into *inorganic* analysis, comprehending the processes followed and the results obtained in the investigation of the atmosphere, water, soils, and rocks; and *organic* analysis, treating of the modes of isolation, and the nature, of the ingredients found in or derived from organised structures—viz. plants and animals. Both departments afford examples of what are called *proximate* and *ultimate* analysis. Proximate analysis is the resolution of a compound substance into components which are themselves compound: thus, in inorganic chemistry, marble is resolved into lime (calcium united with oxygen) and carbonic acid (carbon with oxygen); whilst ultimate analysis comprehends the disunion of a compound into its *elements* or the simplest forms of matter: thus, lime into calcium and oxygen; carbonic acid into carbon and oxygen; water into hydrogen and oxygen. Organic chemistry affords still better examples of each class: thus, ordinary wheat-flour, when subjected to proximate analysis, yields, as its proximate components, gluten (vegetable fibrin), albumen, starch, sugar, gum, oil, and saline matter;

but each of these proximate ingredients is in itself compound, and when they undergo ultimate analysis, the gluten and albumen yield, as their ultimate elements or constituents, carbon, hydrogen, oxygen, nitrogen, sulphur, and phosphorus; and the starch, sugar, gum, and oil are found built up of carbon, hydrogen, and oxygen.

Several other terms are in use in chemical treatises: thus, *Gas analysis* is applied to the processes employed in the examination of the various gases, and is every day becoming of more and more importance and interest. *Metallurgical analysis* includes the smelting of metallic ores, the assay of alloys of gold, silver, &c., and, in general, everything that pertains to the ultimate analysis of metallic ores and compounds. *Agricultural analysis* is restricted to the examination of manures, feeding-stuffs, and soils; *Medical or Physiological analysis*, to the investigation of blood, urine, and other animal fluids and juices, and the examination of medicinal compounds; whilst *Commercial analysis* is the term used where great accuracy or nicety of detail is not required in an analysis, but where the commercially important constituents alone are determined, as the separation and recording of the amount of phosphates, ammonia, and alkaline salts in a sample of guano; the total amount of saline matter in a certain water; the iron in an ironstone, the lime in a limestone, &c.

Generally speaking, there are three methods in use in analysis. These are the *Volumetric*, *Gravimetric*, and *Spectroscopic*. The *Volumetric* method submits the sample to certain characteristic reactions, employing as reagents liquids of known strength, called standard solutions; and by means of colour tests determines when a certain reaction is complete (see ALKALIMETRY). From the data thus obtained, it is possible to calculate the weight of substance present in the sample under examination. The *Gravimetric*, on the other hand, seeks to precipitate the metal or other substance in a convenient form for weighing, and makes constant use of the Balance. The *Spectroscopic* method depends on the separation of the different rays of light by means of a spectroscope (see SPECTRUM). The substance under examination is usually volatilised in the flame of a Bunsen burner; and when the spectroscope is applied, coloured lines, varying with different substances, are seen across the spectrum, and enable the analyst to detect the most minute proportions with certainty.

COMMERCIAL or PHARMACEUTICAL ANALYSIS differs from inorganic or organic analysis, pure and simple, in dealing usually with complex mixtures, to which it is impossible to apply tests having a definite value as to the information they afford. Thus, a mixture of various inorganic salts can be analysed with certainty by proceeding on well-known rules; but, as yet, no one can be confident in the analysis of an unknown mixture containing, perchance, sirups or tinctures, along with infusions of animal or vegetable origin. To such a mixture it is necessary to apply many physical processes, in the hope that these will so separate the constituents as to render it possible to recognise them either by appearance, odour, or specific test. Thus it comes about that a knowledge of experimental physics, no less than of chemistry, is essential to the successful analyst. In the following paragraphs it is proposed to indicate the physical processes which let the most light into the darkness of an unknown commercial mixture, but for details the reader must consult a practical treatise.

Distillation.—The mixture being placed in a glass flask furnished with a thermometer, heat is applied, and the boiling-point noted. If this gradually rises, it indicates that the mixture contains more than one volatile liquid; and by

separating the various portions of distillate, according to the temperature at which they pass over, it is often possible to obtain the samples sufficiently pure to be recognised. The term *fractionation* or *fractional distillation* is applied to this method. If a non-volatile residue remains in the flask, it must be examined from other points of view. Thus, substances may be divided into: (1) Volatile—e.g. alcohol, ether, &c.; (2) Not volatile except along with other bodies—e.g. glycerine, which cannot be distilled alone, but passes over along with water vapour; (3) Non-volatile—e.g. fixed oils, olive, rape, &c.

Solution.—This may be applied in two ways. The solvent, be it alcohol, ether, water, or other liquid, is shaken with the substance under examination, and in many cases dissolves one ingredient, to the exclusion of others. Thus, it is desired to know how much oxide of iron is present in a sample of polishing-paste. Treatment with ether dissolves the fatty substances, and leaves the oxide free to be estimated in the usual manner. The other way consists in shaking ether or chloroform with the watery solution of the substance, when it will be found that some of the ingredients (more soluble in these liquids than in water) have been dissolved, and may be obtained on evaporation.

Rotation of the Polarised Ray.—It is found that many substances, and even the solutions of optically active compounds, have the power of rotating the plane of polarisation of a ray of light, and in many cases the extent of this rotation is sufficient to detect not only the presence but even the proportions of the substance to which it is due. Such bodies as sugar, turpentine, alkaloids, camphor, albumen, &c. exert this power.

Fluorescence (q.v.) is often of great assistance in commercial analysis. Thus, it is possible to pronounce the intense bitterness of a sirup to be due not to quinine, but to some other bitter, if no fluorescence is apparent; while the green fluorescence often noted on pens is a clear indication that the ink employed contains some colouring matter other than indigo, probably an aniline dye.

Melting and Solidifying Point.—The knowledge of this is of much importance, as, for example, in a case where common or other resins had been mixed with small pieces of amber. In such a case, the more fusible resin would melt and run away, leaving the bodies of higher melting-point. In other cases where no separation takes place, as with various kinds of wax, it enables the presence of paraffin or other foreign bodies to be detected. Adulteration of essential and fixed oils may frequently be exposed by this simple test.

Ignition on a piece of platinum or a porcelain dish is the simplest method of removing organic matter from inorganic, the latter usually remaining behind as a residue.

The specific gravity, the colour, odour, taste, crystalline form, solvent powers, and inflammability are all important factors in commercial analysis; while even such an apparently simple property as the size of drop which falls from a vessel containing the liquid, is in some cases the crucial test which decides as to the purity or otherwise.

The *spectroscope* is a powerful instrument, especially in pharmaceutical analysis. When a glass vessel, containing a tincture of a drug, is examined through the spectroscope, absorption spectra are seen (see SPECTRUM), and as these are characteristic of various herbs, they have been much used in recognising their presence in mixtures.

Sublimation.—When very carefully heated under a watch-glass, many alkaloids and other active principles yield sublimates having a characteristic crystalline form, which is easily recognised when examined under the microscope.

Microscopical Examination is a *sine qua non* when flour, or indeed any organic powder, is in question. Under the microscope, the different forms of starch are easily recognised, and by counting the granules of each variety in the visible field, one can arrive at the approximate proportions of each that are present.

Such, then, are some of the most valuable methods of commercial analysis; and in the examination of an unknown substance, many or all of them must be tried, the ingenuity of the chemist having here unbounded scope. For instance, supposing a mixture contained olive-oil, chloroform, glycerine, alcohol, and flour, the following course (capable of infinite variation) would soon lead to the detection of its ingredients. The microscope would at once pronounce as to the name of the starch, and after filtration through paper, the liquid being placed in a flask and heated, the chloroform and alcohol would pass over into the receiver. The residue of glycerine and olive-oil being non-miscible, could be readily separated into its two constituents, each of which could be recognised by specific gravity, taste, or solubility, as well as other more chemical tests. The chloroform and alcohol, on being poured into water, would at once separate into two layers, the lower of chloroform with a trace of alcohol, the upper of water and alcohol with a trace of chloroform. Numerous precautions are of course necessary to make sure that no substance remains undetected, and in many cases the chemist tries to re-combine his mixture from the separate pure ingredients, so as to give greater certainty to his conclusions. Such a method is called the *synthetic* one. See ADULTERATION.

ORGANIC ANALYSIS.—The analysis of that class of substances commonly known as organic compounds, is a process which requires to be varied very considerably, according to the nature of the compound to be analysed, and according to the elements which it contains. Every so-called organic compound contains carbon as one of its essential constituents, but no sharp distinction, except of a purely artificial kind, can be drawn between organic and inorganic carbon compounds. Those elements which, besides carbon, are pre-eminently conspicuous in the composition of the majority of undoubtedly organic compounds, are hydrogen, oxygen, and nitrogen. Many hundreds of compounds exist which contain only carbon and hydrogen; some very large classes of compounds contain oxygen in addition to these two; while

compounds containing nitrogen, in addition to hydrogen, or oxygen, or both, are also very numerous. Besides these large classes, however, many organic compounds exist, containing sulphur, phosphorus, chlorine, bromine, iodine, or other non-metallic element, or almost any of the known metals.

When a new compound has been isolated in what is believed to be a pure state, it is of the utmost importance, from a chemical point of view, that its qualitative and quantitative composition should be determined. From its origin, it is often possible to say what elements it is likely or unlikely to contain, but a qualitative search must be made to prove the presence or absence of particular elements. In order to test for carbon, and simultaneously for hydrogen, the substance is mixed with black oxide of copper (cupric oxide), which, as well as the substance itself, must be quite free from moisture, and then heated to redness in a hard glass tube. Carbon is oxidised, by the oxygen of the cupric oxide, to carbonic acid, which may be recognised by passing it through a small bent tube, containing in the bend a few drops of lime-water, when a white precipitate of calcium carbonate is produced; hydrogen is also oxidised, forming water, drops of which will condense in a cold glass tube placed in front of the one containing the lime-water. The test usually employed in searching for nitrogen, is to heat a small quantity of the substance with a fragment of sodium in a narrow glass tube, then to grind up the tube and its contents under water, and to seek in the solution thus obtained for the presence of sodium cyanide. The presence of oxygen may be ascertained by heating the substance to be tested, to a red heat in a current of pure and dry hydrogen gas, and observing the formation of water. The methods of testing for other elements cannot be discussed at length, but the general rule is to destroy the organic matter, either by heating alone, or by the action of powerful oxidising agents, such as nitric acid, and then to test by suitable means, as in inorganic analysis, for the products formed by such heating or oxidation.

The simplest case of the quantitative analysis of an organic compound is that when the compound contains carbon and hydrogen only, or these two along with oxygen. In such a case, the method almost universally adopted now is what is known as the *open tube combustion* method, or the combustion of the substance in a tube contain-

Apparatus fitted for an Open Tube Combustion :

ab is the combustion tube shown separately, the ends being fitted with rubber stoppers, bored for the introduction of glass tubes; *f* is cupric oxide confined by stoppers of asbestos at *ee*; *d* is the 'boat' to contain the substance, and *c* a piece of glass to narrow the air passage and prevent backward diffusion; *k* is the gas furnace; *g*, *h*, and *j* contain solution of caustic potash, pieces of solid caustic potash, and pumice-stone soaked in sulphuric acid respectively, to purify and dry the current of air; the stand *p* supports the tubes *l*, *m*, and *n*, which absorb the products of the combustion; *o* contains a drop of strong sulphuric acid, and serves to indicate the rate of exit of gas bubbles

ing red-hot cupric oxide, through which a current of air or oxygen is passed during the operation. For the purpose of such a combustion, a tube of highly infusible glass is employed, some thirty inches long, open at both ends, and having an

internal bore of about half an inch. This tube is filled, from the middle to within two inches or so of one end, with coarsely powdered cupric oxide, which is held in its place by two plugs of not too tightly packed asbestos. The ends are fitted with

stoppers of red rubber, perforated so as to admit of the introduction of narrow glass tubes. Thus arranged, the tube is placed horizontally, with the ends projecting about two inches at each side, in a gas furnace (which is the modern representative of the old charcoal furnace at one time exclusively used), and carefully heated up to bright redness, while a current of dry air or oxygen is passed slowly through it, entering at the end which is not occupied by the cupric oxide, and passing out again at the other end. This preliminary ignition is to remove all traces of organic matter and moisture from the tube itself, and its contents, and it is continued for half an hour or longer. The current of air or oxygen is purified from traces of carbonic acid, and from aqueous vapour, by passing it first through strong solution of caustic potash contained in a washing-bottle, next through a tube containing pieces of solid caustic potash, and finally through one or more tubes containing fragments of pumice moistened with strong sulphuric acid. When the ignition has been continued for a sufficiently long time, part of the gas is turned out, so as to allow the front part of the tube to cool, the cupric oxide, however, being kept hot. After this, the weighed tubes, which are to collect the products of the combustion, are fitted air-tight to the exit end of the combustion tube. These consist of, first, a U tube of special shape, packed with fragments of pumice moistened with strong sulphuric acid, in which the whole of the water is condensed and collected; and second, one or more U tubes containing granulated *soda-lime** in which carbonic acid is absorbed. Before escaping from the last soda-lime tube, the unabsorbed gases pass through a short layer of fragments of dried calcium chloride, to retain water vapour liberated by the action of carbonic acid on the soda-lime. When the front part of the tube is nearly cold, the india-rubber stopper is removed, the weighed quantity of the substance to be analysed, contained in a platinum or porcelain 'boat,' is introduced into the tube, and the stopper rapidly replaced. A slow current of dry air being again passed through the tube, the substance is then very slowly and cautiously heated, so as to cause it to burn slowly; and, by degrees, the whole of the cool part of the tube is heated, eventually to bright redness, and this heat is maintained until the substance is completely burned, oxygen being passed through to complete the process if necessary. The products of combustion are entirely swept out of the combustion tube, and into the weighed tubes, by continuing the air-current for some time after the substance is entirely burned. These tubes are then detached, allowed to cool, and weighed. The percentages of hydrogen and carbon in the substance are calculated from the weights of water and carbonic acid respectively obtained.

As a rule, the percentage of oxygen contained in an organic substance is estimated by difference. Several methods for the direct determination of oxygen have been proposed, but none of these have come into common use.

Nitrogen is determined either by converting it into ammonia and ascertaining the quantity of this which is produced, or (when the nature of the substance to be analysed requires it) by carrying out a combustion of a special kind, with cupric oxide in a tube closed at one end, measuring the volume of the nitrogen which is obtained, and, by aid of a simple formula, calculating its weight. The conversion into ammonia is effected either by heating the substance to redness with soda-lime or by first boiling it with sulphuric acid and then

boiling the ammonium sulphate so formed with excess of caustic alkali; but these methods are not applicable to all substances, and hence the combustion method must often be employed.

The methods employed to determine the quantities of elements less frequently occurring as constituents of organic compounds, such as sulphur, phosphorus, iodine, &c., are very numerous, and some are very complicated; hence they could not profitably be discussed here in any detail. Suffice it to say, as has been said already under the qualitative testing, that the first step is almost invariably one involving the destruction of the organic compound as such, by some oxidising process, after which the products can be treated exactly as would be done in the case of inorganic quantitative analysis.

Analysis, SPECTRUM. See SPECTRUM.

Analyst, PUBLIC. In the Sale of Food and Drugs Act (1875), it is enacted that certain specified local authorities may appoint one or more persons possessing competent knowledge, skill, and experience, as analysts of all articles of food and drugs sold within their district. The amending Act of 1899 deals chiefly with agricultural products, but gives power to the Local Government Board or the Board of Agriculture to put the Acts in force in any case where the local authority neglects to appoint a public analyst.

In section 12 of the Act, it is enacted that any purchaser of an article of food or drug in any place where there is an analyst, shall be entitled, on payment to such analyst of a sum not exceeding 10s. 6d., to have such article analysed by such analyst, and to receive from him a certificate of the result. Private individuals are generally content merely to receive the certificate, and rarely if ever take any further action. In order, therefore, that the Act should not become inoperative, and that dealers guilty of selling adulterated food might be tried and punished for the offence, inspectors were appointed, whose duty consists in going to the various shops and other places where food is sold, making purchases of the different articles therein exposed for sale, and submitting these to the public analyst for examination. If the analyst certifies that any of the substances submitted to him have been adulterated, the inspector must take steps to have the seller prosecuted. A case is prepared for trial, and if the judge is satisfied that an offence within the meaning of the Act has been committed, he convicts the accused, who is then liable in a penalty not exceeding, for a first offence, £20; second, £50; third or subsequent, £100. The existence of these functionaries, however, does not prevent any member of the public from purchasing any article of food and submitting it for analysis to the public analyst. Only, if it is intended to take legal action, he must, after the material has been bought and paid for, and is in the buyer's possession, intimate to the seller that it has been bought for the purpose of being analysed, and he must offer to divide it. If his offer is accepted, he must then and there divide it into three portions, each of which must be sealed in the seller's presence. One of the portions so sealed is to be left with the seller, so that he may, if he be so advised, have an analysis made of it on his own account. Another portion is to be taken to the public analyst for analysis, and the third is to be retained intact till after the trial, in order that the judge may, if he deems such a course advisable, direct that it be sent for analysis to the government analysts at Somerset House. In the event of the seller not accepting the offer of the buyer to divide the material, the buyer must then carry the whole to the analyst, who will divide it into two portions, one of which

* Soda-lime is a mixture of sodium and calcium hydrates, prepared by slaking quicklime with caustic soda solution, and drying up the product.

he will retain, the other he will seal and return to the buyer.

Although public analysts are appointed in the first place by local authority, their appointment is not legal until it has been confirmed by one of his Majesty's principal secretaries of state; and an analyst, when once appointed, cannot be removed without a like sanction from one of these officials. See ADULTERATION.

Anam. See ANNAM.

Anamirta. See COCCULUS INDICUS.

Anamne'sis (Gr., 'recollection'), specifically, recollection of a state of Pre-existence (q.v.; and see PLATO); also a patient's remembrance of the first symptoms of his illness.

Ananas. See PINE-APPLE.

Ananiev, a town of Ukraine, in the government of Kherson, 100 miles N. of Odessa; pop. 20,000.

Anapa, a Black Sea Kuban port, 50 miles SE. of Yenikale; pop. 8000.

Anaphylaxis, a phenomenon of serum-therapy, arising when an animal has had a considerable quantity of a serum injected. Such an animal, afterwards receiving a much smaller quantity, sometimes dies, as if the previous injection, so far from producing immunity, had rendered it more sensitive to the poison.

Anarchism (Gr. *an-*, 'not,' and *archē*, 'rule') properly means the negation of government, and has quite a distinct meaning from *Anarchy* in the usual acceptance of the word. In its ordinary sense, anarchy is a state of society without any regular government, when social and political confusion prevails. *Anarchism*, on the other hand, is the name adopted by a phase of revolutionary theory. The acknowledged father of anarchism is Proudhon. Proudhon was an eccentric and paradoxical thinker, with a passionate and exaggerated love of individual freedom. Government of man by man he considered to be oppression, an interference with freedom. He therefore regarded a form of society without government, in which every man should be a law to himself, as the goal of human evolution. Since Proudhon, the most prominent expounder of the anarchist theory has been the Russian Bakunin (q.v.), who, in various writings, and by an active propaganda, diffused it in most of the Latin countries. His ideas may be traced in the Paris Commune, in Spain during the risings of 1873, in Italy, and in French Switzerland. Well-known representatives of it are the Russian man of science, Prince Kropotkin, and the distinguished French geographer, Elisée Reclus. At the anarchist trial at Lyons in 1883 the accused, including Kropotkin, drew up a declaration which may be regarded as the most important statement of their position.

It is not easy to define the anarchist views, but the following are undoubtedly the leading points: They desire complete liberty for all men. They object to all authority, whether monarchic or republican, whether based on divine right or universal suffrage, for history teaches that all government tends to privilege and oppression. In all human relations their ideal is one of free contract, perpetually subject to revision and cancellation. But such an ideal of freedom cannot be realised in a society where land and capital are the monopoly of a class. Land and capital must therefore be the common property of society, at the disposal of every one. They wish equality, equality of fact, as a corollary, or rather fundamental condition, of liberty; that all men may have daily bread, knowledge and work, independence and justice. As the essential means for bringing about this new evolution of society, they insist on the uni-

versal diffusion of knowledge. When natural laws shall have been understood, and the knowledge of them universally diffused among men, there will be no need for external authority. Natural laws being recognised by every man for himself, he cannot but obey them, for they are the laws also of his own nature; and the need for political organisation and administration will at once disappear. With reference to the old system of society which stands in the way of the new era, Bakunin recommends a most unsparing policy of destruction. As the theory of anarchism is unlimited freedom and the negation of government, it is difficult to realise how society in its wider aspects can be carried on in consistency with it. Anarchists, however, seem to agree in believing that the free commune or free association will be the fundamental form of society; and there will be a free federation of free associations, leading to the universal and international solidarity of the workers of all countries, and transcending all the limits and obstacles raised by so-called patriotism and national jealousy. Society will be a free grouping of peoples in accordance with natural needs freely realised. But the future form of society is the work of coming generations, and will proceed out of the movement and life of the people. The work of the present is the removal of the old, and the universal diffusion of true science among the masses. It will be seen that anarchism has two aspects: it has a political theory, the negation of government or of external authority; and it has an economic theory as to land and capital, which is common to it with socialism. It has also come to have another aspect—that with which it is now usually identified—war on human society as at present constituted, hatred of the *bourgeois* and propertied classes as such, and a systematic effort to establish, especially by means of explosives, a terrorism such as was formerly associated with extreme Russian Nihilism (q.v.), and the Irish dynamite attempts. Notable outbreaks have been those at Chicago (q.v.) in 1886; in Spain and in France in 1892 (especially those for which Ravachol was responsible); in the Barcelona theatre in 1893; in the French Chamber of Deputies (Vaillant, 1893); in a Parisian café (Henri, 1894); the destruction of Bourdin by his own petard at Greenwich (1894). Anarchist daggers cut short the lives of President Carnot (1894) and the Empress of Austria (1898). In 1900 King Humbert of Italy was shot by an anarchist, and in 1901 President McKinley. On the other hand, Tolstoi, who taught non-resistance to evil, was an anarchist.

See SOCIALISM, DYNAMITE, NIHILISM; several works by Kropotkin; American books by Schaack, Parsons, Lum, and Mackay (1889-94); Felix Dubois, *Le Péril Anarchiste* (1895; trans. 1894); Zenker, *Der Anarchismus* (1895; trans. 1898); Vizetelly, *The Anarchists* (1912).

Anas. See DUCK.

Anastasius, the name of four popes, the first and most eminent of whom held that office for only three years (398-401).—For the Emperor Anastasius I. (491-518), see BYZANTINE EMPIRE. Anastasius II. (713-715), deposed by his soldiers, retired to a cloister, and an attempt to recover his crown cost him his life.

Anastomosis, the union of the vessels which carry blood or other fluids; also the junction of nerves. The veins and absorbents anastomose to form large single trunks, as they approach their ultimate destinations. The arteries break up into small branches for the supply of the tissues, and each small vessel, again, communicates with others given off above and below. Round each large joint there is very free anastomosis, so that the safety of the limb beyond may not be

entirely dependent on the single arterial trunk passing into it, exposed as it is to all the obstructive influences of the different movements of the joint. If the main artery is permanently obstructed, the anastomosing vessels enlarge, so as to compensate for the loss; but after a time only those whose course most resembles the parent trunk continue enlarged, and the others gradually regain their ordinary dimensions.

An idea of the profusion of this anastomosing system may be formed from the fact that if the innominate artery (or great vessel destined for the supply of the right upper half of the body) be tied, and those on the left side injected with size and vermilion, the injection will flow freely into the arteries of the right arm, through branches as minute as they are numerous.

Arteries
anastomos-
ing.

Anathema (Gr. *anathēma*, 'a thing set up'), a word originally signifying some offering or gift to the gods, generally suspended in the temple. It also signifies a thing devoted; a thing devoted to destruction (the equivalent of the Hebrew *Cherem*); and was ultimately used in its strongest sense, implying perdition, as in Rom. ix. 3; Gal. i. 8, 9. In the Catholic Church, from the 9th century, a distinction has been made between excommunication and anathematising; the latter being the extreme form of denunciation against obstinate offenders. The first general council (Nice, 325 A.D.) anathematised those who held the Arian heresy. It thus declared that they were excluded from the communion of the church, and that if they persisted in their offence they must perish eternally (see EXCOMMUNICATION).—*Anathema Maranatha* (1 Cor. xvi. 22) is not, as commonly understood, a more fearful kind of curse; the Syriac words, *Maran athā* ('Our Lord cometh'), should, according to the best authorities, be read as a separate sentence, as in the Revised Version.

Anatolia, a Greek name for Asia Minor (q.v.). The word is derived from the Gr. *Anatolē*, 'the rising of the sun,' 'the east;' so that as a word it has the same meaning, though not the same application as the Italian *Levante*, used of all the countries lying east of the Mediterranean; and the same as *Orient*, derived from the Latin, used of the 'East' in the widest sense. From Anatolia is formed the Turkish *Anadōli*, generally applied to the western and northern portions of Asia Minor.

Anatomy (Gr. 'a cutting up or dissecting') is the science of the form and structure of organised bodies, and is acquired practically by separation of the parts of a body, so as to show their distinct formation, and their relations to each other. It is therefore a branch of the science of Biology, which consists of two great divisions—the Anatomy of animals, styled *Zootomy*, and that of plants, *Phytotomy*. The various divisions of Anatomy will be found at the end of the following historical sketch.

History of Anatomy.—It is difficult to determine the date at which this science began to be cultivated, but it is probable that from the earliest times some persons took advantage of favourable circumstances to acquaint themselves with it. Alcmaeon of Crotona, a disciple of Pythagoras, and Democritus are said to have dissected animals with the view of obtaining comparative knowledge of human anatomy. Hippocrates (q.v.), born at Cos about 460 B.C., though the father of medicine, is less justly regarded as the father of anatomy, as

his views of the structure of the human body are very superficial and incorrect. Aristotle, born 384 B.C., is really the founder of the science. He seems to have based his systematic views of comparative anatomy on the dissection of animals, but does not appear to have dissected men. He first gave the name *aorta* to the great artery. No real progress in human anatomy was made, owing to the researches being confined to animals, till the time of Erasistratus (250 B.C.), who was the first to dissect human bodies—the bodies of criminals. Herophilus also is said to have dissected living subjects. Celsus (63 B.C.) in his *De Medicinā* wrote much on anatomy.

Galen (131 A.D.) dissected apes, as being most like human subjects, though he occasionally obtained bodies of persons found murdered; and his writings show a knowledge of human anatomy. Soranus, Oribasius, Nemesius, Meletius, and Theophilus based their anatomical works mainly on Galen. Anatomy made small progress among the Arabs, as their religion prohibited contact with dead bodies. Avicenna (980 A.D.), born in the province of Khorassan, was a good osteologist, and described some structures not alluded to by Galen.

The medical school at Bologna became famous in the 13th century, as did also those at Padua and Salerno; but no very material progress was made in anatomy. Mondino, born at Milan, 1315, professed anatomy there, and is considered the real restorer of anatomy in Italy. Then came Guy de Chauliac, Mathæus de Gradibus (1480), Gabriel de Zerbis (1495), Achillini (1512), Berenger of Carpi (1578), Etienne, Massa, and Sylvius (1539). An epoch is made by Andrew Vesalius (q.v.), who published a great work on anatomy before he was 28 years of age.

William Horman of Salisbury wrote, in 1530, *Anatomia Corporis Humani*. Thomas Gemini of London, in 1545, engraved upon copper the anatomical figures of Vesalius, which had appeared in Germany upon wood. Gemini suppressed the name of Vesalius, though using his figures and descriptions. Thomas Vicary, in 1548, is said to be the first who wrote in English on anatomy; he published *The Englishman's Treasure, or the True Anatomy of Man's Body*. Franco (1556), Valverde, and Columbus wrote works of great merit on anatomy. In 1561 Gabriel Fallopius (q.v.) taught with great distinction at Padua, and made many original discoveries.

In the 17th century, progress was rapid. Harvey, in 1619, discovered the circulation of the blood, and the microscope was employed to detect the structure of minute vessels. Aselli, in 1622, discovered and demonstrated the existence of the lymph-vessels. The glandular organs were investigated by Wharton, while Malpighi, Swammerdam, and the illustrious Ruysch, by the use of injections and the aid of the microscope, gave a new impulse to research in the minute structures. Eminent names in the history of anatomy are numerous in the 18th century. In Italy, which still retained its former pre-eminence, we find Pacchioni, Valsalva, Morgagni, Santorini, Mascagni, and Cotunni; in France, Winslow, D'Aubenton, Lieutaud, Vieq d'Azyr, and Bichat, the founder of general anatomy; in Germany, Haller and Meckel prepared the way for greater achievements in the 19th century; in Great Britain, Cowper, Cheselden, Hunter, Cruikshank, Monro, and Charles Bell contributed to the progress of the science; while Holland was worthily represented by Boerhaave, Albinus, Camper, Sandifort, and Bonn. On the boundaries of the two centuries, we find the names of Sömmerring, Loder, Blumenbach, Hildebrand, Reil, Tiedemann, and Seiler.

The necessity of a union of theory and practice

has led to the study of **PATHOLOGICAL ANATOMY** (the dissection and study of structures as modified by diseases). The origin of this branch of anatomy may be traced back to ancient times in Egypt; and amongst the Greeks some anatomico-pathological observations are found. During the general revival of science in the 16th century, many notices of pathological anatomy occur. Morgagni (1767) must, however, be regarded as the true founder of Pathological Anatomy. He was worthily followed by Lieutaud, Sandifort, Hunter, Baillie, Meckel the younger, and others. The recent change of direction given to the study of Pathological Anatomy, which is now properly regarded as a means towards practical improvements in medicine, must be ascribed to Bichat and the pupils of Broussais, among whom may be mentioned the names of Laennec, Cruveilhier, Louis, Andral, Lobstein, Lebert, Virchow, and Bennett.

Theoretical anatomy is divided into General and Special. **GENERAL ANATOMY** gives a description of the elementary tissues of which the systems and organs of the body are composed, as preliminary to an examination of them in their combined state in the various organs: it also investigates their laws of formation and combination, and the changes which they undergo in various stages of life. This branch of study may also be styled **Structural or Analytical Anatomy**, and has been first developed in recent times, especially by Bichat (1801) and Beclard, who have been followed by J. Müller, Goodsir, Henle, E. H. Weber, Schwann, Valentin, and many others. In our day, microscopic investigation has been successfully applied to the study of elementary textures. See **HISTOLOGY**.

SPECIAL ANATOMY (styled Descriptive by the French writers) treats of the several parts and organs of the body in respect to their form, structure, and systematic connection or relation with each other. The arrangement of the several parts and organs in an order deduced from their similarity in structure or use, constitutes **SYSTEMATIC ANATOMY**. According to this mode of study, which is essential as an introduction to physiology, anatomy has been divided, though not with scientific precision, into six branches of study. 1. *Osteology*, which treats of the bones, including the cartilages of the joints (chondrology). 2. *Arthrology*, which describes the ligaments, or bands, that unite the bones of various joints. The bones, with their cartilages and ligaments, form a framework, which supports the external soft parts, and within which the vital organs are suspended and protected from injury; they are also arranged in a mechanical system as organs of locomotion. 3. *Myology* explains the system of the muscles, which, by their contractile power, serve to impart motion to the bones and joints; while, like the bones, they contribute to form the cavities of the body, and to protect the internal organs. Their form also serves to produce the external shape and symmetry. 4. *Angiology* describes the vessels or ducts, with their complex network and ramifications, spreading over most parts of the body, and divided into two great systems: (a) the blood-vessels with the heart, a fleshy organ propelling the blood through the pulsating vessels or arteries, from which it returns to the heart, after circulation through the veins; (b) the lymphatics, by means of which a certain fluid (lymph) is passed through a series of organs named lymphatic glands, and afterwards enters the large veins at the root of the neck. The lacteals, which absorb the chyle from the intestine, also belong to this system of vessels. 5. *Neurology*, or the doctrine of the nerves, describes the nervous system, as divided into, *first*, the two central masses of the brain and the spinal

cord; *second*, the ramifications of nerves running from the brain and spinal cord to almost all points of the surface; and *lastly*, the order of nerves having a peculiar structure, and styled the ganglionic system of nerves. 6. *Splanchnology* describes the viscera or organs formed by combination of the distinct systems of veins, nerves, lymphatics, &c., and mostly situated in the cavities of the body. These are divided into five groups—viz.: (a) the organs of the senses—sight, hearing, smell, taste, and touch; (b) of voice and respiration—nostrils, mouth, larynx, trachea, and lungs, with the thyroid gland, the thymus gland, and the diaphragm; (c) digestive organs—the mouth, with its salivary glands, the throat, gullet, the stomach, the intestines, with the liver, spleen, and pancreas; (d) the urinary organs—kidneys, ureters, bladder, and urethra; (e) sexual organs of both sexes.

Special anatomy may be treated in another mode: by an arrangement made in accordance with natural divisions, or by imaginary lines dividing the body into several regions—as the head, the trunk, and the extremities. Again, the trunk may be subdivided into neck, thorax, and abdomen; and in each of the main regions, several subdivisions may be made. This system of arrangement may be styled **Topographical Anatomy**, and is also known as **Surgical Anatomy**, on account of its importance as the basis of operative surgery. It was the eldest of the Monros of Edinburgh University who first gave this branch of the study its due prominence.

COMPARATIVE ANATOMY, the investigation and comparison of the structures of two or more animals, has always preceded anthropotomy, or dissection of the human subject, but was first treated systematically as a distinct science by Cuvier and his pupil, Meckel the younger. Blumebach, Tiedemann, Home, Blainville, Geoffroy St Hilaire, Carus, Oken, Goethe, Owen, Goodsir, Müller, Wagner, Siebold, Bowman, Todd, Milne-Edwards, Von Baer, Gegenbaur, Kölliker, Remak, Czermak, Leydig, Frey, Schwann, Haeckel, Kovalevsky, Agassiz, Van Beneden, Burmeister, Carpenter, Allman, Sharpey, Allen Thomson, Huxley, Turner, and Flower, may be named as eminent contributors to this branch of science.

ANATOMY FOR ARTISTS is studied with reference to the effects produced by internal structure on the external form, and describes the organs, especially the muscles and tendons, not only in a state of rest, but also as modified by passion, action, and posture.

PRACTICAL ANATOMY includes *Dissection* (q.v.) and the making of *Preparations*. *Preparation* consists in dividing parts or organs, so that their respective forms and positions may be clearly shown. Organs or parts thus treated are styled *Anatomical Preparations* of bones, muscles, vessels, nerves, &c. For example, a bone-preparation is made by clearing away all muscular and other adhesions; the whole structure of the bones, thus prepared and bleached, when connected by wires in its natural order, forms an artificial *skeleton*. Preparations of the soft parts are either dried and varnished or preserved in spirit.

A series of such specimens, arranged in proper order, forms an *Anatomical Museum*. The valuable collections made by Ruysch, Rau, Loder, Walter, John and William Hunter, Meckel, Sömmering, Dupuytren, and Goodsir, are all now public property. As it is impossible to preserve thus all parts in their integrity for any great length of time, artificial copies in wood, ivory, papier-mâché, and wax are made with great exactitude. But, apart from dissections and preparations of the natural organs, the most general and available assistance in the study of anatomy is found in anatomical engravings and plates on wood and

copper. This assistance was known in ancient times. Aristotle affixed to his works on anatomy some anatomical drawings, which have been lost. In the 16th century the greatest artists—Leonardo da Vinci, Michelangelo, Raphael, Titian, and Durer—gave their aid in designing anatomical figures. See the writings on anatomy of Meckel, Cruveilhier, Hyrtl, Rauber, Bardeleben, Tillaux, Poirier, Testut; in Comparative Anatomy, Carus, Wagner, Cuvier, Gegenbaur, Milne-Edwards, Owen, Huxley. Among English works may be mentioned those by Lizais, Jones, Cooper, Richard Quain, Ellis, Ford, Gray, Morris, Treves, Cunningham, and Symington, in *Special Anatomy*; by Morton and MacLise, in *Surgical Anatomy*; and by Baillie and Bright, in *Pathological Anatomy*.

The anatomy of the various parts and organs of the body will be found described, frequently in conjunction with their physiology, under their proper heads. Among the more important articles are the following:

Abdomen.	Epidermis.	Larynx.	Peritoneum.
Aorta.	Eye.	Leg.	Placenta.
Artn.	Fœtus.	Liver.	Respiration.
Arteries.	Foot.	Lymphatics.	Ribs.
Bile.	Glands.	Man.	Shoulder.
Blood.	Hair.	Medicine.	Skeleton.
Bone.	Hand.	Muscle.	Skin.
Brain.	Heart.	Nervous System.	Skull.
Capillaries.	Hip-joint.	Nose.	Spinal Cord.
Cartilage.	Histology.	Ovariectomy.	Spleen.
Cells.	Horn.	Palate.	Teeth.
Circulation.	Joints.	Pancreas.	Tongue.
Digestion.	Kidneys.	Pelvis.	Trachea.
Ear.	Knee.	Pericardium.	Veins.

Anatomy, in Law. The difficulty of obtaining a sufficient supply of human bodies for dissection for purposes of surgical and medical instruction, gave rise, in the beginning of the 19th century, to the Resurrectionists (q.v.), and to the horrible crimes for which Burke was executed in 1829. This matter was accordingly made the subject of statutory legislation, and is now governed by the Anatomy Acts of 1832 and 1871. These Acts authorise the Home Secretary to grant licenses to practise anatomical dissection to any qualified medical practitioner, or any teacher or student of anatomy. The supervision of places where anatomical examination is conducted is entrusted to inspectors of anatomy in the several districts, who make quarterly returns (unprinted) to the Home Office of the human subjects used in each district. In the absence of a contrary wish expressed by the deceased or a surviving relative, the Acts authorised an executor to submit the body of the deceased to dissection, but where the deceased has directed this to be done, the Acts recognised the right of near relatives to object. Bodies are not to be removed for examination until forty-eight hours after death, nor without a certificate by the medical attendant, stating, according to the best of his knowledge or belief, the manner or cause of death. The person receiving the body must intimate the fact to the inspector, and must afterwards send to him a certificate of decent burial. The period of time within which such certificate of burial must be sent is fixed by statutory order (*Anatomy Orders*, 1916). The Acts do not apply to any post-mortem examination of any human body required or directed to be made by any competent legal authority.

Anatta. See ANNATTO.

Anaxagoras, one of the most eminent Ionic philosophers, was born at Clazomenæ, in Ionia, 500 B.C. He belonged to a wealthy family, but devoted himself exclusively to intellectual pursuits; and, still young, moved to Athens, where, in the course of a thirty years' sojourn, he acquired a high reputation, and had many illustrious pupils, among

whom were Pericles, Euripides, and possibly Socrates. But at last, his explanations of physical phenomena by natural causes rendered him suspicious to the polytheists; he opposed divination and astrology; and, being accused of impiety towards the gods, he was condemned to death. His sentence, however, was commuted into banishment for life, through the eloquence of Pericles. He withdrew to Lampsacus, on the Hellespont, where he died in 428.

It is not easy to ascertain what were the opinions of Anaxagoras in philosophy. Fragments merely of his works have been preserved, and even these are sometimes contradictory. Of one thing we are certain, that he had a deeper knowledge of physical laws than any of his predecessors or contemporaries. He also arrived at some tolerably accurate conclusions regarding the cause of the moon's light, of eclipses, earthquakes, meteors, of the rainbow, of wind, and of sound. His great contribution to ancient philosophy, however, was his doctrine as to the origin of all things. He held that all matter existed originally not in the form of the so-called elements, but in the condition of atoms; that these atoms, infinitely numerous and infinitesimally small, had existed from all eternity, and that order was first produced out of this infinite chaos of minutiae through the influence and operation of an eternal intelligence (Gr. *nous*). He also maintained that all bodies were simply aggregations of these atoms, and that a bar of gold, or iron, or copper was composed of inconceivably minute particles of the same material; but he did not allow that objects had taken their shape through accident or blind fate, but through the agency of this 'shaping spirit' or *Nous*, which he described as infinite, self-potent, and unmixed with anything else. '*Nous*,' he again says, 'is the most pure and subtle of all things, and has all knowledge about all things, and infinite power.' His theory of the *Nous* was vague, but makes a great advance in the direction of theism, though personality is not attributed to the *Nous*. Anaxagoras marks a great turning-point in the history of speculation: while, on the one hand, his doctrine of the *Nous* passed to Aristotle, his doctrine of atoms prepared the way for Democritus (q.v.) and the Atomic School. With Anaxagoras, too, philosophy left its old home in Ionia, and established itself in its most famous seat—in Athens. His most notable work, *On Nature*, has survived only in fragments. See Zeller or Burnet (1892) on early Greek philosophy.

Anaximander, a Greek mathematician and philosopher, successor of Thales as head of the physical school of philosophy, was born at Miletus, 611 B.C., and died in 547. He is said to have discovered the obliquity of the ecliptic, and he certainly taught it. He appears to have applied the *gnomon*, or style set on a horizontal plane, to determine the solstices and equinoxes. The invention of geographical maps is also ascribed to him. As a philosopher, he speculated on the origin (*archê*) of the phenomenal world, and this principle he held to be the infinite or indeterminate (*to apeiron*). From it he conceived all opposites, such as hot and cold, dry and moist, to proceed through a perpetual motion, and to return to it again. Of the manner in which he imagined these opposites to be formed, and of his hypothesis concerning the formation of the heavenly bodies from them, we have no sufficient information. Some of his particular opinions were, that the sun is in the highest region of the heavens, is in circumference twenty-eight times greater than the earth, and resembles a cylinder from which flow continual streams of fire; also that the earth is of the form of a cylinder, that it floats in the midst of the universe, and that it was formed by the drying up of moisture by the sun.

Anaximenes, a Greek philosopher of the Ionic school, was born at Miletus, and died about 500 B.C. He held *air* to be the first cause of all things, or the primary form of matter, whence all things were formed by compression.

Anaximenes, a Greek historian, rhetorician, and epic poet, born at Lampsacus, accompanied Alexander in Persia, and was probably the author of the *Rhetorica ad Alexandrum* attributed to Aristotle.

Anbury is a disease in the turnip, which is produced by a fungus *Plasmodiophora*, belonging to the family of slime-fungi, *Myxomycetes*. It attacks the plant most readily when its full vigour is restricted by some unfavourable condition of growth, such as when it is planted too frequently on the same land; when the soil is deficient in some necessary ingredient; or when it is in an unsuitable mechanical condition, the result frequently of improper or unseasonable cultivation. It is identical with club-root in cabbages. It is commonly termed *finger-and-toe*, but this name is also applied to another condition in turnips in which the bulb branches out into numerous tap-roots, the skin remaining whole. Anbury produces a scabbed and broken condition of the skin, and tubercular enlargements on the roots at the base of the bulb. Both affections may exist on the same plant. Anbury frequently causes almost complete failure of the crop. In some cases maggots are found in the affected parts, but they are only attracted by the degenerate structure, and have nothing to do with the disease. It is accompanied with an offensive smell, resulting from the decay of the injured parts. Anbury may be noticed at a distance by the drooping and unhealthy appearance of the leaves during sunshine. There is no cure, but preventive means may be successfully employed, such as planting turnips on the same land only after long intervals; avoiding treading of the land while it is wet; working the soil and planting good seed at the proper season; supplying manures sufficient to make good the soil's deficiencies; avoiding the consumption by cattle of roots on land which is soon to grow turnips; also dressing land with lime, preferably a year or more before the crop is to be sown. The first dressing is not always efficacious, but a second application at the same period of the rotation when it comes round again is usually successful. The workings of the disease are yet so far mysterious: although the fungus is known, the actual conditions which encourage its development are not fully understood. For instance, in some districts (parts of Gloucester, and East Barns, Dunbar) turnips can be grown year after year on the same land, and yet not take the disease; while in other places (light soils particularly), to repeat the crop oftener than once in five or six years is most dangerous.

Ancelot, JACQUES-ARSENE-POLYCARPE-FRANCOIS, a French dramatic poet, was born at Havre, February 9, 1794. His first success was the tragedy of *Louis IX.* (1819), which procured him the post of librarian at the Arsenal, and a pension from the king. In 1826 he accompanied Marshal Marmont to St Petersburg, and published next year his *Six Mois en Russie*, part in verse, and the novel, *L'Homme du Monde*. After the revolution of July had deprived him of his place and pension, he brought out upon the stage a succession of little comedies and vaudevilles, most of which had but little merit. His tragedy *Maria Padilla* opened to him, in 1841, the doors of the French Academy. Shortly after appeared his *Epîtres Familiales*, distinguished by point and elegance. He died 7th September 1854.

Ancestors, WORSHIP OF, the chief element in the religions of perhaps the larger half of mankind at the present moment. It arises naturally from the primitive conception of a soul during life animating

the body and exercising influence over it, and after death merely retaining its power, continuing into the unseen world the life and social relations of the living world. The dead chief now passes into a deity, goes on protecting his clan and receiving service from them, and continues to keep the same temper as in mortal life. So that it is not mere family affection, but actual fear, that impels this reverence among the North American Indians, the ancient Aztecs, the negroes in Guinea, the natives of Polynesia, and most strongly among the Zulus, who conquer in battle with the help of the 'amatongo,' the spirits of their ancestors, and reach back through a series of divine ancestors to the earliest ancestor and creator of man, the Old-Old-one, Unkulunkulu. The primitive mind, it would seem, makes no essential distinction between the divine nature, the human nature, and the animal nature, and freely worships visible natural objects for the sake of the spirits resident in them. The conception is due to Animism (q.v.), and develops into a more spiritual point of view, in which the indwelling spirit is considered as having an independent existence detached from the object with which it was confounded. The most complete treatment of the subject of ancestor-worship is to be found in Sir J. G. Frazer's Gifford Lectures, published as *The Belief in Immortality and the Worship of the Dead* (vol. i. 1913).

The worship of ancestors is really a subdivision of animism. The spirits of the dead are assimilated to the spirits that reside in the objects of nature, at first revered like them, then more than them. Where direct worship of the objects of nature unfolds itself into a rich dramatised mythology, that is to say among the races most endowed with the speculative and æsthetic faculties, such as the ancient Greeks, animism and the worship of ancestors develop but feebly. But where on the contrary, as in China, mythology remains infertile; or where, as among many savage races, it never gets beyond its embryonic stage, animism becomes preponderant, and often, by it and along with it, the worship of ancestors. In China it is the dominant religion. Ancestors still have their temples and their offerings, and remain so present that the virtues or the crimes of their descendants are always considered in relation to them, as covering them with honour or infamy. The Hindu pays his offerings to the *pitris* (*patres*) or divine manes, and looks to them for success and happiness. In Europe, the most conspicuous example was the usage of the ancient Romans. Their *manes* or ancestral deities were embodied as images, set up as household patrons, and appeased with offerings. They were counted among the gods of the lower world, and tombs were inscribed D.M., 'Dis Manibus,' sometimes seen as a strange survival in Christian epitaphs. And in the crowd of saints in modern Christendom, with specialised functions, deemed capable of interfering to help the spiritual interests of their votaries, we see at least with what marvellous tact new ideas were fitted to the old.

The universality of ancestor-worship has led Herbert Spencer to the opinion that it was the origin of religion everywhere. His view is a kind of revival of the old Euhemerism (q.v.), which explained the myth as containing an element of historical truth, its figures as enlarged portraits of real men and women, and its gods as merely ancestral ghosts raised to a higher power. He argues that all religious beliefs arose originally out of the erroneous conclusions drawn by primitive man from the ill-understood facts of his own nature, especially in the phenomena of sleep and dreams. These have to the savage as much objective reality as those he has seen when awake. This primi-

tive conception finds further support in the facts of syncope, apoplexy, catalepsy, and other forms of temporary insensibility. During these his 'double,' the soul, has, he believes, been actually absent from the body. These ideas applied to death—but a lengthened sleep or prolonged absence—have engendered the idea of an awaking following regularly after death. Hence primitive funeral rites assume that the dead can eat, drink, and fight anew, and act in everything like a living man. Upon this conception of the state of the dead, in Spencer's view, the savage man's idea of another life is grafted, confirmed as its reality is by the apparition of the dead in dreams. A future life assumes another world—a region of souls, located at first near the place of burial, afterwards above, below, and around the living world. These disembodied souls constantly increasing in number are ordinarily invisible, but are able to manifest themselves from time to time, and to particular individuals. Hence arises naturally the idea that things astonishing, extraordinary, or exceptional, have for their causes the action of the dead spirits—invisible, and in one sense supernatural agents. Since these disembodied spirits still continue influential for good or evil, it is wise to conduct ourselves in such a way as to conciliate their good-will and to deprecate their wrath.

In this elemental consideration, says Herbert Spencer, is the foundation of all religion. But his argument fails to account for many of the facts, and at the outset its fundamental negation may be questioned, that primitive man is incapable of an illusion which consists in taking the inanimate and impersonal for the animate and the personal. He forgets that savage man is full of imagination, and that he is constantly personifying. In fact, personification remains long after the primitive stage is past. In the Græco-Roman society it was the last impress of the old polytheism, and the stars were still animate beings to the eyes of the Stoics and Alexandrians, to a Jew like Philo, and a Christian like Origen. Spencer's theory does not explain the parallelisms and analogies between myths among races of the most widely different degrees of civilisation, nor the difference in the degree of divinity between the first and later ancestors, nor why the dead man has more power for good or evil than he had when alive. His opponents assert that he has not wandered far enough afield for his facts, and that the luminous and convincing appearance of his argument is merely due to the systematic selection of such facts as seem to confirm it, and the no less systematic elimination of their contraries. Certainly the problem of the origin of religion is a much more complex question than this, and ancestor worship is merely a phase of an infinitely wider question.

See Tylor's *Primitive Culture* (1871); Herbert Spencer's *Principles of Sociology*; Caspari, *Die Urgeschichte der Menschheit* (1877); also the articles ANIMISM, ANTHROPOMORPHISM, EUEMERISM, TOTEMISM, RELIGION.

Anchorises. See **ÆNEAS**.

Anchoritherium, a noteworthy animal that lived in Europe and North America during Upper Eocene and Miocene times. It had affinities to the tapir-like *Palæotherium* (q.v.) and true horse. Each foot had three hoofs, the middle one being the largest, and all reached to the ground. The anchoritherium was about the size of a small pony, and is looked upon as one of the ancestors of the existing horse.

Anchor, an implement for retaining a ship in a particular spot, by temporarily chaining it to the bed of a sea or river. Many forms of anchor were made by the ancients; some were merely large

stones; others, crooked pieces of wood, weighted to make them sink in water, the earlier ones acting mainly as weights, and holding the vessel by their own inertia instead of hooking into the ground. The first *iron* anchors are supposed to have been used by the Greeks. As originally made, the anchor had only one fluke or arm for penetrating the ground, and no stock. A large-sized modern anchor, irrespective of recent improvements, comprises the following parts (see fig. 1): The vertical or supporting beam of the anchor is the *shank*, *B*; at the upper end of it is a *ring*, *r*, or a shackle, and just below the ring is a transverse piece called the *stock*, *s s*; the other extremity is the *crown*, *c*, from which branch out two *arms* or *blades*, *g*, in directions nearly at right angles to that of the stock; each arm spreads out into a broad *palm* or *fluke*, *h*, the sharp extremity of which is the *peak* or *bill*, *k*. When the anchor is let go from the ship's side, the crown first strikes the ground; it then falls over in such a manner that one end of the stock rests upon the ground; and the subsequent movements of the ship and the cable cause one or other of the flukes to enter the ground, and take fast hold.

Fig. 1.—Anchor of Admiralty Pattern.

The number of anchors in British ships-of-war varies according to the size of vessel, and the character of the service intended. A large ironclad carries 8 anchors—2 'bowers,' 2 'sheets,' 1 'stream,' 1 'stern,' and 2 'kedges.' Smaller vessels have fewer and smaller anchors; and the 'stream'-anchor of a large ship may conveniently serve as the 'bower' for a smaller, the difference between bower, sheet, and spare anchors being rather in size than in design. Lloyd's rules prescribe the number and weight of anchors which must be carried by ships of different sizes registered in their list, as well as the size and length of their cables, hawsers, and warps.

Some of these particulars are given in the table :

Ship's Tonnage	Anchors.				Stud-Cham Cables.		
	No of Bowers	No of Others	Weight of each Bower * cwt	Admiralty Test tons	Size (Min. max.) inches	Length fath	Admiralty Test tons
100	2	2	5	7½	1½	135	11½
200	3	2	8½	10½	1½	165	20½
500	3	3	18	19	1½	240	37½
1000	3	3	30	28½	1½	270	55½
1400	3	3	34	31½	1½	270	63½
2000	3	3	40	35½	2½	270	76½
2500	3	3	42	37½	2½	300	86½
3000	3	3	45	39½	2½	300	96½

* Excluding stock.

Steamers are only required to carry the anchors and cables which belong to a sailing-vessel of two-thirds their total tonnage.

Many improvements in the shape and construction of anchors of the standard type have been introduced during the past forty or fifty years, of which Rodgers' and Lenox's anchors are the best known; and latterly several novel and improved forms have received extensive adoption—especially in vessels for merchant service. One of the most important changes is that effected under Rodgers' patent of 1838, also known as Honibal's. The arms, instead of being solidly connected to the shank, are movable in relation to it. They pivot about a bolt passing through the crown-piece of the arms and the end of the shank, the latter being fork-shaped to receive the former. The principle will be understood from fig. 2, repre-

senting an early form of Trotman's anchor, which is an improved modification of Porter's, the difference mainly consisting in the shape and disposition of the flukes and their horns or toggles. The advantages of this anchor over those of ordinary make are very considerable. Besides the increased holding-power due to the pivoting of the arm, and diminished chance of the anchor lodging on its stock end, there is less danger of its 'fouling'—in other words, of the cable becoming entangled with the upper fluke—because of the reduced height that the fluke projects above ground when the lower one

Fig. 2.—Trotman's Anchor at Work.

has taken hold. The construction of the anchor is of course more complex than the ordinary solid anchor, and its peculiar form makes it somewhat awkward to 'fish,' and still more difficult to 'sweep,' in the event of the cable parting. On the other hand, it is very conveniently stowed on ship-board. In 1852 the Admiralty appointed a committee to make an elaborate trial of a large number of anchors; and that which obtained the highest place was Trotman's.

An anchor radically different is that patented by Martin, a Frenchman. It is self-canting, and both flukes are utilised at one operation for maintaining a hold of the ground. The arms, which are in one piece, are fitted through a hole in the crown end of the shank, which is increased in area for the purpose, and they are free to swing through a range of 30° relatively to the shank. Thus, on whatever side the anchor falls, the arms by their own weight and the pull of the cable are made to take hold of the ground at once. The stock, which is flat and broad, is fitted across the shank in the same direction as the arms. This anchor is simple in construction, being made in three separate forgings, without a weld, and is easily housed. The Admiralty—who favour this

Fig. 3.—Smith's Stockless Anchor.

anchor for special types of vessels—allow a reduction of 25 per cent. in weight; using an 80-cwt. Martin's anchor (with stock) where a 90-cwt. (with

stock, 108 to 112 cwt.) Admiralty or Rodgers' anchor would be fitted.

Several anchors which appear to be modifications of Martin's have recently been introduced. One of these being pretty extensively adopted is Wastenay Smith's stockless anchor (shown by fig. 3). Like Martin's, it is self-canting, and both flukes take hold of the ground at once, no matter how the anchor falls. The stock being dispensed with, a large saving in weight is effected.

A recent innovation, for which anchors of the type just described readily adapt themselves, is the formation of a recess in the ship's side at the mouth of the hawse-pipes, in which to house the anchors instead of hoisting them on deck—an arrangement which offers very considerable advantages over the ordinary system.

Till the introduction of the steam-hammer, anchor-making was the most formidable smith's work, on account of the great size and weight of the pieces of iron. The anchor-smiths wielded the most ponderous sledge-hammers known to our artisans. An even greater recent change is that crucible cast-steel is now taking the place of wrought-iron for anchors. At some of the government dockyards, anchor-making is conducted on a great scale; but the larger portion of the supply for the navy is obtained by contract with private firms.

Anchorage is a due or toll levied on the owner or captain of a ship for permission to cast anchor at special anchoring-grounds. In most instances it is payable to the state; but sometimes the right is vested in corporate bodies or in individuals. Anchorage also signifies 'anchor-ground,' the best ground being stiff clay, and, next to it, a firm sand.

Anchor-ice, or **GROUND-ICE**, a kind of ice which forms upon the beds of rivers, or shallow brackish seas. It only begins to form when the temperature of the atmosphere falls to within 10° F., and it does not adhere strongly to the bottom until zero is reached. It is somewhat porous or sponge-like in appearance, and when it rises to the surface, it frequently brings with it the stones or boulders to which it is attached. It is where the flow of the water is most interrupted and tumultuous that this kind of ice forms most readily; it seems not to form in perfectly still water, however clear. See ICE, and a work by BARNES (1907).

Anchorite. See HERMIT.

Ancho'vy (*Engraulis encrasicolus*), a small bony fish of the herring family (Clupeidae), of some importance as a food-luxury. It may attain a length of eight inches, but usually measures only about a finger's length. The snout of the pointed head projects considerably beyond the lower jaw, the abdomen and sides are covered with large silvery scales, the back has a greenish-blue colour, the tail is deeply forked. The species occurs

Anchovy.

abundantly round the European coasts, especially in the southern and Mediterranean region, while the genus is represented in all the warmer waters. It would seem to have been formerly more abundant in the British seas, as several acts of parliament in the reign of William and Mary regulated the anchovy fisheries. It seems, however, that the

fishery, rather than the supply of fish, has declined. In spring, shoals of anchovies leave the deep seas and approach the shore for spawning purposes. They are fished at night; attracted by lights, and captured by the seine net. They are salted, and used for sauces, &c. Three species are found in North American Atlantic waters, and four on the Pacific side. The Romans seem to have used them for the esteemed fish sauce called *garum*, and the Indian species (*E. brownii*) is used for making the condiment called Red Fish.

Anchovy Pear (*Grias cauliflora*), a tree belonging to a small genus somewhat doubtfully referred by Lindley to his order Baringtoniaceæ (now placed in Lecythidaceæ, or in Myrtaceæ). It grows in boggy places in the mountainous districts of Jamaica and other West Indian islands, attains a height of 50 feet, and has great oblong leaves 2 or 3 feet in length. The fruit is pickled and eaten like the East Indian mango, which it much resembles in taste.

Anchusa. See ALKANET.

Anchylosis. See ANKYLOSIS.

Ancillon, JOHN FREDERICK, a member of a French family which, after the revocation of the Edict of Nantes, migrated into Prussia, was born in Berlin, in 1767. Originally pastor of the French refugees, he was in 1792 appointed professor of History in the Military Academy of Berlin, and afterwards tutor to the crown-prince, having become known by his *Révolutions du Système Politique de l'Europe* (4 vols. 1803-5). In 1832 he became foreign minister, and died 19th April 1837.

Ancón, a modern watering-place and ancient burying ground in Peru, on the coast, 35 miles N.W. of Lima. For the mummies and other remains, see Reiss and Stübel (trans. by Keane, 1880-87).

Anco'na, capital of a province in Italy, is situated on a promontory of the Adriatic coast, 130 miles N.E. of Rome; pop. (1921) 66,291. Ancona province has an area of 750 sq. m.; pop. 334,654. The harbour, which had become silted up, has been greatly improved since 1887. It is now one of Italy's best harbours, one of the leading Adriatic ports, and an important naval station; and its commerce, which had declined, has revived. Imports (coal, coke, grain, chemicals, jute, fish, &c.) greatly exceed exports (silk waste and twist, asphalt, salted hides, calcium carbide, jute cloth, tartar, fruit, vegetables, sulphur). Ancona has shipbuilding yards and engineering works; and other local industries are indicated by its exports. Modern forts on the neighbouring heights have superseded the old citadel, long the city's only fortification. A mole of 2000 feet in length, built by the Emperor Trajan, and a triumphal arch of the same emperor, are the most notable monuments of antiquity. One of the most venerable buildings is the cathedral of San Ciriaco, built in the 11th century, and possessing the oldest cupola in Italy. In the old town the houses are in general mean, and the streets narrow. Ancona (which owes its name to its situation on an elbow-shaped promontory: Greek, *ἀγκών*, 'an elbow') is supposed to have been founded about 380 B.C. by Syracusans, who had fled from the tyranny of Dionysius the Elder. It was destroyed by the Goths, rebuilt by Narses, and again destroyed by the Saracens in the 10th century. It afterwards became a republic; but in 1532 Pope Clement VII. annexed it to the States of the Church. In 1797 it was taken by the French; but in 1799 General Meunier was obliged to surrender it to the Russians and Austrians, after a long and gallant defence. In 1832 a French force took possession of the town and kept it in their hands till 1838,

when both French and Austrians retired from the Papal States. In 1849 a revolutionary garrison in Ancona capitulated after enduring a siege by the Austrians of 25 days. In 1861 the flag of the kingdom of Italy waved over the ancient city.—*The March of Ancona* was the name applied to the territory lying between the Adriatic and the Apennines, from Tronto N.W. to San Marino. Erected into an independent marquisate under the Longobards, the district was a papal dependency from the 13th century, but passed into the hands of Victor-Emmanuel in 1860.

Ancre, BARON DE LUSSIGNY, MARSHAL D', originally Concino Concini, was a Florentine by birth, and came to the French court in 1600, in the train of Maria de' Medici, the wife of Henry IV. He married Leonore Galigai, one of the queen's women, and aided her in promoting the disagreement between the king and queen. After Henry's death, he became chief favourite and adviser of the queen-regent, and was raised to post after post of profit and honour, becoming at length marquis, and, in 1614, even marshal of France, though he had never seen war. His prodigality was immense, and he squandered enormous sums on the decoration of his palaces. Hated alike by nobility and populace, he was assassinated in the Louvre in open day, on the 24th of April 1617, the young king Louis XIII. himself being privy to the plot. His body was dragged by the mob through the streets, and burned before the statue of Henry IV. His wife was executed for having practised witchcraft to gain influence over the queen.

Ancren Riwe ('The Rule of the anchoresses') is the name of a famous Middle English religious work dating from the first quarter of the 13th century. It was a prose treatise written for the spiritual guidance of a little community of three religious women, Cistercian nuns, living at Tarente or Tarrant-Keynston on the Stour in Dorsetshire; and is interesting not merely as a monument of the current English of the period, but for its homely eloquence, its devoutness, its sensible hostility to needless austerities, and its sense of humour. The work, which consists of eight books, has been ascribed to Richard Poor (died in 1237 bishop of Durham), who was perhaps born at Tarrant, and certainly caused his heart to be buried here. Another account is that it was written by Simon of Ghent, bishop of Salisbury, for his own sisters, nuns at Tarrant.

The *Ancren Riwe* was edited for the Camden Society in 1853 by the Rev. J. Morton. A Latin Version also exists with the title *Regulae Inclusarum*.

Ancrem Moor, Roxburghshire, 5½ miles N.W. of Jedburgh, was in 1544 the scene of the defeat of 5000 English under Sir Ralph Evers and Sir Brian Latoun, by a Scottish force under the Earl of Angus and Scott of Buccleuch. A monument marks the spot where Lilliard, a Scottish maiden, is said to have done prodigies of valour.

Ancus Marcius. See ROME (*History*).

Ancyra. See ANGORA.

Andalu'sia (Span. *Andalucía*), a large and fertile region occupying the south of Spain. Its shores are washed both by the Mediterranean and the Atlantic; and, though it is not now a political division of Spain, it is more frequently spoken of than the eight modern provinces into which it has been divided. The name is a form of *Vandalistia* or *Vandalusia*, from the Vandals, who overran it in the 5th century. When it was a Phœnician trade-emporium, it was called Tartessus (probably the *Tarshish* of the Bible); the Romans named it Bætica, from the river Bætis, the modern Guadalquivir. In the 8th century, the Moors founded

here a splendid monarchy, which quickly attained a high degree of civilisation. The four great Moorish capitals were Seville, Córdoba, Jaén, and Granada. During the darkness of the middle ages, Córdoba was 'the Athens of the west, the seat of arts and sciences.' The Moorish kingdoms were finally conquered by the Castilians in 1235-48. Christian intolerance seriously and permanently impoverished the country; but later, under the Spaniards, painting arose in a new form in the schools of Velázquez and Murillo. Andalusia mainly consists of the great basin of the Guadalquivir, and the mountainous districts which bound it. In the south, the Sierra Nevada attains a height of 11,657 feet. Andalusia was called the garden and the granary of Spain; but now such names are merited only by portions of the country on both sides of the Guadalquivir, where, even with careless cultivation, the soil is luxuriantly productive, and vegetation generally assumes a tropical character. Cotton and sugar-cane flourish in the open air, and the cactus and aloe form impenetrable hedges. Wine and oil abound; but some tracts are very barren, especially in the west, owing to deficiency of water. On the whole, however, Andalusia is still one of the most fertile districts of Spain, owing to its delicious southern climate and the abundance of water supplied by its snowy mountains. Its breeds of horses and mules have long been celebrated. The mountains yield silver, copper, lead, iron, and coal; and some ores are extensively worked. The Andalusians are lively, imaginative, and active, but boastful, unwarlike, and superstitious. They speak a dialect of Spanish manifestly tintured with traces of Arabic. Andalusia is divided into the provinces of Almería, Jaén, Málaga, Cádiz, Huelva, Seville, Córdoba, and Granada. The chief towns are Seville, Córdoba, Jaén, and Cádiz (q.v.). Area, 34,300 sq. m.; pop. (1921) 4,257,139.

Andalusite, a mineral consisting of silicate of aluminium, occurs in slightly rhombic, four-sided prisms, and also in a massive form; pearl-gray or reddish in colour. It is met with not infrequently as a constituent of certain metamorphic rocks, as *Andalusite-schist*. A variety of andalusite is known as *chiastolite* (Gr. *chiastos*, 'decussated'). The crystals of this variety, when broken across, often show cruciform or tessellated patterns. They are common in certain altered argillaceous rocks.

Andamans, a group of thickly wooded islands towards the east side of the Bay of Bengal, about 680 miles S. of the Hugli, between 10° and 14° N. lat., and 92° and 94° E. long. They consist of the Great and Little Andaman groups, surrounded by many smaller islands. Great Andaman is more than 150 miles long and 20 miles broad, and comprises five islands, lying close together, the North, Middle, and South Andaman, Baratang, and Rutland Island. Little Andaman, which lies about 30 miles S. of the larger group, is 28 miles long by 17 miles broad. The total area is 2508 sq. m. The native inhabitants stand in the lowest stage of civilisation, and belong to the same family as the original small-statured races in southern India; their number in Great Andaman is about 700; in Little Andaman, about 600. Their religion is animistic. Those that have come into contact with the convicts have deteriorated morally. Their height seldom reaches five feet; their complexion is very dark, the hair crisp and woolly. The men go naked; the women wear round the loins a girdle of leaves. They have no settled dwellings, but go freely from island to island, and subsist on the fruits and beasts of the wood, and upon fish. A British settlement was made on North Andaman in 1789, but abandoned in 1796 for Penang. The capital of the present settlement is at Port Blair,

on South Andaman, the largest island of the group. The harbour here is one of the finest in the world. Since 1858, the Andamans have been a penal settlement for Indian convicts.

For the islands and their aboriginal 'Mincopies,' see books by Man (1883), Boden Kloss (1903), Sir R. Temple (1904), Mrs Talbot Clifton (*Pilgrims to the Isles of Penance*, 1912); and A. R. Brown (*Andaman Islanders*, 1922).

Andante (Italian), in Music, implies a movement somewhat slow and sedate, but in a gentle and soothing style. This term is often modified, both as to time and style, by the addition of other words—as *Andante affettuoso*, slow, but pathetically; *Andante cantabile*, slow, but in a singing style; *Andante con moto*, slow, but with emotion; *Andante grazioso*, slow, but gracefully; *Andante maestoso*, slow, with majesty; *Andante non troppo*, slow, but not too much so; *Andante pastorale*, slow, and with pastoral simplicity. See ADAGIO, SYMPHONY.—*Andantino*, properly somewhat slower, for many composers means a little faster than *Andante*.

Andelys, LES, a town in the Norman department of Eure, France, consisting of Great and Little Andely, situated less than a mile apart, and about 20 miles N.E. of Evreux. Great Andely has a Gothic church of the 13th century, with fine painted glass. Little Andely, close by the Seine, stands below the castle rock of Château Gaillard, a castle built by Richard Cœur de Lion to command the Seine, and taken and retaken during the old wars between England and France. Pop. 4000.

Andenne, a town of Belgium, 12 miles E. of Namur by rail, manufactures paper, porcelain, and tobacco-pipes, and has beds of pipe-clay and coal-mines in the neighbourhood; pop. 8000.

Anderab, or **INDERAB**, a town in Afghan Turkestan, on the northern slope of the Hindu Kush Mountains, 80 miles SSE. of Kunduz. It is an entrepôt of commerce between Persia and India. Pop. 6500.

Andermatt, or **URSERN**, a Swiss village in the canton of Uri, about 18 miles S. of the Lake of Lucerne. As it is at the crossing of the St Gothard road and that over the Furca Pass, it has long been famous both as a tourist centre, and for a considerable transit trade. The St Gothard railway does not touch the village.

Andernach, a little town belonging to the district of Coblenz on the Rhine, was once a Roman fortress styled *Antunnaeum*, then a residence of the Merovingian kings, and afterwards became one of the most flourishing places on the Rhine. The great tower on the north side, the fine old church—partly built in the Carolingian times—the old gate, the ruins of the great castle of the Archbishops of Cologne, and other relics of antiquity, give quite a medieval aspect to the town. It now contains about 7000 people, and is celebrated for its millstones, and for cement made of its tufa rock or trass.

Andersen, **HANS CHRISTIAN**, one of the great story-tellers of the world, the most widely popular of Danish authors, was born April 2, 1803, at Odense in Funen. The son of a poor shoemaker, after his father's death he worked for some time in a factory, but his wonderful singing and extraordinary talent soon procured him friends and patrons, of whom the earliest was Madame Bunkelund, widow of a poet of some reputation. He early displayed a talent for poetry, and was known in his native place as 'the comedy-writer.' Hoping to obtain an engagement in the theatre, he found his way to Copenhagen, but was rejected for his lack of education. He next tried to become a singer, but soon found that his physical qualities were quite unfitted for the stage. Generous friends,

however, helped him in his distress; and application having been made by one of them to the king, he was placed at an advanced school at the public expense, and so enabled to get the better of the defects of his education. Some of his poems, particularly the one entitled *The Dying Child*, had already been favourably received, and he now became better known by the publication of his *Walk to Amak*, a literary satire in the form of a humorous narrative. In 1830 he published the first collected volume of his *Poems*, and in 1831 a second, under the title of *Fantasies and Sketches*. Spite of his genius and industry he failed to please the critics, and his genial egotism made him an easy butt for their clumsy ridicule. A travelling pension granted him by the king in 1833 removed him from his miseries, and supplied what was needful for his mental development. Some of its fruits were his *Travelling Sketches* of a tour in the north of Germany; *Agnes and the Mermaid*, completed in Switzerland; and *The Improvisatore*, a series of scenes depicted in a glowing style, and full of poetic interest, inspired by the genial atmosphere of Rome and Naples. The public opinion, not of Denmark alone, but of Europe, asserted itself about the merits of the last of these books, and henceforth its author was safe from the critics. Soon afterwards, he produced *O.T.* (1836), a novel containing vivid pictures of northern scenery and manners, which was followed (1837) by another, entitled *Only a Fiddler*. In 1840 he produced a romantic drama entitled *The Mulatto*, which was well received; but another drama, *Raphaella*, was less successful. In the same year appeared his *Picture-book without Pictures*, a series of the finest imaginative sketches. In the end of 1840 he commenced a somewhat lengthened tour in Italy and the East, of which he gave an account in *A Poet's Bazaar* (1842). In 1844 Andersen visited the court of Denmark by special invitation, and in the following year he received an annuity. After that date he travelled much, visiting England as well as other countries. Among other works of Andersen are *The Story of My Life* (1855); *New Tales and Adventures* (1858-61); *Tales from Jutland* (1859); *The Sandhills of Jutland* (1860); *Tales for Children* (1861); *The Wild Swans*, and *The Ice Maiden* (1863).

His fame has long been more than European. His *Dying Child* has been translated into the language of Greenland; and on his seventieth birthday he was presented with a book containing one of his tales in fifteen languages. On the same occasion the king of Denmark gave him the Grand Cross of the Dannebrog Order. He died at Copenhagen, August 4, 1875. In his autobiography, Andersen has told the story of his life with all his peculiar charm. Most of his tales, moreover, were suggested by the incidents of his own life. Even his most fantastic stories have usually a background of actual experience, and perhaps to this is due, in no small degree, their most abiding charm—the perfectly naive and inimitable sense of reality and truth, even in incidents quite out of the world of the ordinary and the natural. His heavy face and ungraceful form hid a heart that overflowed with love for all lovely things; he secured himself the surest immortality in the heart of the children of the civilised world.

See, besides the egotistic *Story of my Life* (trans. 1871), his *Correspondence with the Grand-Duke of Saxe-Weimar* (trans. 1891) and the *Life* by R. Nisbet Bain (1895).

Anderson, ALEXANDER (1845-1909), a railway platelayer, born at Kirkconnel, Dumfriesshire, wrote *Songs of Labour* (1873), *Songs of the Rail* (1877), &c., and was librarian to Edinburgh University.

Anderson, ELIZABETH GARRETT (1836-1917), was born in London and brought up chiefly at Alde-

burgh, Suffolk. In 1860 she studied medicine with much credit at the Middlesex Hospital; but a petition from the students against the admission of women prevented her return. Miss Garrett met other obstacles, but in 1865 she passed the Apothecaries' Hall examination with credit, and in 1866 received her first dispensary appointment. In 1870 she was made a visiting physician to the East London Hospital, headed the poll for the London School Board, and was made M.D. by the university of Paris. In 1871 she married Mr Anderson (died 1907). 'She wrote on professional and social subjects, held many important professional posts, and in 1907 was made mayor of Aldeburgh, the first woman mayor in England. See WOMEN'S RIGHTS.

Anderson, JAMES, antiquary, was born at Edinburgh in 1662, and admitted a W.S. in 1691. In 1705 he published a treatise vindicating the independence of Scotland; thenceforward he was employed on his *Selectus Diplomatum et Numismatum Scotice Thesaurus*, which did not appear till 1739. He died in 1728.

Anderson, JAMES, a writer on political economy and agriculture, was born in 1739, at Hermiston, near Edinburgh; and while managing the family farm, he attended chemistry classes. He invented the small two-horse plough without wheels, commonly called the Scotch plough. When only twenty-four years of age, he rented a large farm in Aberdeenshire, where he wrote a series of essays upon agriculture; and in 1780, the university of Aberdeen bestowed on him the degree of LL.D. In Edinburgh he edited (1790-93) a periodical called *The Bee*; in 1797 he went to London, where he died in 1808. He greatly helped in promoting agriculture in Scotland; and in an essay in his *Recreations of Agriculture*, he anticipated some important principles subsequently advocated by Malthus and Ricardo, particularly the famous theory of rent.

Anderson, JOHN, founder of the college in Glasgow bearing his name, was born in the parish of Roseneath, Dumbartonshire, in 1726. He studied at the university of Glasgow, in which he was for four years professor of Oriental Languages; in 1760 he was transferred to the chair of Natural Philosophy. In addition to his usual class in physics, he instituted one for artisans, which he continued to teach to the end of his life. In 1786 appeared his *Institutes of Physics*, which went through five editions in ten years. He invented a species of gun, the recoil of which was stopped by the condensation of common air within the body of the carriage; but having in vain endeavoured to attract the attention of the British government to it, he went to Paris in 1791, and presented his model to the National Convention. It was hung up in their hall, with the following inscription over it: 'The gift of Science to Liberty.' Afterwards, when the allied monarchical forces had drawn a military cordon around the frontiers of France, Anderson ingeniously suggested the expedient, which was adopted, of making small balloons of paper, to which newspapers and manifestoes might be tied, and so carried to Germany. Anderson died in 1796, and by his will he directed that the whole of his effects, of every kind, should be devoted to the establishment of an educational institution in Glasgow, for the use of the un-academical classes.

ANDERSON'S COLLEGE was originally intended to be a university of four colleges. The funds being inadequate to the proposed plan, the institution was opened with only a single course of lectures on Natural Philosophy and Chemistry, by Dr Thomas Garnett in 1796. In 1798 a professor of Mathematics and Geography was appointed. In 1799

Dr Birkbeck, the successor of Dr Garnett, commenced the system of giving a familiar exposition of mechanics and general science, and this was the origin of mechanics' institutes.

In 1861-1870 the endowments were augmented by Freeland, Ewing, and Young. The institution gradually enlarged its sphere of instruction, till it came to have a staff of nearly twenty professors and lecturers. Instruction was given in Mathematics, Latin, Greek, Hebrew, French, &c., afterwards limited to medicine, physics, chemistry, and botany. In 1886 the non-medical school was incorporated with five other institutions as the Glasgow and West of Scotland Technical College (since 1912 the Royal Technical College), of whose new buildings the memorial stone was laid in 1903.

Anderson, MARY, a distinguished actress, was born at Sacramento, California, July 28, 1859, of Catholic parentage, her father being a Confederate officer who lost his life in the civil war. She played for the first time at Louisville, in 1875, in the character of Juliet. Her success was marked and immediate, and during the following years she played with increasing popularity in the principal cities of the Union in various rôles. In 1883 she appeared at the Lyceum Theatre in London, and became a favourite in England. In 1890 she married M. Navarro de Viana of New York.

Andersonville, a village in Georgia, U.S., noted as having been the seat of a Confederate States military prison, which was notorious for unhealthfulness and for barbarity of discipline. Between February 15, 1864, and April 1865, 49,485 prisoners were received, of whom 12,926 died in that time of various diseases. Henry Wirz, the superintendent, was tried for injuring the health and destroying the lives of the soldiers confined here, was found guilty, and hanged, November 10, 1865. The long trenches where the soldiers were buried have since been laid out as a cemetery.

Andersson, KARL JOHAN, an African explorer, born in Sweden, in the province of Weimland, in 1827. In 1850 he joined Francis Galton in a journey to the territories of the Damaras and Ovampos, and in 1853-54 continued the exploration alone, publishing, on his return to England, *Lake Ngami, or Discoveries in South Africa* (Lond. 1856). In 1858 he explored the Okavango (*The Okavango River*, Lond. 1861), and in 1866 he set out, almost unattended, on an expedition to the Cunene. He came within sight of the stream, but, weakened with dysentery, had to retrace his steps, and died on the homeward journey, July 5, 1867.

Andes, a lofty mountain-system of South America, extending north and south closely parallel with the Pacific coast of that continent, throughout its whole extent, from lat. 56° 30' S. to 11° N. Geographically, it may be regarded as an extension of the vast and complicated mountain-system of Western North America, although it is not distinctly connected with that system. As the Andean chain approaches the Isthmus of Darien, after having crossed the Atrato, it is represented by a low crest of serpentine, at one point only 180 feet high; and much of the Isthmus proper is even lower than that.

The mountains of the Fuegian Archipelago, south of the mainland of South America, must be held to belong to this system. Cape Horn, on a detached island, is regarded as the most southerly point of the chain, which, however, may be said to extend to the rocky islets of Diego Ramirez, 60 miles SW. of the Cape. Without allowing for curves, the Andes extend some 4500 English miles. For about 1000 miles (south of Chiloe), the mountains not only reach the ocean, but in part stand in its waters, for the great Chonos Archipelago is only

an irregular double chain of mountains. Indeed some geographers hold that these islands for at least 300 miles north of Cape Horn, in reality represent the main chain of the Andes. The Patagonian portion of the system is much cut by steep ravines, sometimes partly filled with glaciers, and not seldom occupied by deep fjords, or arms of the sea. On the eastern slope in Patagonia lie vast masses of granite, porphyry, basalt, and lava; and on both sides of the ranges vegetation is luxuriant; extensive forests covering a large proportion of the surface. This is chiefly due to the excessive abundance of the rainfall, to which cause also must be ascribed the numerous and rather large sub-Andean lakes of Patagonia, and the swift and copious streams which water its wild and gloomy terraces—for the ascent to the mountains is here by a step-like succession of steep rises. The Patagonian Andes cover a strip of land from 20 to 50 miles in breadth, and, as will be seen in the table given below, are not of great height.

Between lat. 42° and 24° S. the main chain of the Andes recedes from the sea-coast, leaving in Chile a tract of country nowhere exceeding 120 geographical miles in breadth. The mountains here reach a mean elevation of 11,830 feet; one of the peaks (Aconcagua) is the loftiest on the American continent. In this region, both to the north and to the south, there is but one main line of peaks; but between these two parts two high parallel ranges occur, having between them a relatively low plateau. A low parallel ridge of granite skirts the mountains to seaward. On the Argentine side a great number of buttress-like processes extend into the Pampas country, chiefly having a south-easterly direction, except to the northward, where they are numerous, and are nearly parallel with the main Andes. The Bolivian Andes occupy perhaps one-third of the area of the republic. They form a vast arid region of great elevation. The east and west Cordilleras of Bolivia inclose the land-locked plateau of the Desaguadero, 13,000 feet in height, and having an area of 30,000 sq. m. It has thus about the superficial extent of Ireland, and has been called 'the navel of South America.' In the vicinity are several much smaller land-locked basins of similar character; and near at hand are some of the loftiest of the Andean summits.

The Peruvian Andes present features of great interest. The maritime Cordillera overlooks the sea in a close succession of volcanic cones. Near lat. 10° S. the chain divides into the seaward Cordillera Negra, and the more eastward Cordillera Nevada, with a deep trough or ravine intervening. The central Cordillera of Peru is the chain which bounds the Titicaca basin on the west. No river, except the Marañon (Upper Amazon), cuts through its vast wall-like ridges. The eastern Andes of Peru lie between a high, cool, western valley and the hot and seething forest plains of the Amazonian basin. They form a magnificent succession of grand peaks, with only very local evidences of recent volcanic action. To the north they decline greatly in elevation. Here the grandest scenery of the Andes is to be witnessed. The lofty wildernesses of the high Peruvian Andes form a cold and wind-swept region known as the Puna, and are scarcely habitable. In the SW. of Ecuador the various ridges of the Andes coalesce, immediately to divide again into two main chains, both characterised by intense volcanic activity. Transverse ridges divide the intervening valley into three basins, that of Cuenca in the south, Ambato in the centre, and Quito (with its fine climate and productive soil) in the north. The Cuenca basin is 7800 feet in elevation, that of Ambato 8500, and that of Quito 9500 feet.

The Colombian Andes are disposed in three main lines. The maritime range runs north and ends at Cape Tiburon, on the coast of the Caribbean Sea. It declines greatly in height to the northward, and the same thing is true of the central range, which in the south, near the great *paramo* or tableland of Cruz Verde, are very lofty. The very lofty eastern range (Cordillera of Suma Paz) extends to the N.E., and near the Venezuelan boundary it forks out into two chains, one of which forms the Goajira peninsula west of Lake Maracaibo, and the other becomes the main Venezuelan mountain-system. Near Caracas the mountains skirt the sea-coast. Only a few of the peaks of the Venezuelan Andes rise above the snow-line.

PLATEAUS

Of the numerous plateaus of the Andes system, one, Assuay, is at a height of 14,500 feet. That of Titicaca, the Collao, is 12,500 feet; of Cruz Verde, 11,695 feet; of Pasco, 11,000 feet; of Quito, 9500 feet; of Bogota, 8968 feet.

PASSES.

Of nine notable Chilean passes, the lowest (Planchón) is 11,455 feet high, the highest (Dona Ana), 14,770 feet. In the Bolivian Andes the passes of Potosí and Gualillos are respectively 14,320 and 14,880 feet. Of Peruvian passes, Jacaibamba is 15,135 feet, and Antarunga, 16,196 feet high, while Assuay, in the Ecuadorian Andes, is 12,385 feet; and Quindío, in the Colombian Andes, is 11,500 feet high.

Geologically, the Andes are by no means a unity. It is certain that the elevation of the different parts must have occurred at various times. The great bulk of the mountain masses is composed of stratified rocks, largely made up of materials which were deposited at the sea-bottom. It is believed that as a whole the formative sediment must have accumulated on subsiding areas. Upheaval, denudation, and direct volcanic action have been the other leading factors in the building and shaping of the mountains. The mineral wealth is great and varied. Volcanic action is still very active in Ecuador, but less so in the other parts of the chain. The Chilean volcanoes are numerous, but are seldom very active. Earthquakes occur frequently all along the coast from Caracas to Chiloe. Gold, silver, copper, mercury, and other metals are found in most parts of the Andes; see PERU, &c. Railway connection between the Atlantic and Pacific, between Buenos Aires and Valparaíso, through the Andes was established in 1910 by means of a series of tunnels in the La Cumbre pass, 12,600 feet high, one of them 10,000 feet long. There are other railways through the Andes in Peru, from Chile into Bolivia, and one from Copiapó in Chile into Argentina is planned. For the effect of the Andes on the climate of the Pacific slope, see AMERICA. The awful cañons and chasms of the Andes, the sublime height of their peaks, the difficult and dangerous character of the passes, are characteristic features.

Andesine. See FELSPAR.

Andesite, a group of volcanic rocks, gray, reddish, or dark brown in colour. They consist essentially of plagioclase-felspar and some ferromagnesian mineral, as biotite, augite, hornblende, or hypersthene; the ground-mass is microlithic, scattered through which plagioclase and ferromagnesian

minerals may appear as more or less conspicuous phenocrysts.

Andijan, in Ferghana, near the Alai Mountains, on the Syr-Daria, 75 miles ENE. of Khokand, is the terminus of the Transcaspian Railway. There is much cotton culture, promoted by irrigation; and although almost wholly destroyed by an earthquake in December 1902, the town has greatly increased in recent years. Pop. 77,000.

Andira, a genus of papilionaceous plants, one of which, the *A. inermis* or Cabbage Tree, produces the anthelmintic Cabbage Bark.

Andirons, now more generally known as fire-dogs, were used for burning wood on an open hearth, and consisted of a horizontal bar raised on short supports, with an upright standard at one end. A pair were used, one standing at each side of the hearth, and the logs of wood rested across the horizontal bars. The upright portions of the andirons were of various forms; the design was frequently architectural, much ornamented with arabesques in silver or copper, and sometimes with the monograms of their possessors. Those for kitchen use had catches for holding the roasting apparatus.

Andiron.

Andkhui, a town and khanate in Afghan Turkestan. The town stands between the northern spurs of the Paropamisus and the Amu Daria (Oxus); it is due west of Balkh and on the edge of the desert. Down to the year 1840, it was subject to Bokhara. In that year, Mohammed Khan besieged it for four months, took it by storm, and left it a heap of ruins. To preserve himself from utter destruction, the khan threw himself into the arms of the Afghans. The tract in which it stands is fertile, but the place is proverbially unhealthy; the Persians account it 'a hell upon earth,' by reason of its scorching sands, brackish water, flies, and scorpions. The population is estimated at 15,000, consisting principally of Turkomans, with a mixture of Uzbegs and a few Tajiks. The khanate, though controlled by Kabul, has preserved some measure of independence.

Andorra, a small, semi-independent, neutral state, on the southern slope of the Eastern Pyrenees, between the French department of Ariège and the Spanish province of Lérida. Roughly circular in shape (with a diameter of some 15 miles), Andorra is enclosed and covered by mountains, rising to 9000 feet and penetrated by the Valira (or Balira) and subordinate valleys. The population, at one time estimated at 15,000, scarcely exceeds 5200. The area of Los Valles, as the Andorrans call their country, is 175 sq. m., divided into six parishes. The climate is severe. Once abundant forests have been much thinned for fuel; there is excellent pasture for flocks and herds; cereals, fruit-trees, vines, and tobacco grow on the lower grounds; and the mountains contain iron and lead mines, granite, water-power, and mineral springs all of which await exploitation. The smuggling into France of tobacco (Andorra's only noteworthy manufacture) is actively carried on. Andorra is said to have been declared a free state by Charlemagne. The joint-suzerainty of the bishops of Urgel and the counts of Foix was defined in 1278. The counts' rights passed to the kings of Navarre, and so to France. Thanks to Franco-Spanish rivalry and its inaccessibility, Andorra has preserved its medieval autonomy. It

is governed by a council of twenty-four (elected by the heads of households), who choose a *syndic* (president) and vice-syndic. There are two criminal judges called *viguers* (vicars), one appointed by France, one by the Bishop of Urgel; also a civil judge appointed by the suzerains alternately. Annual tributes of 960 and 460 francs are paid to France and the bishop respectively. Since 1882 French interests are represented by the Prefect of Pyrénées Orientales. Andorra communicates with Urgel in Spain by the Valira valley; with France by the Emballira Pass (7500 feet). Carriage-roads are beginning to replace mule-paths; the French have introduced telegraphs; and the Trans-Pyrenean Railway from Ax to Ripoll will further abate the isolation of Andorra. The Andorians are good-natured, hard-working mountaineers, Catalan in stock and speech, devout Roman Catholics. They cling jealously to their freedom (especially from military service). The capital is Andorra la Vieja (pop. 500).

See Harold Spender, *Through the High Pyrenees* (1898); L. G. Leary, *Andorra, the Hidden Republic* (1912); and Scott O'Connor, *Travels in the Pyrenees* (1913).

Andover, a municipal borough and market town of Hampshire, 66 miles SW. of London. Originally *Andeafuran* (passage of the river Ande), Andover dates from a remote antiquity, and received charters from Henry I., Richard I., and John. Till 1867 it returned two members to parliament; till 1885, one. The chief trade of Andover consists in corn and malt; there used to be manufactures of shallons. At Weyhill, 3 miles to the west, an October fair is held, formerly one of the most important in England. The church of Andover, rebuilt in 1849, is in the Early English style. A Roman villa and other relics of antiquity have been discovered near Andover. Population, 8600.

Andover, a village of Essex county, Massachusetts, 23 miles N. of Boston. Settled in 1643 from its English namesake, it is famous, even in Massachusetts, for its educational institutions. The Phillips Academy, instituted in 1780, is liberally constituted and well attended. The Andover Theological Seminary of the Congregationalists, an offshoot from it, was founded in 1807, for the purpose 'of providing for the church a learned, orthodox, and pious ministry.' Largely endowed, it offers free residence and instruction, and is frequented by students of various denominations. There is a valuable library of 30,000 volumes, and the *Bibliotheca Sacra*, a quarterly edited by the professors, is one of the leading theological organs of New England. The Abbot Female Academy, for the education of female teachers, and the Punchard High School, are also flourishing institutions. Pop. 8300.

Andral, GABRIEL, a celebrated French physician and pathologist, born at Paris, 6th November 1797. In 1827 he was called to the chair of Hygiene, in 1830 to that of Pathology, in the university of Paris. He died February 13, 1876. Andral may be said to have been the first to apply an analytical and inductive method to pathology. His *Clinique Médicale* (1824) established his reputation, and his *Précis d'Anatomie Pathologique* (1829) was equally successful. Other works of importance are his *Essai d'Hématologie Pathologique* (1843); *Cours de Pathologie Interne*; and *Recherches sur les Modifications de Proportion de quelques Principes du Sang*.

Andrassy, JULIUS, COUNT, a Hungarian statesman, was born at Zemplin, March 8, 1823. He was returned by his native town to the Presburg Diet of 1847, where he soon displayed oratorical and political powers of no mean order.

He threw himself heartily into the revolutionary movement of 1848, and on its defeat was exiled, retiring to France and England, until the general amnesty of 1857 enabled him to return to his own country. He was elected a member of the Hungarian Diet in 1860, where his support of the Deak party secured him the office of vice-president; and, on the reorganisation of the Austro-Hungarian monarchy in 1867, he was appointed prime-minister of Hungary. The chief event of his administration was the civil and political emancipation of the Jews. In 1871 Count Andrassy became minister for foreign affairs, and in 1878 ably represented Austria at the Congress of Berlin. In 1879 he retired from public life, and died 18th February 1890.

André, JOHN, an accomplished British officer during the American Revolutionary War, is chiefly remembered for his connection with the treason of the colonial general, Benedict Arnold (q.v.), and was born in London in 1751. His father was a merchant from Geneva, and his mother (*mée* Girardot), though a native of London, was of French descent. Young André distinguished himself at the university of Geneva; but, on his father's death in 1769, he returned to London and assumed the management of the business. Finding mercantile pursuits irksome, however, he procured a commission, and in 1774 joined his regiment, the Royal Fusiliers, in Canada. He was captured at St John's by the colonial forces, was exchanged the following year, and became aide-de-camp successively to General Grey and Sir Henry Clinton, receiving from the latter (in 1780) the appointment of adjutant-general, with the rank of major.

During the occupancy of Philadelphia by the British army under General Howe in 1777-78, André was a welcome guest in the most aristocratic circles of that city, and was a recognised leader in their social festivities. He appears to have been particularly intimate in the family of Mr Edward Shippen, whose favourite daughter afterwards became the wife of General Benedict Arnold, and when in 1780 the latter obtained the command of West Point, André was selected by Clinton to consummate the arrangements with Arnold for the betrayal of that post. A meeting between the conspirators was agreed upon, and on the night of September 20, 1780, Major André embarked on board the sloop of war *l'ulture*, and proceeded to the rendezvous, some 35 miles up the Hudson, near the hamlet of Haverstraw. The place of meeting was on neutral ground in a thicket near the bank of the river, and thither at midnight, after remaining on board the sloop all day, André was conducted by a trusty friend of Arnold, one Joshua H. Smith, a resident of the vicinity, to whom the object of the meeting was known. Failing to finish their business during the night, they repaired in the morning to Smith's house, within the American lines, whence, at the termination of their interview, Arnold departed for his headquarters, having first furnished André with a pass through the American lines (as Mr John Anderson), and papers containing the plan for the surrender of West Point. The fatal mistake of accepting and retaining these papers on his person was in direct disobedience to Clinton's instructions. Concealing the papers in his stockings, André, accompanied by Smith and a negro servant, set out on his return to New York; but Smith, fearing to attempt to get him on board the *Vulture*, decided that the journey must be made by land. They crossed the Hudson at King's Ferry, spent the night within the American lines, and parted in the morning, Smith to return home, and André, mounted on a horse, to pursue his dangerous journey alone. As André neared the British lines, he was halted by an armed band. He declared

himself a British officer on important business, and demanded permission to proceed. To his consternation his captors (one of whom wore a Hessian coat) proved to be ardent partisans of the colonists, and although AndrĚ finally produced the pass given him by Arnold, their suspicions were so thoroughly aroused that they conducted him back within the American lines and delivered him to the military authorities.

The papers found upon his person clearly established his character as a spy, and a military board convened by Washington declared that 'agreeably to the laws and usages of nations he ought to suffer death.' Washington approved the finding of the board, and AndrĚ was sentenced to be hanged. At the earnest solicitation of the British commander, the execution was stayed for a day on the plea that the board 'had not been rightly informed of all the circumstances;' but at an informal meeting with the president of the board he failed to adduce any sufficient reason for a commutation of the sentence, and AndrĚ was accordingly hanged at Tappan-town, 2d October 1780. He was buried near the place of execution. A monument to him was erected in Westminster Abbey by order of the king, and thither his remains were brought in 1821.

See his *Life* by Winthrop Sargent (1861; new ed. 1902); his *Journal* (1904); Trevelyan, *George III. and Charles Fox* (vol. i. 1912); books by Joshua H. Smith (1808) and Benson (1817); the *Lives* of Benedict Arnold (q.v.); Lossing, *The Two Spies* (1886).

AndrĚĀ, JOHANN VALENTIN, born in 1586 near Tübingen, became a Protestant pastor, and died in 1654 at Stuttgart, where he was chaplain to the court. His writings are remarkable for wit and humour, acuteness and moral power. He was long regarded as the founder or restorer of the order of the Rosicrucians (q.v.), a view based on his misunderstood *Chymische Hochzeit Christiani Rosenkreuz* (1616)—really meant to ridicule the follies of the age, Rosicrucianism included. He wrote mainly in Latin, but also in the Swabian dialect. Among his works are his *Menippus* (1617) and his *Geistliche Kurzweil* (1619).

Andrea del Sarto. See SARTO.

Andree, SALOMON AUGUST, Swedish engineer, born in 1854, was examiner to the Patents Office when in 1897 he undertook a balloon voyage to the North Pole, and was never again heard of.

AndrĚĕff (or ANDREYEV), LEONID (1871-1919), born at Orel, suffered much from poverty, hunger, and ill-health at the universities of St Petersburg and Moscow, and after attempted suicide in 1894 began to write and paint portraits. In 1897 he was called to the bar, but practised little. His stories and dramas (a number of them translated), which rank him high in Russian literature, include *Red Laughter*, *The Life of Man*, *To the Stars*, *Vasily Fvetsky*, *Eliazar*, *Black Masks*, *The Seven who were Hanged*, and *Judas Iscariot*.

AndrĚossy, ANTOINE FRANÇOIS, COUNT (1761-1828), was born at Castelnaudary, in Languedoc. He served under Bonaparte in Italy and Egypt and on the 18th Brumaire, and was ambassador at London, at Vienna, and at Constantinople, whence he was recalled at the Restoration. He was raised to the peerage by Napoleon after his return from Elba. After the battle of Waterloo, he advocated the recall of the Bourbons; but as deputy he generally took part with the opposition. He died at Montauban. He was a man of eminent scientific attainments, one of his earliest works being the *Histoire Générale du Canal du Midi*. Besides his scientific works, he wrote several military *Mémoires*.

Andrew, the first disciple, and one of the apostles of Jesus. His career after the Master's death is unknown. Tradition tells us that, after

preaching the gospel in Scythia, Northern Greece, and Epirus, he suffered martyrdom on the cross at PatrĀ in Achaia, 62 or 70 A.D. The anniversary of *St Andrew* falls on November 30. About 740 *St Andrew* became the patron saint of Scotland (see the article *ST ANDREWS*); and he is held in great veneration in Russia, as the apostle who, according to tradition, first preached the gospel in that country.

CROSS OF ST ANDREW.—A white saltire on a blue ground, to represent the x-shaped cross on which the patron saint of Scotland suffered martyrdom, has been from an early date adopted as the national banner of Scotland. It is combined with the crosses of *St George* and *St Patrick* in the Union Jack (q.v.). The Scottish Order of the Thistle (q.v.) is sometimes known as the Order of *St Andrew*.

THE RUSSIAN ORDER OF ST ANDREW was the highest in the empire, and was founded by Peter the Great in 1698. It had but one class, and was confined to members of the imperial family, princes, and persons of the rank of general who already held two other important orders. The badge of the order shows on the obverse the double-headed eagle, crowned, on which is a *St Andrew's Cross* enamelled in blue, with a figure of the saint.

Andrew, JOHN ALBION, an American statesman, was born at Windham, Maine, in 1818, studied law, and was admitted to the bar at Boston in 1840. Distinguished for his opposition to slavery, he was elected a member of legislature by the republicans of Boston in 1858; in 1860 he became governor of Massachusetts, and was four times re-elected, retiring in 1866. He acquired great popularity by his attention to the wants of the soldiers in the field, for his fervid eloquence and patriotism during the war, and his zeal for the liberation and the arming of the negroes. He died October 1867.

Andrewes, LANGELOT, was born at All Hallows Barking, in London, in 1555, and educated successively at the Coopers' Free School in Ratcliffe, at Merchant Taylors' School, and at Pembroke Hall, Cambridge, of which college he was in 1576 elected fellow. Taking orders in 1580, he accompanied the Earl of Huntingdon to the north; and in 1589, through Walsingham's influence, he was appointed a prebendary of St Paul's and Master of Pembroke Hall. In 1597 Elizabeth made him a prebendary, and in 1601 dean, of Westminster. He rose still higher in favour with King James, who was well qualified to appreciate his extensive learning and peculiar style of oratory. He attended the Hampton Court conference, as one of the ecclesiastical commissioners, and took part in the translation of the Bible. In 1605 he was consecrated Bishop of Chichester; in 1609 he was translated to Ely, and appointed a privy-councillor, both for England and Scotland. To the latter country he accompanied the king in 1617, as one of the royal instruments for persuading the Scots of the superiority of episcopacy over presbytery. In the following year he was translated to Winchester; and he died 25th September 1626. A zealous High Churchman, Andrewes was, with the exception of Usher, the most learned English theologian of his time. As a preacher, he was regarded by his contemporaries as unrivalled; but the excellent qualities of his discourses are apt to suffer much depreciation in modern judgment from the extremely artificial and frigid character of the style. His principal works published during his life were two treatises in reply to Cardinal Bellarmine, in defence of the right of princes over ecclesiastical assemblies.

These, with sermons and manuals of devotion, fill 8 vols. of the *Library of Anglo-Catholic Theology* (1841-54). See *Lives* of him by A. T. Russell (1863), R. L. Ottley (1894), and D. Maclean (1910).

Andrews, THOMAS, physicist, was born in Belfast, 19th December 1813, and studied chemistry and medicine at Glasgow, Paris, Edinburgh, and Dublin. He practised as a physician at Belfast, where in 1849 he was appointed professor of chemistry in the Queen's College. F.R.S. and LL.D., he resigned his chair in 1879, and died 26th November 1885. His brilliant researches were more of a physical than of a chemical nature, being on the heat of combination of various classes of substances, on the nature of ozone, on the conducting power for heat of the various gases, and on the continuity of the liquid and gaseous states of matter. See his *Scientific Papers*, edited, with a memoir, by Profs. Tait and Crum Brown (1889).

Andria is a city of South Italy, 30 miles W. of Bari, with a fine cathedral (1046; burned in 1916), and a trade in almonds. Pop. 59,000.

Andrieux, FRANÇOIS GUILLAUME JEAN STANISLAS, a French scholar and dramatist, born at Strasburg, May 6, 1759. He began life as an advocate and promising politician, but his political career was cut short by Bonaparte, and he turned to literature as a calling. On the restoration in 1814, he was appointed to a chair in the Collège de France, was admitted to the Academy two years later, and made perpetual secretary in 1829. He died May 10, 1833. Of his many comedies, the best are *Les Étourdis* (1788) and *La Comédienne* (1816). He wrote also a tragedy, *Junius Brutus*, and numerous poems, full of grace and spirit, in the form of fables, tales, romances, and epistles.

Androclus, a Roman slave of the early part of the 1st century, the hero of a well-known story related by Aulus Gellius. Having attempted to run away from his master, he was sentenced to be torn by wild beasts in the circus, but to the amazement of the spectators, the lion when let loose rushed up to him and began to lick him fondly. On inquiry it was found that he had once pulled a thorn out of a lion's foot in a cave in Africa, and that the grateful beast had at once recognised in him his benefactor. Androclus was pardoned by the emperor, and afterwards led the lion about the streets of Rome.

Androgynous (Gr., 'male-female'), an almost obsolete term applied (1) to plants where the inflorescence is *monœcious*—i.e. consists of distinct male and female flowers; and (2) to animals which are *hermaphrodite*—i.e. possess a distinct male and female generative system in the same individual. This is the case with very many of the lower animals, but is not inconsistent with a necessity for the co-operation of two individuals in the propagation of the species. See REPRODUCTION, HERMAPHRODITISM.

Andromache, the wife of Hector, was the daughter of Eëtion, king of the Cilician Thebes, and is one of the finest female figures in Homer's *Iliad*. During her childhood, Achilles slew her father and her seven brothers. By Hector she had a son, Scamandrius (Astyanax). Her love of her husband is pathetically depicted in her address to the hero on his going to his last battle, and her lamentation over his death. After the fall of Troy, she was given into the hands of Pyrrhus (son of Achilles), who took her away to Epirus, but afterwards surrendered her to Helenus (Hector's brother), by whom she had a son named Cestrinus. Andromache is the heroine of one of the tragedies of Euripides.

Androm'eda, daughter of the Ethiopian king Cepheus and Cassiopeia, like her mother, remarkable for her beauty. Cassiopeia having been rash enough to boast that her daughter was more

beautiful than the Nereids, these offended deities prayed Poseidon (Neptune) to revenge the insult. Accordingly, the territory of King Cepheus was devastated by a flood; and a terrible sea-monster appeared, whose wrath the oracle of Ammon declared could only be appeased by the sacrifice of Andromeda. She was fastened to a rock, and left as a prey to the monster, when Perseus, returning from his victorious battle with Medusa, saw the beautiful victim, and determined to rescue and win her. Having slain the sea-monster, he received Andromeda as his reward. Athena gave Andromeda a place among the constellations. Her story is told in fine English hexameters by Charles Kingsley.

Andromeda, a genus of the Ericaceæ. See HEATH.

Andron'icus OF RHODES, a Peripatetic philosopher, lived at Rome in Cicero's time, and employed himself in criticising and explaining the works of Aristotle, a great number of which he was probably the means of preserving to us. None of the writings of Andronicus himself are extant. He must not be confounded with another Greek and Aristotelian, *Andronicus Callistos*, professor in Italy in the 15th century.

Andron'icus, the name of four Byzantine emperors.—Andronicus I., Comnenus, grandson of Alexius I., was one of the most conspicuous characters of his age, which produced no man more brave, more profligate, or more perfidious. In his youth he served against the Turks, in 1141 was for some time a prisoner, and was afterwards appointed to a military command in Cilicia, but was unsuccessful. Having engaged in a treasonable correspondence with the King of Hungary, he was thrown into prison by his cousin, the Emperor Manuel; but after twelve years he succeeded in making his escape, and reached Kiev, the residence of Prince Jaroslav. He regained the favour of his cousin by persuading Jaroslav to join him in the invasion of Hungary, and by his gallantry in that war; but soon incurred his displeasure again, and was sent in honourable banishment to Cilicia. After a pilgrimage to Jerusalem, and his scandalous seduction of Theodora, the widow of Baldwin, king of Jerusalem, he settled among the Turks in Asia Minor, with a band of outlaws, making frequent inroads into the province of Trebizond; but at length made his peace with the emperor, and was sent to Cœne in Pontus. After the death of Manuel in 1182, he was recalled to become, first guardian, then colleague, of the young Emperor Alexius II. Soon after, he caused the empress-mother to be strangled, and afterwards Alexius himself, with whose youthful widow he contracted an indecent marriage. His reign, though short, was vigorous, and restored prosperity to the provinces; but tyranny and murder were its characteristics in the capital. At last, a destined victim, Isaac Angelus, one of his relatives, having fled to the Church of St Sophia for sanctuary, a crowd gathered, and a sudden insurrection placed Isaac on the throne, whilst Andronicus, now 73 years of age, was put to death by the infuriated populace, after horrible mutilations and tortures, on September 12, 1185.—For other monarchs of the name, see BYZANTINE EMPIRE.

Andronicus, LIVIUS. See LIVIUS ANDRONICUS.

Andropo'gon. See GRASS-OIL.

Andros, an island of the Greek Archipelago, the most northern of the Cyclades, separated from Eubœa by a channel, the Doro Channel, 6 miles broad. The island is 25 miles long, and about 10 miles in its greatest breadth, the area being 156

sq. m. Its eastern coast is very irregular. It is mountainous, and on some of its mountains snow lies during great part of the year. The soil is remarkably fertile, and wine, silk, olives, and lemons are produced. The population is about 18,000. The chief town, Andros, is situated on a bay of the eastern coast. It has a little harbour, and about 2000 inhabitants.—ANDROS is also the name of one of the Bahamas (q.v.).

Andújar, a town of Andalusia, Spain, in the province of Jaén, on the right bank of the Guadalquivir, at the base of the Sierra Morena, 48 miles ENE. of Córdoba by rail. The river is crossed by a bridge of seventeen arches. The town is noted for the manufacture of porous cooling clay water-vessels. The Convention of Bailén was signed here on 23d July 1808. Pop. 17,000.

Anecdote (Gr. *an-*, 'not,' and *ekdotos*, 'published'), a narrative of any single incident or fact of an interesting nature. The term in earlier times meant only private or hitherto unpublished narratives or details of history, from its use by Procopius, by whom it was applied to his '*Unpublished Memoirs*' of the Emperor Justinian, consisting chiefly of tales of the private life of the court.

Anegáda, the most northerly of the Virgin Islands, lying east of Porto Rico in the West Indies. It contains about 13 sq. m., with a scanty population of 200, and belongs to England. A little cotton is grown. The island is of coral formation, and beset with reefs; shipwrecks are now rare, thanks to the lighthouse on Sombriero.

Aneteum. See NEW HEBRIDES.

Aneling is literally anointing (O.E. *an*, 'on,' *elien*, 'to oil,' from *ele*, 'oil,' Lat. *oleum*); in particular Extreme Unction (q.v.).

Anemometer (Gr. *anemos*, 'the wind,' *metron*, 'a measure'), an instrument for measuring the pressure or velocity of the wind. The simplest

Robinson's Hemispherical-cup Anemometer.

anemometer is that which is generally known as Robinson's hemispherical-cup anemometer (see fig.), invented by Dr Robinson of Armagh in 1846. It consists of four hemispherical cups fixed to the ends of two crossed metal arms and supported on a vertical axis which turns freely. The number of revolutions of the cups in a given time is proportional to the amount of wind which passes them. Careful experiments have shown that the ratio of the distance travelled by the wind to the distance travelled by the cups, instead of being indicated by 3, as used to be thought, varies between 2.2 and 2.8 according to the size of the cups and length of the arms. This is allowed for in the system of gearing, whereby the number of miles travelled by the wind is shown on a dial or series of dials.

Pressure anemometers are of very great importance in meteorological observatories and for engineering purposes. Of these, one of the best known is that invented by Osler. In this instrument, the force of the wind is ascertained by means of a brass plate one foot square which is suspended by springs, and being attached to the vane of the instrument, is maintained at right angles to the direction of the wind. This plate, by the action of the wind, is beaten back upon the springs, and in so doing, causes a pencil to move backwards and forwards on a sheet of paper placed below it. This sheet of paper is made to pass under the pencil in a direction at right angles to its oscillation; and by means of clockwork, moves at a uniform rate, so that the force of the wind at any particular time of the day is recorded. A pencil in connection with

Register-sheet of an Osler's Anemometer.

the vane, and moving in the same transverse line as the former, records the changes in the direction of the wind; and usually a third pencil, guided by a rain-gauge, registers on the same sheet the quantity of rain that has fallen. The preceding sketch, taken from the first half of a daily register-sheet, gives an idea of the kind of record made by an Osler's anemometer. The space between two upright lines indicates an hour; that between two horizontal lines, in the rain-register $\frac{1}{16}$ of an inch of rain, in the direction of the wind two cardinal points, and in the force of the wind 1 lb. of pressure on the square foot.

Thus, on the day in which these lines were traced, there was in the rain-register, brought over from the former account, between .10 and .15 of an inch; and during the twelve hours, the pencil had only risen one space, indicating a fall of .05, or $\frac{1}{20}$ of an inch, almost entirely between the hours of 3 and 4 in the morning, and immediately before 12 in the day. If the day had been very rainy, and the pencil had risen to the top of the register, it would have fallen immediately to the bottom of it, and begun a new account; and it might have done so several times in the course of the twelve hours. This would have been effected by the mechanism connected with the rain-gauge, which enables the gauge to empty itself each time that the pencil reaches the top of the rain-register. As regards the direction of the wind, it was, during the first six hours, south, veering slightly towards the east; and for the last six hours, it was tending decidedly towards the west, being between 10 and 11 nearly west. From the line marking the force of the wind, it will be seen that the day was stormy. Between 1 and 2, and at 11, the wind was blowing a very high gale, producing a pressure of upwards of 12 pounds on the square foot; and between the hours of 4 and 5, there was a decided lull, the wind being brisk, but not stormy (2 to 3 lb.). Both the hemispherical-cup anemometer and the pressure anemometer are equally indispensable in fully equipped observatories. The former registers only the amount of wind which passes over the place, but does not register the force

of those sudden and instantaneous gusts of wind to which storms and hurricanes owe their destructive energy. It must, however, be added that a tolerably correct means of registering the force of high winds remains yet to be found out.

The anemometer invented by W. H. Dines is especially suitable for the measurement of gusts. In it the wind, through tubes exposed to its force, acts on a recorder floating in water, which, rising and falling, indicates the varying force on a revolving sheet of paper.

All anemometers should be placed as high as practicable above the tops of tall buildings and out of reach of anything likely to influence the current; but the velocity thus obtained, it should be remembered, will be higher than at the surface of the earth. When anemometers are not available, the wind may be estimated and recorded arbitrarily without apparatus, as by the 'Beaufort Scale,' recognising 12 degrees, from a calm (3 miles an hour or less) to a hurricane (90 miles). See WIND; and references there.

Anemone, a genus of Ranunculaceæ, characterised by the acidity prevalent in this order. The species are numerous, and generally beautiful. Most

Wood Anemone (*A. nemorosa*).

of them flower early in spring. They are natives of temperate and cold climates, chiefly of the northern hemisphere. North America has a good many native species. One, *Anemone nemorosa*, the Wood Anemone, or wind-flower, is a common native of all parts of Britain, and its white flowers, externally tinged with purple, are an ornament of many a woodland scene and mountain pasture in April and May; and it is also common in parts of North America.

Another species, *Anemone pulsatilla*, the Pasque Flower, adorns chalky pastures in some parts of England at the same season. Its flowers are purple and externally silky. The Garden Anemone is a favourite florist's flower; the varieties, both single and double, are very numerous, but are chiefly traceable to two species, *Anemone coronaria* and *Anemone hortensis*, though other forms are constantly being introduced, of which *Anemone japonica* may be especially mentioned; and whole works have been published on them and their cultivation, which has long been most extensively carried on in Holland. The genus *Hepatica* is frequently included in *Anemone*. *Anemone tri-loba* (*Anemone hepatica*), with three-lobed leaves, is common in the Southern Alps. Varieties of different colours, and both single and double, are among the finest ornaments of our flower-borders in early spring. In cultivation, the soil around them should not be much disturbed.

Anemone, SEA, a popular name of Actinia and some allied genera of Actinozoa (q.v.). The term obviously refers to that gay flower-like appearance which has in other countries won for these forms titles such as 'sea-roses' and the like. They occur abundantly along our coasts, attached to rocks

or sometimes imbedded in sand, from low-water almost to high-water mark, and are very familiar objects both when expanded with spreading tentacles, and when contracted into a puckered conical knob. They are occasionally borne on floating objects, on the swinging seaweeds, or on other animals. Almost cosmopolitan in their distribution, they attain most magnificent development in the warmer seas, such as the Mediterranean. The sea anemone consists of a muscular tube, fixed by its expanded base, and with a rich crown of tentacles round the mouth. So far it is like a hydroid polyp, but the mouth margin is prolonged inwards to form an open stomach-cavity extending to near the base, and this inner tube is connected with the outer by vertical radiating mesenteries or membranous partitions. Not all of these mesenteries reach right across from outer wall to the stomach-tube, and below the termination of the latter they are all reduced in size so as to leave a wide basal space (see fig. 1). The chambers between the partitions communicate with one another, with the tubular cavities of the very variable tentacles, and with the general body-space. As usual, the body

Fig. 1.

A, *Anemonia sulcata*; B, *Cerianthus membranaceus*; C, *Bunodes gemmaceus* (closed); D, the same (open).

consists of an outer layer or *ectoderm*, an inner layer or *endoderm*, and a slightly developed median layer or *mesoderm*. None of the Actiniæ (*Malacodermata*) form any skeleton, but the body-wall is very thick and muscular, especially in the basal and oral regions. The outer layer of cells includes a large number of offensive elements—*nematocysts* or Thread-cells (q.v.), from which fine lassoes bathed in poison are thrown out on the least provocation, and are of great importance in numbing or killing both prey and enemies. The long uncoiled lassoes, usually much longer than the thread-cells which contained them, are too delicate to pierce the skin of the hand, but may be readily felt on cheek or tongue. Besides these, there are abundant sensitive cells scattered up and down in the outer layer, and especially frequent on the tentacles and mouth region. Externally these elements form fine hairs, which catch stimuli from the outside world, while internally they are in connection with a network of nerve fibres and cells lying beneath the skin. The *nervous system* is thus very diffuse. Developed *sense organs* are often present—e.g. round the margin of the mouth, in the form of azure spots like turquoise beads. These are apparently

rudimentary eyes. Both outer and inner layers form *muscle fibres* which lie apposed to the median sheath or mesoderm. The *mouth* is somewhat sunk below the level of the surrounding disc, and forms an elongated slit, which is occasionally constricted in the middle, so that one end serves for food coming in and the other for waste matter passing out. The mesenteries or partitions are fringed by special coiled filaments, which have been shown to digest food by taking the particles *holus-bolus* into their cells. The generative organs, are also borne on the sides of the mesenteries, and lastly, in some genera there are long, richly ciliated, thread-like weapons, which are beset with stinging-cells, and can be protruded through special apertures in the body-wall.

Sea anemones are very voracious, and feed on numerous forms of invertebrates. Johnston relates an interesting case of a sea anemone which had contrived to swallow a valve of *Pecten maximus* of the size of an ordinary saucer, and, having become divided into two compartments by the abnormal extension, had formed a second mouth and tentacle-wreath for the lower story. 'The individual became indeed a sort of Siamese twin, but with greater intimacy and extent in its union' (*British Zoophytes*, i. 235). With the exception of a few genera, the Actiniæ never form colonies, but remain as isolated individuals. They may attain very considerable size, and though that is usually covered by a few inches, they have been found in the Chinese Sea up to three feet in diameter. The sexes are separate or united. The eggs are fertilised in the body-cavity, and the Planula-like larvæ issue by the mouth. Division may also occur in varied fashion, and buds may also be formed externally or internally. Artificial division has also been frequently performed with success. Some forms attain considerable age, as in the classic instance of 'Grannie'—a common sea anemone (*Actinia mesembryanthemum*), which was taken from the Firth of Forth by Sir John Dalyell in 1828, and which died 4th August 1837. In six years this specimen produced 276 young. Sea anemones afford beautiful illustration of the association of different organisms. Some occur constantly on certain sponges in a more or less passive partnership, while others become associated with hermit

Fig. 2.—*Adamsia Rondeletii* borne by a Hermit Crab.

crabs in a close mutual union. On the one hand they are borne on the mollusc shell, or even on the claws of the hermit crab, and thus secure the advantages of locomotion, of a certain amount of protection, and of a share of the booty; while on the other hand they serve as protective organs

for their bearer, and are also useful in numbing, killing, or paralysing the desired prey. Such a mutual association is termed *Commensalism* (q.v.). Again, certain small fishes are found as commensals sheltered within the cavity of various sea anemones. But an even more intimate association is exhibited in those sea anemones which contain 'yellow cells.' These elements are minute single-celled plants which thrive in mutual partnership with the animal cells of the sea anemone. The carbonic acid given off by the animal cells is as useful to the minute plants as the oxygen and starch formed by the latter doubtless are to the sea anemone. Such an association is termed *Symbiosis* (q.v.). Sea anemones in many cases readily accommodate themselves to confinement in an aquarium, within which, however, they usually try to exterminate their fellow-prisoners.

It remains to notice some representative forms. The commonest British species is *Actinia mesembryanthemum*. It is hardly and readily kept in confinement, though accustomed to move about not a little by means of its muscular basal disc. The mouth margin bears a beautiful circlet of rudimentary eyes. *Anthea* or *Anemonia cereus* is also common in the south. It bears towards two hundred long, many-coloured, very mobile tentacles. *Actinia dianthus*, a large and extremely beautiful form, inhabits deep water; and the *Challenger* expedition brought up some species from very considerable depths (see *Challenger Report on Sea Anemones*). A large genus (*Discosoma*), measuring two feet across, is said to spread like a carpet over the Red Sea bottom, and even larger forms are known to occur. Some form for themselves a tubular sheath or other external protection. *Cereus crassicornis*, found abundantly on the south coasts of England, is one of the largest and most beautiful British forms, measuring about four inches in height, and fully more from tip to tip of expanded tentacles. The colour varies very greatly. A large number of forms (*Ilyanthus*, *Edwardsia*, *Peachia*, &c.) live in the sand, and have narrowed bases and elongated bodies. The best impression of the sea anemone group—apart from seeing the actual forms—is to be got by consulting the wonderfully magnificent monograph by Dr Angelo Andres, included in the series of reports on the fauna and flora of the Gulf of Naples. The *Challenger* report on the group ought also to be consulted. Abundant references will be found in these works.

An'eroid (formed from Gr. *an-*, 'not,' and *nēros*, 'wet'), the name given to a barometer invented in 1844 by M. Vidi of Paris, in which the pressure of the air is measured without the use of liquid, as in ordinary instruments. The face of the aneroid barometer, represented in fig. 1, has usually a diameter of about 5 inches, and the case behind, which contains the mechanism, a general idea of which is given in fig. 2, is about 2 inches deep. The pressure of the atmosphere acts upon a circular metal box, AA, about 3 inches in diameter, and $\frac{1}{4}$ of an inch deep, which has been nearly exhausted of air, and then soldered air-tight. The sides are corrugated in concentric rings, so as to increase their elasticity and strength, and one of them is fixed to the back of the brass case which contains the whole. The amount of exhaustion is such that if the sides of the box were allowed to take their natural position, they would be pressed in upon each other, and to prevent this they are kept distended, to a certain extent, by a strong spring, S, fixed to the case, which acts upon the head of the stalk, B, attached to the side next the face. When the pressure of the air increases, there being little or no air inside the box to resist it, the corrugated sides are forced inwards, and when it diminishes again, their elasticity restores them to

their former place; and thus the little box becomes a spring extremely sensitive to the varying pressure of the external atmosphere. Supposing the two

Aneroid Barometer.

sides pressed inwards, the end of the spring, E, will be drawn towards the back of the case, and carry with it the rod, EG, which is firmly fixed into it. EG, by the link GH, acts on the bent lever, HKL, which has its axis at K, so that, while the arm, KH, is pushed to the right, LK is moved downwards. By this motion, a watch-chain, O, attached at L, is drawn off the little drum, M, and the index-hand, PF, which is fixed to it, would move from the position represented in fig. 1 to one towards the right. When the contrary motion takes place, a hair-spring moves the drum and the hand in the opposite way. By this mechanism, a very small motion of the corrugated sides produces a large deviation of the index-hand, $\frac{1}{10}$ of an inch causing it to turn through 3 inches. The aneroid barometer is graduated to represent the inches of the mercurial barometer. Both from its small size and construction, it is extremely portable, and consequently a very useful instrument; but from its liability to change from time to time, it must be frequently compared with a good mercurial barometer. The 'Metallic Barometer' of M. Bourdon is a modification of the aneroid principle. See BAROMETER.

Aneurin, a Welsh poet (603), who, according to the received account, was the son of Caw ab Geraint, chief of the Otadini. Some have, however, identified him with Gildas, the British historian; whilst Mr Stephens makes him Gildas's son. After being educated at St Cadoc's College, at Llanancarvan, he joined the bardic order; was present at the battle of Cattraeth as bard and priest, and in his poem *Gododin*, he mentions the hardships he endured as a prisoner. When released, he returned to Llanancarvan, where it is believed he secured the friendship of a brother poet, Taliesin. In later life he lived with his brother, Nwython, in Galloway, and is said to have perished at the hands of Eidyn ab Einygan. His epic poem, the *Gododin*, which in its present form contains more than 900 lines, tells of the defeat of the Britons of Strathclyde by the Saxons at Cattraeth, but it has been found impossible to gain from it a satisfactory account of the British defeat, owing to the obscurity of the language and the difficulty of interpretation. Edward Davies asserts that the subject of the poem is the massacre of the Britons at Stonehenge in 472 A.D.; while Mr Stephens fixes the date of Cattraeth as 603, identifying it with the battle of Degstan or Dawstane in Liddesdale. Aneurin is also said to have written twelve stanzas on the Months. The *Gododin* was published with

an English version and notes in 1852, by Rev. J. Williams ab Ithel, and the text appears with a translation in W. F. Skene's *Four Ancient Books of Wales* (1866). The Cymmrodorion Society published, in 1885, an edition, with translation, by Thomas Stephens.

An'eurism (Gr. *aneurysma*, 'a dilatation') is a tumour containing blood, and communicating with the cavity of an artery. The sac of an aneurism may be formed in the first instance by one or more of the tunics of the vessel greatly stretched and thinned, generally the outer one, the two inner having given way. This is called a *true aneurism*, in contradistinction to the *false*, in which the sac is formed of cellular tissue condensed by the process of repair after a wound has been inflicted on the artery from without. Should the inner coat give way suddenly the blood may escape along the vessel between the coats (*dissecting aneurism*). True aneurism is almost always a result of Atheroma (see ARTERIES, Diseases of), and is most common in middle life. Aneurisms prove fatal by their pressure on some important part, or by bursting and allowing a sudden escape of blood. They are cured by the deposit, within the sac, of fibrin from the blood—a result the surgeon can promote by obstructing the artery above the aneurism by compression or by ligature; applying the latter close to the sac, if the aneurism is of the 'false' variety, but at a distance if it is the result of disease, or by electrolysis by means of needles introduced into the sac, or by passing into it a coil of fine wire. Internal aneurisms are treated by those remedies which moderate the heart's action, especially iodide of potassium, in conjunction with an abstemious and tranquil mode of life.

Very minute (or *miliary*) aneurisms are sometimes found in the arteries of the brain, a condition which may lead to apoplexy.

Arterio-venous aneurism is the name applied to the communication of an artery with a vein, either directly (aneurismal varix), or through an intervening aneurism (*varicose aneurism*). This condition is almost always the result of a wound injuring both artery and vein, and was at one time not uncommon as a consequence of bleeding being performed by non-professional persons. *Circosoid aneurism*, and aneurism *by anastomosis*, are names given to a rare disease, which consists in great dilatation, elongation, and tortuosity of the arteries affected.

Angara, a tributary of the Yenisei (q.v.).

Angioloencitis. See ADENTITIS.

Angel. Angels (Gr. *angeloi*, 'messengers') are a class of spiritual beings who appear in the Bible as the attendants of God, and especially as his messengers, and the medium of communication between him and men. (1) In the earlier historical books, the angel has sometimes no apparent form, but is only a voice, as it were; sometimes there is a form undistinguishable from that of an ordinary man, except by the conduct (Gen. xviii. xix.), although elsewhere at times there is something in his aspect that betrays the heavenly messenger (Judges, xiii. 6). The personality of the angel is completely overshadowed in his function; still he has a certain superhuman reality. But in any case he is simply the mouth-piece of God, so that in many passages 'the angel of God' is synonymous with 'God.' At the same time, the angel who specially represents God's presence to his people is distinguished from other angels who but carry out particular commissions. The distinction between the 'angel of the Lord,' who speaks in all things with full divine authority, and the subordinate angels, is based upon such passages as Gen. xviii.; Ex. xxxii. 34, and xxxiii. 2;

Is. lxiii. 9; and Gen. xlviii. 16. The belief that the special 'angel of the Lord,' as distinguished from created angels, was the *Logos* or second person of the Trinity, and that his appearance foreshadowed the incarnation, is still held by many theologians, but seems unknown to the Old Testament writers. (2) In the poetical and prophetic books, to the name of messengers are added new titles, as 'sons of God,' 'Saints,' or 'Holy Ones;' but they continue to discharge the same duties. (3) To express the majesty of the Almighty and his power in executing his will, the poetic imagination not only conceived of the angels as existing in vast numbers, but ascribed to them a certain warlike character. They are 'the sons of the Mighty,' who appear in war-chariots and form the army of God. Jehovah descends to battle with his hosts, and enters Zion in triumph amidst myriads of heavenly war-chariots. (4) The belief in guardian angels is merely a particular phase of the general idea. Israel has a special angel guide (Ex. xiv. 19, xxiii. 20); at a later period Michael is named their 'great prince' (Dan. xii. 1). Individuals also have their special guardian angels, whose sympathy and help they enjoy, and who joy or grieve with their joys and griefs (Matt. xviii. 10; Luke xv. 7, 10). It was believed that they sometimes assumed the form of their charge, becoming their double, as it were (Acts xii. 15). Not one, but an unlimited number attended on Jesus from his birth to the Ascension, were throughout his earthly life at his command, and will accompany him at his second coming. All this ministry to Jesus, as well as to the redeemed, might have been simply in obedience to the will of God; but they have also a personal interest in the success of the Gospel, and their ministry henceforth is specially connected with the work of salvation (Heb. i. 14; 1 Pet. i. 12), although they are inferior in glory to the Christian (Heb. ii. 16; 1 Cor. vi. 3). In Daniel, the 'angel interpreter' is Gabriel. Greece and Persia have special guardian angels.

A further development of the doctrine followed naturally from the idea of a host—its division into orders with chiefs, the greatest of whom are *arch-angels*. This idea, however natural from the analogy of an army, is a late conception, and first appears fully developed in Daniel. The ranks and classes of angels are discussed fully in the post-canonical and apocalyptic literature. In *Enoch*, cherubim and seraphim become distinct classes of angels, and new names are added to the names of the individual archangels. Angels have an important place in the Apocalypse. The seven angels (viii. 2) 'which stand before God' are Michael, Gabriel, Raphael, Uriel, Chamuel, Jophiel, and Zadkiel. The first three are the principal arch-angels, and in Christian art are often represented together, while the last three have never been generally recognised either in East or West. New features are the angels of the seven churches, interpreted, however, by many as mere human figures, and the association of the angels with cosmical forces—e.g. angels of fire and water (xiv. 18, xvi. 5). According to the rabbinical Jewish literature, there are 12 *mazzaloth* (signs of the zodiac), each with 30 chiefs of armies, each chief with 30 legions, each legion with 30 leaders, each leader with 30 captains, each captain with 30 under him, and each of these with 365,000 stars—and all 'ministering spirits' for Israel (cf. Heb. i. 14).

The Christian Fathers adopted to a great extent this elaborate hierarchy, adapting it to the Christian Church. The pseudo-Dionysius (4th or 5th century), in his *De Hierarchia Celesti*, gives nine orders, finding their names in the Old Testament, and in Eph. i. 21 and Col. i. 16: (1) Seraphim

(q.v.), Cherubim (q.v.), Thrones; (2) Dominations, Virtues, Powers; (3) Principalities, Arch-angels, Angels. One large sect of the Jews, that of the Sadducees, rejected the belief in the existence of angels as something entirely foreign to the Mosaic system. In the later stages of revelation, a group of angels came to be represented as having fallen from their primitive condition of innocence, and taken up a position of hostility to God. Punished by being degraded from their 'first estate,' they group themselves under the kingship of Satan, and continue to employ their activity in attempting to frustrate the good purposes of God (see *DEVIL*). Angel-worship is specially condemned by St Paul (Col. ii. 18), probably with reference to the doctrine of the Essenes. Cf. Rev. xix. 10. Protestants agree with the Catholic and the Eastern Church in the doctrine of angels, but do not permit the asking of their aid and intercession. Many modern critical theologians find the doctrine foreign to early Jewish religion, but derived from the Persians about the time of the Babylonish captivity; it would then be a part of the wider doctrine of spiritual existences pervading nature. Angels have been favourite subjects in Christian art. They are usually represented as youthful and beautiful male figures, with wings to symbolise their rapidity, and often with harps or other musical instruments to symbolise their incessant praise of God.

See Cremer's article 'Engel' in the Herzog-Hauck *Real-Encyklopädie* (vol. v. 1898); the handbooks of Old Testament theology by Oehler, Riehm, Dillmann; Oswald, *Angelologie* (1883); Mrs Jameson, *Sacred and Legendary Art*.

Angel, an old English gold coin, at first called more fully the *angel-noble*, because it was originally a new issue of the noble. It was so called

Angel of Edward IV.

from having upon its obverse the figure of the archangel Michael piercing the dragon. It was first coined in 1465 by Edward IV., when its value was 6s. 8d., from which it varied to 10s. under Edward VI. It was last coined by Charles I. It was the coin always presented to a person touched for the king's evil, and after it ceased to be coined, medals with the same device were substituted for it—hence called *touch-pieces*.

Angel-fish, a quaint and ugly fish belonging to the shark sub-order of Elasmobranchs (q.v.). It is often called the monk-fish, and is technically known as *Rhina Squatina* or *Squatina angelus*. The body usually measures about 4 feet in length, and is of a sandy gray colour above, and a dirty white beneath. The fish is in structure nearly allied to the sharks, but resembles the skate type, not only in its general habit, but also in its somewhat flattened body, and in its large pectoral fins, which, in their wing-like expansion, have won for this form its undeserved title of *angel-fish*. The gill-slits open laterally, however, and are only slightly covered by the bases of the fore-fins. The rounded head with terminal mouth, and wide spiracles behind the eyes, is wider than the body proper, and is separated from the pectoral fins by a short neck. The pelvic fins are situated just

behind the pectorals, and there are two unpaired dorsals towards the tail. The rough skin is richly beset with placoid scales, and exhibits spec-

Angel-fish.

ally large spines down the back and round the eyes. The teeth are conical. The fish has an exceedingly strong and peculiar ammonia-like smell. It occurs abundantly in European seas, hiding in the sandy bottom, and working havoc among the flat-fish. It is pretty common and specifically identical on the Atlantic coasts of North America. The young are born alive about midsummer. The coarse flesh is said to be nourishing. The rough skin has been long used for polishing purposes, for making instrument-cases and the like, and formerly had some repute as a powder for skin-diseases.

Angelica, a genus of plants of the natural order Umbelliferae (q. v.), by some botanists divided into two, *Angelica* and *Archangelica*. The species are mostly herbaceous and perennial, natives of the temperate and colder regions of the northern hemisphere. Wild *Angelica* (*A. sylvestris*) is a common plant in moist meadows, by the sides of brooks, and in woods in Britain and throughout many parts of Europe and Asia. The Garden *Angelica* (*A. archangelica* or *Archangelica officinalis*) is a biennial plant, becoming perennial when not allowed to

Angelica archangelica.

ripen its seeds. The whole plant, and especially the root, is aromatic and bitter, with a pleasant,

somewhat musky odour, and contains much resin and essential oil. The root was greatly valued in the middle ages as a specific against poisons, pestilential diseases, witchcraft, and enchantments, and was long employed as an aromatic stimulant and tonic, and in nervous and digestive ailments, but is now very little used in Britain. The root of *A. sylvestris*, sometimes substituted for it, is much weaker. The Garden *Angelica* was at one time also much cultivated for the blanched stalks, which were used as celery now is. The tender stalks and midribs of the leaves, candied, are still, however, a well-known article of confectionary, and an agreeable stomachic; the roots and seeds are employed in the preparation of gin and of 'bitters.' The plant is a very doubtful native of Britain, but is common in many parts of Europe, and even in Lapland and Iceland. Linnaeus describes the use of the dried root in Lapland as tobacco, and of the stem as a vegetable. The roots are occasionally ground and made into bread in Norway, and the Icelanders eat the stem and roots raw with butter. *A. sylvestris* has been used in tanning, and also as a yellow dye. Several species of angelica are natives of North America. The plant was called 'Angelic Herb' because of its repute as a defence against poison and pestilence.

Angelica Tree. See ARALIA.

Angelico, FRA, the commonest designation of the great friar-painter—in full, 'Il beato Fra Giovanni Angelico da Fiesole,' 'the blessed Brother John the angelic of Fiesole.' Born in 1387 at Vicchio, in the Tuscan province of Mugello, in 1407 he entered the Dominican monastery at Fiesole, in 1436 he was transferred to Florence, and in 1445 was summoned by the pope to Rome, where thenceforward he chiefly resided till his death in 1455. Of course, his frescoes, such as have not perished, are all in Italy—at Cortona, at Fiesole, in the Florentine convent of San Marco (now a museum), at Orvieto, and in the Vatican chapel of Nicholas V. Of his easel pictures, the Louvre possesses a splendid example, 'The Coronation of the Virgin,' and the London National Gallery (since 1860) a 'Glory,' or Christ with 265 saints. One supreme aim pervades all the creations of Fra Angelico—that of arousing devotional feeling through the contemplation of unearthly loveliness. He has been styled the 'protagonist of pietistic painting;' and estimates of his paintings will vary as do estimates of monasticism. Ruskin said that 'by purity of life, habitual elevation of thought, and natural sweetness of disposition, he was enabled to express the sacred affections upon the human countenance as no one ever did before or since. . . . His art is always childish, but beautiful in its childishness.' See books on him by Miss Phillimore (1881), Douglas (1901), Edgumbe Staley (1906), A. Pichon (1912), Hausenstein (1924).

Angellier, AUGUSTE JEAN (1848-1911), professor at Lille, was an original poet of power and accomplishment, and by his great book on Burns (1893) and other works did much to make English literature known in France.

Angeln, a district of Sleswick, between the Bay of Flensburg and the Schlei, noted for its fertility, and supposed to be the home from which came the Angles who invaded England in the 5th century. The principal place is Kappeln.

An'gelo, MICHAEL. See MICHELANGELO.

Angelus Bell, in Catholic countries, a bell rung at morning, noon, and sunset to invite the faithful to recite the Angelic Salutation (as in Millet's picture); see AVE MARIA.

Angelus Silesius (JOHANN SCHEFFLER; 1624-77), born at Breslau and bred a Protestant,

became a Catholic priest. His philosophy is a singular mixture of mystical pantheism and Christian morality, with a strong personal love of God. Some of his poems are in Protestant hymn-books.

Anger is displeasure or vexation accompanied by a passionate desire to break out in acts or words of violence against the cause of the displeasure; which should, of course, be a sentient being capable of feeling the infliction. Like most other emotions, it is accompanied by effects on the body, and in this case they are of a very marked kind. The arterial blood-vessels are highly excited; the pulse, during the paroxysm, is strong and hard, the face becomes red and swollen, the brow wrinkled, the eyes protrude, the whole body is put into commotion. The secretion of bile is excessive. In cases of violent passion, and especially in nervous persons, this excitement of the organs soon passes to the other extreme of depression; generally, this does not take place till the anger has subsided, when there follows a period of general relaxation. The original tendency to anger differs much in individuals according to temperament; but frequent giving way to it begets a habit, increases the natural tendency, and leaves its traces on the countenance. Anger is, often at least, prejudicial to health. It frequently gives rise to bile-fever, inflammation of the liver, heart, or brain, or even to mania. These effects follow immediately a fit of the passion; other evil effects come on, after a time, as the consequence of repeated paroxysms—such as paralysis, jaundice, consumption, and nervous fever. The milk of a mother or nurse in a fit of passion will cause convulsions in the child that sucks. The controlling of anger is a part of moral discipline. In a rudimentary state of society, its active exercise would seem to be a necessity; by imposing some restraint on the selfish aggressions of one individual upon another, it renders the beginnings of social co-operation and intercourse possible. See **EMOTIONS**; also Darwin, *The Expression of the Emotions in Man and Animals* (1872).

Angermanland, a former division of Sweden, now chiefly comprised in the government of Western-norland, extends along the Gulf of Bothnia, and is watered by the river Angerman. It exhibits great variety of wild and beautiful landscape, and is one of the best cultivated districts in Sweden. The river Angerman, 200 miles long, is, in its lower course, navigable for large ships. The chief town of the district is Hernösand (pop. 10,000).

Angermünde, a town of Prussia, on Lake Münde, 43 miles N.E. of Berlin by rail, with an iron-foundry and some miscellaneous manufactures; pop. 8000.

Angers (the ancient *Juliomagus* or *Andegavorum*), formerly the capital of the duchy of Anjou, and now of the French department of Maine-et-Loire, is situated on both sides of the navigable river Maine, not far from its junction with the Loire. It lies almost midway between Nantes and Tours, and is 214 miles S.W. of Paris by rail. Angers is the see of a bishop, and was the seat of a university founded in 1246, abolished in 1685; and it had a military college, at which the Earl of Chatham and the Duke of Wellington received part of their education. David the sculptor and Chevreul the chemist were natives. It has also a theological seminary, a medical school, lyceum, a botanical garden, a large picture-gallery, and a public library. The ancient castle of Angers, built by St Louis, stands on a projecting rock above the river. The cathedral is a fine building of the 13th century. Sail-making, wool and cotton spinning, and weaving are carried on, besides a trade in corn, wine, and garden produce. The neighbouring slate-quarries employ many men. Pop. 86,000.

Angerstein, JOHN JULIUS (1735–1823), a London underwriter, of Russian origin, whose collection of paintings, bought in 1824, formed the nucleus of the National Gallery.

Angina (Lat. *an'gīna*, 'quinsy;' but the term is usually pronounced *ang'īna* in England) is any form of choking throat affection (see **QUINSY**). In medical parlance it is customary to append an adjective specifying the nature of the affection; thus *Angina rheumatica* is rheumatic sore throat.

Angina Pectoris, sometimes called Heart-stroke or Breast-pang, is characterised by intense pain, accompanied by a sense of constriction, which occurs in paroxysms, beginning at the breastbone and radiating thence in different directions, but chiefly towards the left shoulder and arm. It causes extreme dread, which is shown in the countenance of the sufferer; the face becomes pale and drawn, and the extremities are cold; there is a feeling of impending suffocation, and yet the breathing is shallow, for the patient fears to make any movement, and remains in a fixed position, lest he should add to his distress; in many instances the pulse is small and hard. The attack gradually passes away, or may end in syncope, which is sometimes fatal. There are at times premonitory symptoms, such as nausea or faintness, but usually these are absent. It may appear without any apparent exciting cause, but more commonly the paroxysm follows some unwonted strain on the system, as, for example, excess in eating or drinking, muscular exertion, and mental emotions.

Angina Pectoris is associated with many different morbid conditions, amongst the more common being inflammations and degenerations of the heart and aorta, diseases of the valves, and of the nutritive arteries of the heart; in other cases it seems to be due to neuralgia, resulting from interference with the cardiac nerves by degenerative changes in the coronary vessels which accompany these nerves; in others, again, it may be induced by want of nutrition of the heart and its nerves through the diminished blood-supply caused by calcification of these coronary vessels. It has been noticed that the pulse is small and hard—that is, it is of high pressure—in many cases, and this speaks of a condition of tonic contraction of the arterioles. However produced, the pain originates in the terminal branches of the cardiac plexus of nerves, and is thence conducted by the sympathetic and pneumogastric nerves to the centres of sensory perception, from which it is referred to the associated areas of the shoulder, left arm, &c., in which the pain, therefore, appears to originate. The treatment of this disease requires before all else that the patient should shun excesses of every kind, and avoid over-exertion of body or undue mental excitement. During the attack it is absolutely necessary to adopt measures which will promptly relieve the suffering, and amongst such means the most useful and immediately necessary is the inhalation of nitrite of amyl, which in cases associated with high blood-pressure acts like a charm by dilating the arterioles. In cases where the seizure lasts a long time, the inhalation of ether or chloroform or the hypodermic injection of morphia gives relief. During the intermissions, the administration of the bromides and iodides has proved useful, and in cases where the tension tends to rise nitro-glycerine should be given, as it acts in a similar manner to nitrite of amyl, but more slowly and continuously. It is a matter of importance for the patient to have the necessary remedies at hand, and he should invariably carry small glass capsules containing nitrite of amyl for inhalation as necessary.

Angiosperms (Gr. *angeion*, 'a vessel,' and *sperma*, 'seed'), a term applied to Monocotyledons and Dicotyledons, in contrast to Gymnosperms (Conifers, Cycads, &c.). The distinction emphasised is that in angiosperms the ovules or future seeds are inclosed in a closed ovary, and fertilised through the medium of a stigma, while in gymnosperms the ovule is naked, and the pollen is applied directly to its surface. See OVULE.

Angkor. See CAMBODIA.

Angle, in Geometry, the inclination of two lines that cut or meet one another. If the lines are straight, the angle is *rectilinear*. The magnitude of an angle depends, not upon the length of the lines or legs, but upon the degree of their opening. If the legs are supposed closed, like a pair

A, right angle; B, acute angle; C, obtuse angle.

of compasses, and then gradually opened till they come into one straight line, they form a series of gradually increasing angles; when half-way between shut and straight, they contain a *right* angle. Any angle less than a right angle is called *acute*, and one greater is called *obtuse*. Angles are measured by degrees, of which a right angle contains 90. The angle made by two curved lines (*curvilinear*) is the same as the angle made by the tangents to the two curves at the point of intersection. Angles made by planes with one another can also be reduced to rectilinear angles. When three or more planes meet at the same point, the angular space included between them is called a *solid* angle.—For the *facial* angle of Camper, see SKULL.

Angler (*Lophius piscatorius*), a fish not uncommon on British shores, and sometimes called the *Fishing-frog*, sometimes, from its ugliness and voracity, the *Sea-devil*. It usually measures three feet or more in length. The head is enormously large, depressed, and spinous; the mouth is of

Angler-fish.

similar proportions (whence the Scottish name *Wide Gab*), and furnished with many sharp curved teeth, and with numerous worm-like lip-processes or barbules. The lower jaw is considerably longer than the upper. The body is narrow in comparison

with the great breadth of the head, and tapers rapidly to the tail. The whole fish is covered with a loose skin, almost without scales. There are two dorsal fins, which are spinous, and three anterior rays, regarded as belonging to the first dorsal, and freely articulated to the head, which are with great probability supposed to serve the animal as delicate organs of touch. The nostril tube is elongated into a membranous stalk, capable of spreading out like a cup at the upper end, and of being moved in every direction by a very numerous set of muscles; the bottom of the cup being divided into projecting leaflets, on which the olfactory nerve is finally distributed. The angler lives very much along the bottom, and, like the angel-fish, is said to attract its prey by dislodging worms from the sand. The dorsal filaments on the back of the head have been credited with attractive functions from before the time of Aristotle. The fish is exceedingly voracious, scores of undigested herrings, &c. having been frequently found in a single stomach. It is common in all North Atlantic coast waters. Other species are known in Mediterranean, Pacific, and South Atlantic waters.—The genus *Lophius* belongs to the order Acanthopterygii, and to the family Pediculati, remarkable for the elongation of the carpal bones, so as to form a distinct wrist, to the extremity of which the pectoral fin is articulated. By means of this development, these fishes are able to leap up suddenly to seize the prey which they observe above them; and some of them can hop about upon seaweeds or mud from which the water has retired. They do not suffer so quickly as most other fishes from being out of the water, their gill-opening being very small, and an angler has been often known to devour flounders or other fish which have been caught along with it. Most of the Pediculati are tropical.

Angles (*Angli*), a German tribe who occupied the country still called Angeln (q.v.), on the east of the Elbe, between Sleswick and Flensburg. Along with the Saxons and Jutes, they passed over in great numbers to Britain during the 5th century, and settled in East Anglia, Northumbria, and Mercia. Together with their kindred races, they formed the powerful people who came to be known as the Anglo-Saxons (q.v.). From them England derives its name (Lat. *Anglia*, Anglo-Saxon, *Engla-land*). After these migrations from Sleswick, the Danes from the north entered the deserted districts, and mingled with the Angles who remained there.

Anglesey, or ANGLESEA (Norse *Önguls-ey*, 'the island of the strait'), an island and county of Wales, on the north-west coast of that principality, being separated from the mainland by the Menai Strait (q.v.), which is spanned by the suspension bridge (1826) and by the tubular bridge (1850). Its form is that of an irregular triangle, the base facing the mainland. The extreme length of the island is 21 miles; its extreme breadth, 19; the coast-line measures about 80; and its area is 276 sq. m., or 176,630 acres. The climate is mild but foggy, especially in autumn; the soil, generally a stiff loam, varying with sandy and peaty earth; the general aspect of the island, flat and uninteresting, there being very little wood. The prevailing rock is mica schist; limestone ranges traverse the county; granite, marble, coal, serpentine, and soapstone are also found. The island is rich in minerals; the Parys and Mona copper-mines, near Amlwch, were opened in 1768. Lead ore, containing much silver, has also been found. The manufactures of Anglesey are inconsiderable. Agriculture, though still rather backward, has yet in recent years made considerable advance in the way of adopting means

of improvement. Increased attention has also been given to the breeding of cattle and sheep, which latter are a white-faced, hornless breed, the largest in North Wales. Anglesey was known to the Romans under the name of *Mona*. It was one of the chief seats of the Druidical power, which in 61 A.D. was all but destroyed by the Roman general, Suetonius Paulinus. The island was again subdued by Agricola, 76 A.D. Egbert conquered it in the 9th century; but the native princes afterwards recovered their dominion, establishing the seat of government at Aberffraw. It was finally subdued by Edward I. The ancient remains consist chiefly of dolmens, two of which, side by side, are in the park of Plas Newydd, the seat of the Marquis of Anglesey. At Holyhead are the remains of a Roman camp. The county is divided into three districts, called *cantref*s, each subdivided into two *commads*. The market-towns are Amlwch, Beaumaris, Holyhead, Llangefni, and Llanerch-y-medd. The first four united in sending one member to parliament till 1885, when they were merged in the county, which returns one member. Pop. (1861) 38,157; (1911) 50,928; (1921) 51,605.

Anglesey, HENRY WILLIAM PAGET, MARQUIS OF, born May 17, 1768, from Westminster passed to Christchurch, Oxford, and sat in parliament for the Carnarvon boroughs (1790-96) and for Milborne Port (1796-1810, off and on). Entering the army, he served with distinction in Flanders (1794), Holland (1799), and the Peninsula (1808); and in 1812 succeeded his father as Earl of Uxbridge. For his splendid services as commander of the British cavalry at Waterloo, where he lost a leg, he was made Marquis of Anglesey. In 1828 he was appointed lord-lieutenant of Ireland, at a period when that country was greatly agitated on the question of Catholic emancipation; and his advocacy of that measure procured his recall by Wellington in 1829. From 1830 to 1833 he held the same office under Lord Grey's administration; but O'Connell had now commenced his career of agitation, and the Marquis was forced to resort to severe coercive measures, which destroyed his earlier popularity. To him, however, Ireland is indebted for the Board of Education. From 1846 to 1852 he was Master-general of the Ordnance in the Russell ministry; and in the former year he was raised to the dignity of field-marshal. He died April 29, 1854.

Anglia, EAST, a kingdom founded by the Angles about the middle of the 6th century, in the eastern part of central England, in what forms the present counties of Norfolk and Suffolk—names which doubtless refer to a twofold settlement now entirely forgotten. At first to some extent dependent on Kent, and afterwards on Mercia, on the fall of the latter it was attached to Wessex, without, however, losing its own kings until the time of the Danish invasion, when it was seized by the invaders, and formed into a Danish kingdom under Guthrum (878). Edward, the son and successor of Alfred, after a long struggle forced the Danes to acknowledge him in 921. Under him Wessex grew to be England, and East Anglia was henceforward part and parcel of the kingdom. It was one of the four great earldoms of the kingdom under Canute. The modern see of Norwich is equivalent in extent to East Anglia, being an incorporation that took place about the end of the 9th century of the see founded for the Northfolk at Elmham (removed first to Thetford in 1078, then to Norwich in 1101), and that founded at Dunwich for the Southfolk.

Anglican, belonging to the Church of England (q.v.) and the other churches in communion with it at home and abroad; used specially of the moderate (or non-Romanising) High Church party.

Angling is the art of catching fish by rod, line, and hook, or by line and hook, the salient feature of the pursuit being the allurement of the prey by an attractive bait. The requisites for a successful angler are, knowledge of the haunts and habits of fish, dexterity in the use of tackle, and a patience much in excess of that required for most out-of-door amusements. The first qualification covers a wide field of study, involving, as it does, familiarity with the movements of fish at different seasons of the year, and in varying conditions of water; with the food preferred by different species; and with the characteristics of the fishes angled for. Much of this may be learned from the voluminous works upon the subject, but personal observation in the essentials of the sport, which has been designated 'the contemplative man's recreation,' is absolutely necessary for mastery of an art which is no less difficult than delightful. In like manner, skill in the use of rod and line depends more upon actual experiments by the water-side than acquisition of theories published by others.

The antiquity of angling is indicated in the well-known passage by the prophet Isaiah (xix. 8), variously translated in the past, but newly rendered in the revised version as 'The fishers also shall lament; and all they that cast angle into the Nile shall mourn.' Other Old Testament writers are also claimed as witnesses to the ancient practice of fishing with hook and line. That it was known to Egyptians, Greeks, and Romans as a pastime may be gathered from inscriptions, coins, frescoes, and other relics of the remote past; and Homer and Plutarch wrote with great accuracy of detail, and some sympathy, upon fish, and the methods in vogue in their days for catching them. A reference by Martial even suggests that fly-fishing, which is sometimes supposed to be a comparatively modern accomplishment, was known to the Romans in the 2d century. Oppian in his *Halieutics* vividly and enthusiastically describes in flowing hexameters the entire process of luring, striking, and playing a fish; and from the phrase, 'Above the tugging fish the acid'd reed bends,' it may be concluded not only that the ancient angler used a rod, but that it was supple and light.

The first printed English book on angling was the second edition of Dame Juliana Berners' (or Barnes) *Book of St Albans*, in which, to a previous chapter on hawking and hunting, was added a *Treatyse of Fysshynge with an Angle*. Shortly after this publication, Wynkyn de Worde (probably in 1450) issued the angling chapter as a separate book. In 1590 Leonard Mascall published *A Booke of fishing with hook and line, and of all other instruments thereto belonging*. John Denny's poetical *Secrets of Angling* followed in 1613. Thirty-eight years later Thomas Barker's *Art of Angling* appeared, to be succeeded in two years by Izaak Walton's *Complete Angler*, of which over a hundred editions have been published. The number of books on angling has marvellously increased since Westwood and Satchell's *Bibliotheca Piscatoria* (1833) catalogued 3158 editions and reprints of 2148 distinct works on fish and fishing.

Modern angling is pursued under vastly different conditions from those discussed by writers of the last century; and though all the rudimentary basis of the art remains what it has been for generations, altered circumstances have produced new developments. These arise from the growing facilities for travelling; the establishment of a cheap and extensive literature, periodical and permanent; the advance of science in the direction of fish-culture and mechanical appliances; and the better condition of the people. There is scarcely a large town in England without its angling clubs; and in the cities, the artisan anglers who fish such rivers

as Thames and Trent may be counted by thousands. To conclude, therefore, that there are a thousand anglers to-day where there was one fifty years ago would not be extravagant. The waters are, as a natural result, in constant danger of over-fishing, and can only be made to yield sport by systematic stocking; while the restrictive rules of societies and recent legislation have tended strongly to heighten the sportsmanlike qualities of angling, and to conserve our rivers and lakes.

The fish caught by angling in Great Britain are the Salmonidæ—such as the salmon, trout, char, and grayling; and the summer-spawners, or coarse fish—such as pike, perch, roach, chub, dace, bream, carp, barbel, tench, and gudgeon. Attempts, not always wise, are sometimes made to introduce new sporting fish into British waters; but for all practical purposes those enumerated are the game for which the angler seeks. The natural history of each species, and the special methods employed in their capture, are described in subsequent pages, under the names of the respective fishes; but there are many general principles which pertain to angling as an art, and which concern all classes of anglers in all parts of the world.

FISHING-TACKLE.—The soundest advice we can tender to the angler in the matter of fishing-tackle, is to cumber himself with as little as possible, and to see that what he uses is good, but of the simplest kind. If one might form an opinion from the bulky illustrated catalogues circulated by the tackle-makers, there is no class of sportsmen so full of fancies and crotchets as anglers; but every experienced fisherman knows that a large proportion of the pretty patented novelties are made to sell, rather than for sustained use. Much of the pleasure of angling is lost when the angler hampers himself with too much baggage. He requires a rod, line, winch, landing-net, lures, and receptacle for his fish; and should be able to carry all, and indulge in his sport, without fatigue from the burden strapped across his shoulders, and independent of assistance. As a rule, it is cheaper to buy than to make fishing-tackle; but it is most useful in case of emergencies to know how to whip a hook to gut, how to repair a broken rod, how to replace a lost ring, or how to dress an artificial fly. The tackle-book should therefore not be without a pair of small pliers, scissors, and waxed silk and thread. Having discovered the description of tackle that suits him and the branch of fishing in which he engages, the angler should not be tempted into acquisition of new-fangled gear merely because it is novel. All tackle should be carefully tested before use, and put away clean and dry after use. The habit of so dealing with it at the end of the day's sport should be a primary acquirement, from considerations alike of economy, efficiency, and comfort.

Rods depend entirely upon the branch of angling to be followed. The aim of every rod-maker should be, when suppleness is a necessity, to produce an implement as closely as possible resembling a natural growth like the bamboo, or the peeled wand used by boys in their novitiate; and, in rods where stiffness is an essential, a regularity of strength that shall produce a free balance. The heavy clumsy fishing-poles of our grandfathers are out of date, and cane rods assisted materially in the revolution, which was begun in the United States. For a while American makers were able to boast that they produced the lightest rods in the world—often, indeed, of almost toy-like elegance; but the greenheart rods for which the English and Scotch makers have always been famous hold their own to this day on the great salmon-rivers. The light and strong rod made of sections of cane,

joined with perfect accuracy, and known as the split-cane rod, was, however, soon imitated by English makers, and with a success that has placed them without a master. The great cost of these rods has hitherto stood in the way of universal adoption, but there is no gainsaying their superiority in lightness combined with power. Ten guineas for a salmon rod, and four or five guineas for a trout rod, are almost prohibitive prices, when, for less than half the money, serviceable implements of greenheart, hickory, or lancewood can be obtained. A very fair rod may be purchased for a guinea; and we have amongst a costly collection, a handy little trout rod, purchased for half a guinea in Edinburgh, that was preferred to the best of them, until an accident laid it on the rack.

For fly-fishing, a spliced rod is preferred by experienced anglers, especially for salmon; but the ferrule has become almost universal for general angling. The old-fashioned practice of hollowing the butt for receiving the spare top is not to be recommended, since it weakens the rod at a critical part, and destroys the balance. The main point in selecting a rod is to choose one that fits the hand, and to pay for utility and not for ornament. The ferrules should be stopped when the rod is idle; and the bag in which the joints are kept should be suspended from a loop, to prevent the warping of the pieces. The trouble arising from the sticking together of the ferruled joints may be avoided by rubbing the brazen parts with common soap. Standing rings are now preferred, and the ring at the end of the top joint is best with a revolving centre.

Lines and Winches are very important items of outfit, and they are made in inconceivable variety. The former are of plaited silk, cotton, hair and silk, hair and gut, and horse-hair. The plaited lines are either dressed or undressed, to make them waterproof and prevent kinking; but if dressed, the process should be of the best, otherwise the cracking of the dressing will be a constant source of irritation and mischief, and the work will have to be continually repeated. Any good angling-book will give recipes of line-dressing, but amateur dressing seldom answers. Plaited silk lines, tapered down to meet and correspond with the finest gut casts, and well dressed, are much used; they are stronger, susceptible of better casting than the silk-and-hair lines, which they have supplanted, and do not retain the water. In many districts, however, the more primitive lines are still used. Lines should be unwound from the winch at the earliest moment after use, and thoroughly dried before winding up; and at the river, the first thing that should be done after the line has been drawn through the rings, previous to the putting on of the gut cast, is to subject a few yards to a test for strength, so that no weak spot may be left, to lead, perhaps, to loss of both tackle and fish. Winches are of nickel-silver, bronze, vulcanite, brass, and wood, the cheapest being the last two. The most serviceable winches (called also *reels*, and in the north of England *pirns*) are those with least mechanism. For the general exercises of angling, nothing can beat a strongly-made bronze winch with a reasonable amount of check. For the commoner practices of bottom-fishing, the Nottingham winch, made of wood, and running without any check, is popular; but without care and acquirement of the trick of handling, the line will overrun and become entangled. The line for this winch should be the soft undressed silk, which also takes its name from the town of Nottingham.

Foot-lines are the lengths of finer material attached to the line for the more complete deception of fishes. They are either of gut or single horse-hair, and are essential to fly-fishing and other

forms of angling. When used by fly-fishers, this foot-line is sometimes called a collar, and sometimes a cast, and it is generally made of gut. Occasionally, and in special districts, horse-hair casts, tapering from a twist of three to a single strand, keep their ground, it being claimed for them that they have an elastic spring, and a freedom from glitter impossible with gut. Reliable hair casts are, however, difficult to procure, and when used are invariably home-made by some local specialist. Gut must be round, even, and transparent, and should be well moistened and straightened when wanted. Three yards is the orthodox length of a cast, but less will suffice for float-fishing. Of late years difficulty has been experienced in procuring the best gut for salmon-fishing, but the process of making drawn gut insures an unlimited supply of the finest casts for trouting.

Hooks are now made with eyes, both upturned and turned down. In the nomenclature and numbering of hooks there is great confusion, the makers of Redditch and Kendal using different terms. The standard patterns are Limerick, Kendal, Kirby, Sproat, Carlisle, and Round; and one of the newest forms is the Pennell-Limerick. Although the Japanese artificial flies are made with barbless hooks, and American anglers use a hook which is called barbless, it is impossible in this respect to improve upon the familiar plan. In very olden times hooks were clumsy and ill-contrived, but the necessity of a barb was well understood; and in the South Sea Islands, the native hooks, with their rude shanks of mother-of-pearl, have a sharp-curved fork of bone, answering the purpose of a barb.

Miscellaneous gear for angling comprises the basket or bag, without which the equipment would lack its most cherished object. Whether the basket or creel is better than the bag (waterproof or the reverse) is entirely a matter of taste. Boxes of thin, polished wood, of japanned tin, and of papier-mâché, are made for those who have lost faith in the common fishing-basket of commerce; but we might be content with a roomy creel, made, not of the closely-woven French work, but of the coarser fabric of osier, manufactured in Scotland and the English provinces. The fishy smell, which is an offence to many, can be removed from bag or basket by washing with Condy's fluid mixed with warm water. The landing-net is for securing the fish which is played out, but yet too heavy to be lifted from the water bodily by the line; and the gaff is for salmon and pike too large for treatment with a landing-net, which must be small to be portable, and capable of being hitched to the strap of the basket, and carried behind the shoulders ready for use. An angler's gear, however, is regulated by the character of his sport; and other articles, when necessary, will be incidentally mentioned hereafter, in the paragraphs concerning the three main branches into which angling, as practised in Great Britain, may be divided—viz. fly-fishing, spinning and live-baiting, and bottom-fishing.

Fly-fishing is the highest form of angling, and it is applied to the most valuable of our fresh-water fish. Many sportsmen consider any other kind of fishing as unworthy of consideration, forgetting that it is the lower branches which give the greatest happiness to the greatest number of anglers. Fly-fishing for salmon comes first, the salmon being most truly described as the king of fish. No one has yet discovered, though many conjectures have been offered, what the salmon supposes the artificial fly to be. As there are no insects at all resembling the gaudy affairs of fur and feather to which the salmon rises, it can scarcely welcome it as a dainty gift from the insect world;

and the most plausible theory is that the so-called artificial fly, bright with all the colours of the rainbow, and worked by jerks in the water, against or across stream, until the feathers and hackles move like the antennæ of some living creature, is seized in pure sport or from irresistible provocation. There are many problems unsolved with respect to salmon, and this is one of them. Salmon-flies vary in size from the Shannon or Tay pattern used in spring, with shank 3 inches long, to the low-water favourites scarce bigger than a trout-fly. To describe the different patterns would be to enumerate all the salmon rivers of the kingdom, since each district has its favourites. There is, perhaps, no more useful fly than the Jock Scott, originally a Tweed invention, but now tried everywhere. The Durham Ranger, Doctor, Popham, Wilkinson, Childers, Goldfinch (or Canary), and the Parson, are seldom missing from the salmon-fisher's book. Salmon-flies are sometimes, but should never be, whipped to strands of strong gut, which frays, and soon becomes treacherous at the head. The alternatives are a loop of gut, or the eyed-hook recently introduced. The salmon-rod should be from 16 to 18 feet long, according to the strength of the angler. The salmon-fly is cast across and down the pool, and worked deep or high, fast or slow, as the humour of the fish may determine.

Fly-fishing for trout is a more delicate operation. Until comparatively recent years, the fly-fisher attached two, three, or more flies to his cast, threw them lightly up or down stream, as his experience prompted, and allowed them to float naturally with the current. There are amongst trout-fishers an up-stream faction and a down-stream faction, the former using a short line and casting up the stream. By this method the angler is always behind the fish, minimises the risks of scaring, and is able to strike the hook firmly into, and not out of its mouth. This is doubtless the most scientific style when conditions are favourable. To allow the flies to drift down below is, however, easier, and in very rapid waters, is, indeed, the only way in which fishing can be carried on. The flies used are winged in imitation of the Ephemera and other water insects; hackled only, or so little dressed as to be termed spiders. These have their distinct uses on different streams. The latest school of fly-fishers advocate the floating or dry fly system, as practised on the crystal chalk streams of the south of England. One fly only is used, and this must be cast to float upon the surface of the stream with upright wings, in resemblance of the freshly hatched insect tribe that happens to be on the water. The custom is to cast over rising fish only, and not to work on speculation, as practitioners with the wet fly do. The justification for this system is the growing shyness of the trout; and upon choice rivers like the Itchen, Test, and Kennet, the method seems to be indispensable. On ordinary trout streams, however, flowing swiftly from hill sources, the common fashion pays best. Trout-flies are, like the larger lures for salmon, too numerous to particularise, but there are a few standard patterns that may be mentioned: Olive-dun, March Brown, Hare's Ear with Silver Twist, Red Spinner, Cow-dung, Needle-fly, Black Gnat, Red and Black Palmer, Governor, Alder, Black and Red Ants, Coachman, and Sedge. The stone-fly and May-fly (green and gray drake) are specialities, and confined to a brief season of the summer. When the rise of fly is good, the trout take it ravenously, and the largest bags of the year are then made. These insects are, however, peculiar to certain rivers, and so capriciously are they distributed that the upper half of a river will produce them while none are

hatched from the bed of the lower half. The artificial May-fly has large upstanding wings of drake, widgeon, teal, wood-duck, or Egyptian goose, with bodies of straw, india-rubber, bark, cork, and maize husk, besides the more ordinary wool and silk. The hooks are as large as those used for loch-flies in Scotland. The live May-fly and stone-fly are very killing; and north of the Trent the larva of the stone-fly, under the name of creper, is much used.

In fly-fishing, the golden rule is to keep as far as possible away from the water, and out of sight of the fish; to make the line and fly drop lightly and straight; to strike firmly, but gently; to keep the hooked fish well in hand, and get it down stream without delay. Eyed-hooks are recommended because they may be easily carried in a small box, because there is less risk from the fraying of gut at the head of the fly, and because the angler is always sure that the gut nearest the hook will be of the size required.

Spinning and live-baiting are processes in salmon, trout, perch, and pike fishing. Spinning may be accomplished with either an artificial or natural bait, the object being to present to the predatory fish angled for a colourable imitation of one of the smaller creatures swimming away from it. Spinning ranks next to fly-fishing as a sportsman-like branch of angling. The spinning baits revolve upon a swivel, and are best worked against stream. Artificial baits are made of silvered, gilt, or painted metal, gutta-percha, and in the phantom, a capital specimen of the class, of soleskin, which is filled with water by the action of spinning. They are moulded and painted to resemble small trout, gudgeon, or dace, and made to spin by a fan protruding from each side of the head, or by a tail on the principle of the archimedean screw. The spoon bait, which is often coloured red inside, spins by reason of its convex shape, and is a most killing bait for all fish of predaceous habits. Spinning traces are of stout gut, fine steel wire, or a mixture of gimp and wire, mounted on swivels. Many anglers fail in spinning through not sinking the bait deep enough, and through spinning too rapidly. The fish to be caught often lie low, and the angler must operate as much as he can upon their level. The larger baits will serve for both salmon and pike, the smaller artificial minnows for trout and perch.

Dace, trout, gudgeon, or sand-eel of seven inches long, or minnows, if for trout-fishing, are the natural baits most suitable for spinning flights. The 'flight' is a series of triangle, double, or single hooks, whipped upon gimp for pike, and strong or fine gut for salmon and trout fishing; and it must lie along the body of the bait, and be so affixed that it will spin something near nature. The advantage of the spinning bait is that the fish may be struck on the instant of seizing it. In pike-fishing, success may often be achieved, when straight spinning does not succeed, by causing the bait to spin irregularly. The movement is termed a 'wobble' by anglers, and is supposed to suggest a wounded fish trying to escape from danger. Wood's champion spinner produces a straight spin and requires no lead, the piece of straight wire that goes into the mouth and body of the bait being sufficiently weighted, while the rotatory motion is given by flanges at the head. Pennell's flight requires the usual lead, and receives its spin from the tail strongly curved by means of a large end hook. Upon no section of fishing-tackle has more ingenuity been spent than in the invention and registering of spinning baits. It can only be said that there is a wide field of choice, and that these spinning baits are as effective in salt as in fresh water angling.

Live baits, in the parlance of anglers, are small fish, shrimps, or frogs. They must be vigorous, and should be used with snap-tackle—that is to say, with hooks so arranged that they enter the mouth of the fish, and may be extracted to enable undersized or ill-conditioned specimens to be returned to the water. They are used with float, suspended at varying depths and travelling with the stream, or upon the *pater-noster*, a length of stout gut with single hooks attached to short lengths of gimp or gut. These are fastened to the foot-line by loops, and the hooks being baited, the apparatus sinks to the bottom by means of a weight at the end. The use of the gorge-hook for live baiting and trolling has long been discredited as unsportsmanlike.

Bottom-fishing is a term which is intended to express the art of angling for fish feeding on the beds of streams, and, though it is not precisely accurate, we may for expediency here adopt it. The rod for bottom-fishing is stiffer than that required by the fly-fisher; and the recreation is often sedentary. The exception is angling for trout in a clear stream with Stewart's tackle, a fine art in itself, which, strictly speaking, ought not to be included in this category. To kill a dish of trout when the water is at summer level and clearness, by ascending the stream, and deftly casting the worm upon Stewart's delicate tackle, is evidence of real proficiency in angling. No such skill is demanded in ordinary bottom-fishing, in which the shotted line is suspended by a float, and the hook, either on the bottom or at regulated depth above it, is baited with worms, maggots, caddis, bread paste, boiled wheat, rice, meal worms, or wasp grub. The once-fashionable perfumed baits are no longer believed in; but pastes sweetened with honey, or tinged with vermilion, are affected by many of the patient brethren to be met with sitting hopefully on the bank, or in the punt, waiting for a bite. Bottom-fishing is peculiarly the poor man's pleasure. Of free trout waters, save in Scotland, Ireland, and Wales, few remain; but the humble roach or perch fisher has his privileges still amongst what are called the coarse fish. The branch of bottom-fishing most directly answering to the name is that known as *legering*. With this method, the gut foot-line passes through a hole in a piece of flattened lead, and is kept in place by split shots a foot or so above the baited hook, which lies literally on the bed of the river, leaving the foot-line free to run through the weight to the limits of the small shot. Legering is principally used by barbel-fishers, but other fish are captured by it. For this amusement a hard, clean river-bed is essential. Angling is largely practised in the United States, Canada, Sweden, Norway, and Iceland. The trout and grayling streams of Germany and Austria are famous for sport. In India, the mahseer is the object of the angler's desire; in nearly the whole of the British dependencies trout have been now acclimatised.
